A number actually infinite (*i. e.* all whose units can be assigned, and yet is without limits) is a plain contradiction to all our ideas about numbers; for whatever number we can conceive, or have any proper idea of, is always determinate and finite; so that a greater after it may be assigned, and a greater after this; and so on, without a possibility of ever coming to an end of the addition or increase of numbers assignable: which inexhaustibility, or endless progression in the nature of numbers, is all we can distinctly understand by the infinity of number; and therefore to say that the number of any things is infinite, is not saying that we comprehend their number, but indeed the contrary; the only thing positive in this proposition being this, that the number of these things is greater than any number which we can actually conceive and assign. But then, whether in things that do really exist, it can be truly said that their number is greater than any assignable number; or, which is the same thing, that in the numeration of their units one after another, it is impossible ever to come to an end; this is a question about which there are different opinions, with which we have no business in this place: for all that we are concerned here to know is this certain truth; that after one determinate number we can conceive a greater, and after this a greater, and so on without end. And therefore, whether the number of any things that do or can really exist all at once, can be such that it exceeds any determinable number, or not, this is true; that of things which exist, or are produced successively one after another, the number may be greater than any assignable one; because, though the number of things thus produced that does actually exist at any time is finite, yet it may be increased without end. And this is the distinct and true notion of the infinity of a series; that is, of the infinity of the number of its terms, as it is expressed in the definition.

Hence it is plain, that we cannot apply to an infinite series the common notion of a sum, viz. a collection of several particular numbers that are joined and added together one after another, for this supposes that these particulars are all known and determined; whereas the terms of an infinite series cannot be all separately assigned, there being no end in the numeration of its parts, and therefore it can have no sum in sense. But again, if we consider that the idea of an infinite series consists of two parts, viz. the idea of something positive and determined, in so far as we conceive the series to be actually carried on; and the idea of an inexhaustible remainder still behind, or an endless addition of terms that can be made to it one after another, this is as different from the idea of a finite series as two things can be. Hence we may conceive it as a whole of its own kind, which therefore may be said to have a total value whether that is determinable or not. Now in some infinite series this value is finite or limited; that is, a number is assignable beyond which the sum of no assignable number of terms of the series can ever reach, nor indeed ever be equal to it, yet it may approach to it in such a manner as to want less than any assignable difference; and this we may call the value or sum of the series; not as being a number found by the common method of addition; but as being such a limitation of the value of the series, taken in all its infinite capacity, that if it were possible to add them all one after another, the sum would be equal to this number.

Again, in other series the value has no limitation; and we may express this, by saying the sum of the series is infinitely great; which indeed signifies no more than that it has no determinate and assignable value; and that the series may be carried such a length that its sum, so far, shall be greater than any given number. In short, in the first case we affirm there is a sum, yet not a sum taken in the common sense; in the other case we plainly deny a determinate sum to any sense.

Theorem I. In an infinite series of numbers, increasing by an equal difference or ratio (that is, an arithmetical or geometrical increasing progression) from a given number, a term may be found greater than any assignable number.

Hence, if the series increases by differences that continually increase, or by ratios that continually increase, comparing each term to the preceding, it is manifest that the same thing must be true, as if the differences or ratios continued equal.

Theorem II. In a series decreasing in infinitum in a given ratio, we can find a term less than any assignable fraction.

Hence, if the terms decrease, so as the ratios of each term to the preceding do also continually decrease, then the same thing is also true as when they continue equal.

Theor. III. The sum of an infinite series of numbers all equal, or increasing continually, by whatever differences or ratios, is infinitely great; that is, such a series has no determinate sum but grows so as to exceed any assignable number.

Demons. 1. If the terms are all equal, as $A : A : A$, &c. then the sum of any finite number of them is the product of A by that number, as An; but the greater n is, the greater is An; and we can take n greater than any assignable number, therefore An will be still greater than any assignable number.

Secondly, suppose the series increase continually (whether it does so infinitely or limitedly), then its sum must be infinitely great, because it would be so if the terms continued all equal, and therefore will be more so since they increase. But if we suppose the series increases infinitely, either by equal ratios or differences, or, by increasing differences or ratios of each term to the preceding; then the reason of the sums being infinite will appear from the first theorem; for in such a series, a term can be found greater than any assignable number, and much more therefore the sum of that and all the preceding.

Theor. IV. The sum of an infinite series of numbers decreasing in the same ratio is a finite number, equal to the quote arising from the division of the product of the ratio and first term, by the ratio less by unity; that is, the sum of no assignable number of terms of the series can ever be equal to that quote; and yet no number less than it is equal to the value of the series, or to what we can actually determine in it; so that we can carry the series so far, that the sum shall want of this quote less than any assignable difference.

Demonstration. To whatever assigned number of terms the series is carried, it is so far finite; and if the greatest term is l, the least A, and the ratio r, then the sum is $S = \frac{rl - \text{A}}{r-1}$. See Geometrical Progression.

Now, in a decreasing series from l, the more terms we actually raise, the last of them, A, becomes the lesser, and the lesser A be, $rl - \text{A}$ is the greater, and so also is $\frac{rl-\text{A}}{r-1}$: but rl—A being still less than rl, therefore $\frac{rl-\text{A}}{r-1}$ is still less than $\frac{rl}{r-1}$, that is, the sum of any assignable number of terms of the series is still less than the quote mentioned, which is, $\frac{rl}{r-1}$, and this is the first part of the theorem.

Again: The series may be actually continued so far, that $\frac{rl-\text{A}}{r-1}$ shall want of $\frac{rl}{r-1}$ less than any assignable difference; for, as the series goes on, A becomes less and less in a certain ratio, and so the series may be actually continued till A becomes less than any assignable number (by Theorem II.). Now $\frac{rl}{r-1} - \frac{rl-\text{A}}{r-1} = \frac{\text{A}}{r-1}$, and $\frac{\text{A}}{r-1}$ is less than A; therefore, let any number assigned be called N, we can carry the series so far till the last term A is less than N; and because $\frac{rl-\text{A}}{r-1}$ wants of $\frac{rl}{r-1}$, the difference $\frac{\text{A}}{r-1}$, which is less than A, which is also less than N, therefore the second part of the theorem is also true, and $\frac{rl}{r-1}$ is the true value of the series.

Scholium. The sense in which $\frac{rl}{r-1}$ is called the sum of the series, has been sufficiently explained; to which, however, we shall add this; that whatever consequences follow from the supposition of $\frac{rl}{r-1}$ being the true and adequate value of the series taken in all its infinite capacity, as if the whole were actually determined and added together, can never be the occasion of any assignable error in any operation or demonstration where it is used in that sense; because if it is said that it exceeds that adequate value, yet it is demonstrated that this excess must be less than any assignable difference, which is in effect no difference, and so the consequent error will be in effect no error: for if any error can happen from $\frac{rl}{r-1}$ being greater than it ought to be, to represent the complete value of the infinite series, that error depends upon the excess of $\frac{rl}{r-1}$ over that complete value; but this excess being unassignable, that consequent error must be so too; because still the less the excess is, the less will the error be that depends upon it. And for this reason we may justly enough look upon $\frac{rl}{r-1}$ as expressing the adequate value of the infinite series. But we are farther satisfied of the reasonableness of this, by finding in fact, that a finite quantity does actually convert into an infinite series, which happens in the case of infinite decimals. For example, $\frac{2}{3} = .6666$, &c. which is plainly a geometrical series from $\frac{6}{10}$ in the continual ratio of 10 to 1; for it is $\frac{6}{10} + \frac{6}{100} + \frac{6}{1000} + \frac{6}{10000}$, &c.

And reversely; if we take this series, and find its sum by the preceding theorem, it comes to the same $\frac{2}{3}$; for $l = \frac{6}{10}$, $r = 10$, therefore $rl = \frac{60}{10} = 6$; and $r - 1 = 9$; whence $\frac{rl}{r-1} = \frac{6}{9} = \frac{2}{3}$.

We have added here a table of all the varieties of determined problems of infinite, decreasing, geometrical progressions, which all depend upon these three things, viz. the greatest term l, the ratio r, and the sum S; by any two of which the remaining one may be found: to which we have added some other problems, wherein S — L is considered as a thing distinct by itself, that is, without considering S and L separately.

Theorem V. In the arithmetical progression 1, 2, 3, 4, &c. the sum is to the product of the last term, by the number of terms, that is, to the square of the last term, in a ratio always greater than 1 : 2, but approaching infinitely near it. But if the arithmetical series begins with 0, thus, 0, 1, 2, 3, 4, &c then the sum is to the product of the last term, by the number of terms, exactly in every step as 1 to 2.

Theorem VI. Take the natural progression beginning with 0, thus, 0, 1, 2, 3, &c and take the squares of any the like powers of the former series; as the squares, 0, 1, 4, 9, &c. or cubes, 0, 1, 8, 27; and then again take the sum of the series of powers to any number of terms, and also multiply the last of the terms summed by the number of terms, (reckoning always 0 for the first term;) the ratio of that sum to that product is more than $\frac{1}{n \times 1}$, (n being the index of the powers) that is, in the series of squares it is more than $\frac{1}{3}$; in the cubes more than $\frac{1}{4}$ and so on. But the series going on *in infinitum*, we may take in more and more terms without end into the sum; and the more we take, the ratio of the sum to the product mentioned grows less and less; yet so as it never can actually be equal to $\frac{1}{n \times 1}$, but approaches infinitely near to it, or within less than any assignable difference.

SERIOLA, a genus of plants belonging to the order of polygamia æqualis, and to the class of syngenesia, and in the natural system ranged under the 49th order, compositæ. The receptacle is paleaceous; the calyx simple; and the pappus is somewhat plumose. There are four species: 1. The levigata: 2. Æthnensis: 3. Cretensis: 4. Urens. The first is a native of the island of Candia, and flowers in July and August; the second is a native of Italy; and the fourth is a native of the south of Europe.

SERIPHIUM, a genus of plants belonging to the order of monogamia, and to the class of syngenesia. The calyx is imbricated; the corolla is monopetalous and regular, with one oblong seed under it. There are four species, natives of the Cape of Good Hope.

SERPENS. See Astronomy.

SERPENTES, in natural history, an order of the amphibia class, the characteristics of which are, a mouth breathing by the lungs only; body tapering; neck not distinct; jaws dilatable, not articulate; no feet, fins, or ears: motion undulatory. They are cast naked upon the earth, without limbs, exposed to every injury, but frequently armed with a poison the most deadly and horrible, which is contained in tubular fangs resembling teeth, placed without the upper jaw, protruded or retracted at pleasure, and surrounded with a glandular vesicle, by which this fatal fluid is secreted. (See POISONS.) But lest this tribe should too much encroach upon the limits of other animals, the benevolent Author of Nature has armed only about a fifth in this dreadful manner. The jaws are dilatable and not articulate, and the œsophagus so lax, that they can swallow without mastication, an animal twice or thrice as large as the neck. There are seven genera, viz. the

Achrochordus	Coecilia
Amphisbæna	Coluber
Anguis	Crotalus.
Boa	

The distinction of species in this numerous tribe is often peculiarly difficult. Linnæus persuaded himself that an infallible criterion might be found in the number of scaly plates on the abdomen and beneath the tail; and accordingly attempted in the Systema Naturæ to discriminate the species by this mark alone. Experience, however, has sufficiently shown that, though often highly useful in the investigation of these animals, it is yet by much too uncertain and variable to be permitted to stand as an established specific test.

The distinction of serpents into poisonous and innoxious can only be known by an accurate examination of their teeth; the fangs or poisoning teeth being always of a tubular structure, and calculated for the conveyance or injection of the poisonous fluid from a peculiar reservoir communicating with the fangs on each side of the head: the fangs are always situated in the anterior and exterior part of the upper jaw, and are generally, but not always, of much larger size than the other teeth; they are also frequently accompanied by some smaller or subsidiary fangs, apparently destined to supply the principal ones when lost, either by age or accident. The fangs are situated in a peculiar bone, so articulated with the rest of the jaw as to elevate or depress them at the pleasure of the animal. In a quiescent state they are recumbent, with their points directed inwards or backwards; but when the animal is inclined to use them as weapons of offence, their position is altered by the peculiar mechanism of the above-mentioned bone in which they are rooted, and they become almost perpendicular.

A general rule for the determination of the existence or non-existence of these organs in any species of serpent is proposed in a paper relative to the amphibia by Dr. Gray, and published in the Philosophical Transactions for the year 1788. The fangs, according to Dr. Gray, may be distinguished with great ease, and, as he believes also, with great certainty, by the following simple method. When it is discovered that there is something like teeth in the anterior and exterior part of the upper jaw, which situation he considers as the only one in which venomous fangs are ever found, let a pin or other hard body be drawn from that part of the jaw to the angle of the mouth; (which operation may, for greater certainty, be tried on each side.) If no more teeth are felt in that line, it may, he thinks, be fairly concluded, that those first discovered are fangs, and that the serpent is consequently venomous: if, on the contrary, the teeth first discovered are observed not to stand alone, but to be only a part of a complete row, it may as certainly be concluded that the serpent is not venomous. This rule, however, like most others, may have its exceptions, and perhaps the most legitimate test of real fangs in a serpent is their tubular structure, which may always be easily detected by the assistance of a proper magnifier. It is to be observed, that all serpents, whether poisonous or not, have besides the teeth, (whether fangs or simple teeth) in the sides of the upper jaw, two additional or interior rows, which are generally much smaller than the rest, and frequently scarcely visible: the general rule, therefore, is, that all venomous serpents have only two rows of true or proper teeth in the upper jaw, and that all others have four.

A head entirely covered with small scales is in some degree a character, but by no means an universal one, of poisonous serpents; as are also carinated scales on the head and body, or such as are furnished with a prominent middle line.

All serpents are in the habit of casting their skin at certain periods; in temperate regions annually; in the warmer perhaps more frequently. The serpents of the temperate and cold climates also conceal themselves, during the winter, in cavities beneath the surface of the ground, or in any other convenient places of retirement, and pass the winter in a state more or less approaching, in the different species, to complete torpidity. It may be added, that some serpents are viviparous, as the rattlesnake, the viper, and many others of the poisonous kind, while the common snake, and probably the major part of the innoxious serpents, are oviparous, depositing their eggs in a kind of string or chain in any warm and close situation, where they are afterwards hatched.

The broad undivided laminæ or scaly plates on the bellies of serpents are termed scuta, and the smaller or divided plates beneath the tail are called squamæ subcaudales, or subcaudal scales; and from these different kinds of laminæ the Linnæan genera of serpents are chiefly instituted.

SERPENTARIUS. See ASTRONOMY.

SERPENTINE, a mineral found in amorphous masses, forming strata, and even entire mountains. Its fracture is splintery, sometimes conchoidal. Specific gravity 2.57 to 2.71; feels soft and almost greasy; generally emits an earthy smell when breathed on. Its colours are various shades of green, yellow, red, grey, brown, and blue: commonly one or two colours form the ground, and one or more appear in spots or veins. Before the blowpipe it hardens, but does not melt. According to Mr. Chenevix it contains

34.5	magnesia
28.0	silica
23.0	alumina
4.5	oxide of iron
0.5	lime
10.5	water
101.0	

SERPICULA, a genus of plants belonging to the class of monœcia, and to the order of tetrandria. The male calyx is quadridentate, and the corolla consists of four petals. The female calyx is divided into four parts, and the pericarpium is a tomentose nut. There are two species, the verticillata and repens.

SERPULA, a genus of insects of the order vermes testacea. The generic character is: animal a terebella; shell univalve, tubular generally adhering to other substances; often separated internally by divisions at uncertain distances. There are 48 species.

SERRATULA, *saw-wort*, a genus of plants belonging to the class of syngenesia, and to the order of polygamia æqualis. In the natural system it is ranged under the 49th order, compositæ. The calyx is subcylindrical, imbricated; the scales of it pointed, but not spinous. There are 20 species: 1. The tinctoria, grows in woods and wet pastures. It dyes cloth of an exceedingly fine yellow colour, which stands well when fixed with alum. Goats eat this plant; horses are not fond of it; cattle, swine, and sheep, leave it untouched. 2. The alpina, or mountain saw-wort, grows on high mountains, and flowers commonly in July or August. 3. The arvensis, corn saw-wort, or way-thistle, grows in cultivated grounds and by way-sides, and flowers in July or August. When burned, it yields good ashes for making glass or fixed alkali.

SERROPALPUS, a genus of insects of the order coleoptera: the generic character is, antennæ setaceous; feelers four, unequal; the anterior ones longer deeply serrate, composed of four joints, the last joint very large, truncate, compressed, potelliform; the posterior ones subclavate: thorax margined, concealing the head, with a prominent angle on each side; head deflected; feet formed for digging. There are two species: the striatus is found on old wooden buildings in the evening in autumn.

SERTULARIA, in natural history, a genus belonging to the class of vermes, and to the order of zoophyta. The stem is radicated, fibrous, naked, and jointed; the florets are hydræ, and there is one each joint. This genus comprehends 42 species of corallines.

SERVANT. See MASTER AND SERVANT

SERVICE, in law, is a duty which a tenant, on account of his fee, formerly owed to his lord.

SERUM, a thin transparent liquor, which makes a considerable part in the mass of blood.

The specific gravity of human blood is, at a medium, 1.0527. Mr. Fourcroy found the specific gravity of bullock's blood, at the temperature of 60°, to be 1.056. The blood does not uniformly retain the same consistence in the same animal, and its consistence in different animals is very various. It is easy to see that its specific gravity must be equally various.

When blood, after being drawn from an animal, is allowed to remain for some time at rest, it very soon coagulates into a solid mass of the consistence of curdled milk. This mass gradually separates into two parts; one of which is fluid, and is called serum; the other the coagulum, has been called cruor, because it alone retains the red colour which distinguishes blood. This separation is very similar to the separation of curdled milk into curds and whey.

The proportion between the cruor and serum of the blood varies much in different animals, and even in the same animal in different circumstances. The most common proportion is about one part of cruor to three parts of serum; but in many cases the cruor exceeds or falls short of this quantity; the limits of the ratios of these substances to each other appear, from a comparison of the conclusions of most of those who have written accurately on the subject, to be 1 : 1 and 1 : 4; but the first case must be very rare indeed.

The cause of this spontaneous decomposition of blood has not hitherto been ascertained. The coagulation takes place equally in close vessels and in the open air, whether the blood is allowed to cool, or is kept at the temperature at which it issues from the animal; neither is the coagulation prevented by diluting it with water.

1. The serum is of a light greenish-yellow colour; it has the taste, smell, and feel, of the blood, but its consistence is not so great. Its mean specific gravity is about 1.0287. It converts syrup of violets to a green, and therefore contains an alkali. On examination, Rouelle found that it owes this property to a portion of soda. When heated to the temperature of 156°, the serum coagulates, as Harvey first discovered. It coagulates also when boiling water is mixed with it; but if serum is mixed with six parts of cold water, it does not coagulate by heat. When thus coagulated, it has a greyish-white colour, and is not unlike the boiled white of an egg. If the coagulum is cut into small pieces, a muddy fluid may be squeezed from it, which has been termed the serosity. After the separation of this fluid, if the residuum is carefully washed in boiling water and examined, it will be found to possess all the properties of coagulated albumen. The serum, therefore, contains a considerable proportion of albumen. Hence its coagulation by heat, and the other phenomena which albumen usually exhibits.

If serum is diluted with six times its weight of water, and then boiled to coagulate the albumen, the liquid which remains after the separation of the coagulum, if it is gently evaporated till it becomes concentrated, and then is allowed to cool, assumes the form of a jelly, as was first observed by De Haen. Consequently it contains gelatine.

If the coagulated serum is heated in a silver vessel, the surface of the silver becomes black, being converted into a sulphuret. Hence it is evident that it contains sulphur; and Proust has ascertained that it is combined with ammonia in the state of a hydrosulphuret.

If serum is mixed with twice its weight of water, and after coagulation by heat, the albumen is separated by filtration, and the liquid slowly evaporated till it is considerably concentrated, a number of crystals are deposited when the liquid is left standing in a cool place. These crystals, first examined by Rouelle, consist of carbonat of soda, muriat of soda, besides phosphat of soda and phosphat of lime. The soda exists in the blood in a caustic state, and seems to be combined with the gelatine and albumen. The carbonic acid combines with it during evaporation.

Thus it appears that the serum of the blood contains albumen, gelatine, hydrosulphuret of ammonia, soda, muriat of soda, phosphat of soda, and phosphat of lime. These component parts account for the coagulation occasioned in the serum by acids and alcohol, and the precipitation produced by tan, acetat of lead, and other metallic salts.

With respect to the other part, the cruor, or clot, as it is sometimes called, is of a red colour, and possesses considerable consistence. Its mean specific gravity is about 1.245. If this cruor is washed carefully by letting a small jet of water fall upon it till the water runs off colourless, it is partly dissolved, and partly remains upon the searce. Thus it is separated into two portions, viz. (1.) A white, solid, elastic substance, which has all the properties of fibrina. 2. The portion held in solution by the water, which consists of the colouring matter, not however in a state of purity, for it is impossible to separate the cruor completely from the serum.

We are indebted to Bucquet for the first precise set of experiments on this last watery solution. It is of a red colour. Bucquet proved that it contained albumen and iron. Menghini had ascertained, that if blood is evaporated to dryness by a gentle heat, a quantity of iron may be separated from it by the magnet. The quantity which he obtained was considerable; according to him, the blood of a healthy man contains above two ounces of it. Now, as neither the serum nor the fibrina extracted from the cruor contains iron, it follows of course, that the water holding the colouring matter in solution must contain the whole of that metal.

This watery solution gives a green colour to syrup of violets. When exposed to the air, it gradually deposits flakes, which have the properties of albumen. When heated, a brown-coloured scum gathers on its surface. If it is evaporated to dryness, and then mixed with alcohol, a portion is dissolved; and the alcoholic solution yields by evaporation a residuum, which lathers like soap in water, and tinges vegetable blues green; the acids occasion a precipitate from its solution. This substance is a compound of albumen and soda. Thus we see that the watery solution contains albumen, iron, and soda.

Fourcroy and Vauquelin have ascertained that the iron is combined with phosphoric acid, and in the state of subphosphat of iron; thus confirming an opinion which had been maintained by Sage, and announced as a fact by Gren. If the residuum obtained by evaporating the watery solution of the colouring matter of blood to dryness is burnt in a crucible, there will remain a deep-red ferruginous substance, amounting to 0.045 of the blood employed. Nitric acid digested on this residuum dissolves a portion, which is phosphat of iron, and is precipitated white by ammonia, but assumes a red colour when treated with pure potass. When lime-water is poured into the potass employed, phosphat of lime precipitates. By this treatment they ascertained, that $\frac{19}{26}$ of the residuum consisted of subphosphat of iron. Now phosphat of iron is soluble in acids, but insoluble in water; when treated with pure alkalies, it loses a portion of its acid, assumes a red colour, and is converted into subphosphat. Hence it is evidently the soda of the blood which reduces it to that state, or at least maintains it in that state. Subphosphat of iron readily dissolves in albumen and in serum.

When new-drawn blood is stirred briskly round with a stick, or the hand, the whole of the fibrina collects together upon the stick, and in this manner may be separated altogether from the rest of the blood. The red globules, in this case, remain behind in the serum. It is in this manner that the blood is prepared for the different purposes to which it is put; as clarifying sugar, making puddings, &c. After the fibrina is thus separated, the blood no longer coagulates when allowed to remain at rest, but a spongy flaky matter separates from it, and swims on the surface.

When blood is dried by a gentle heat, water exhales from it, retaining a very small quantity of animal matter in solution, and consequently having the odour of blood. Blood dried in this manner being introduced into a retort and distilled, there comes over first a clear watery liquor, then carbonic acid gas, and carbonat of ammonia, which crystallizes in the neck of the retort; after these products there come over a fluid oil, carbonated hydrogen gas, and an oily substance of the consistence of butter. The watery liquor possesses the property of precipitating from sulphat of iron a green powder: muriatic acid dissolves part of this powder, and there remains behind a little Prussian blue. Consequently this watery liquor contains both an alkali and prussic acid.

9216 grains of dried blood being put into a large crucible, and gradually heated, at first became nearly fluid, and swelled up considerably, emitted a great many fetid fumes of a yellowish colour, and at last took fire and burned with a white flame, evidently owing to the presence of oil. After the flame and the fumes had disappeared, a light smoke was emitted, which affected the eyes and the nose; it had the odour of prussic acid, and reddened moist paper stained with vegetable blue. At the end of six hours, when the matter had lost five-sixths of its substance, it melted anew, exhibited a purple flame on its surface, and emitted a thick smoke. This smoke affected the eyes and nostrils, and reddened blue paper, but it had not the smell of prussic acid. When a quantity of it was collected and examined, it was found to possess the properties of phosphoric acid. The residuum amounted to 181 grains; it had a deep-black colour, and a metallic brilliancy; and its particles were attracted by the magnet. It contained no uncombined soda, though the blood itself, before combustion, contains it abundantly; but water extracted from it muriat of soda; part of the remainder was dissolved by muriatic acid, and of course was lime; there was besides a little silica, which had evidently been separated from the crucible. The iron had been reduced during the combustion.

Such are the properties of blood, as far as they have been hitherto ascertained by experiment. We have seen that it contains the following ingredients:

1. Water,
2. Fibrina,
3. Albumen,
4. Gelatine,
5. Hydrosulph. of ammonia,
6. Soda,
7. Subphosphat of iron,

8. Muriat of soda,
9. Phosphat of soda,
10. Phosphat of lime.

Besides benzoic acid, which has been detected by Proust.

But our knowledge of this singular fluid is by no means so complete as it ought to be; a more accurate analysis would probably discover the presence of other substances, and enable us to account for many of the properties of blood which at present are inexplicable.

SESAMUM, *oily grain*, a genus of plants belonging to the class of didynamia, and to the order of angiospermia, and in the natural system ranging under the 20th order, luridæ. The calyx is divided into five parts. The corolla is companulated, the tube of which is nearly the length of the calyx; the throat is inflated, and very large; the border is divided into five parts, four of which are spreading and nearly equal; the fifth is the lowest and largest. There are four filaments, and the rudiments of a fifth. The stigma is lanceolated, and the capsule has four cells. There are only three species, the orientale, indicum, and luteum. 1. The orientale has ovate, oblong, entire leaves. It is an annual, and grows naturally on the coast of Malabar and in the island of Ceylon; rising with an herbaceous four-cornered stalk, two feet high, sending out a few short side-branches. After the flowers are past, the germen turns to an oval acute-pointed capsule, with four cells, filled with oval compressed seeds, which ripen in autum. 2. The indicum, with trifid lower leaves, grows naturally in India: this is also an annual plant; the stalk rises taller than that of the former; the lower leaves are cut into three parts, which is the only difference between them. The first sort is frequently cultivated in all the eastern countries, and also in Africa, as a pulse; and of late years the seeds have been introduced into Carolina by the African negroes, where they succeed extremely well. The inhabitants of that country make an oil from the seed, which will keep good for many years, without having any rancid smell or taste, but in two years become quite mild; so that when the warm taste of the seed, which is in the oil when first drawn, is worn off, they use it as a sallad-oil, and for all the purposes of sweet oil. The seeds of this plant are also used by the negroes for food; which seeds they parch over the fire, and then mix them with water, and stew other ingredients with them, which makes a hearty food. Sometimes a sort of pudding is made of these seeds, in the same manner as with millet or rice, and is by some persons esteemed, but is rarely used for these purposes in Europe.

From nine pounds of this seed which came from Carolina, there were upwards of two quarts of oil drawn, which is as great a quantity as has been obtained from any vegetable whatever. This might occasion its being called the oily grain.

SESELI, *meadow-saxifrage*, a genus of plants belonging to the class of pentandria, and to the order of digynia, and in the natural system ranging under the 45th order, umbellatæ. The umbels are globular; the involucrum consists of one or two leaflets; the fruit is egg-shaped and streaked. There are fifteen species. The montanum grows naturally in France and Italy; the glaucum is a native of France; the ammoides and tortuosum grow in the south of Europe; and the hyppomarathrum is a native of Austria.

SESSION, in law, denotes a sitting of justices in court upon their commission: as the session of oyer and terminer, &c.

SESSIONS, *quarter*. The session of the peace is a court of record holden before two or more justices, whereof one is of the quorum, for the execution of the authority given them by the commission of the peace, and certain statutes and acts of parliament.

The justices shall keep their sessions in every quarter of the year at least, and for three days if need be; to wit, in the first week after the feast of St. Michael, in the first week after the Epiphany, in the first week after Easter, and in the first week after St. Thomas, and oftener if need be.

Any two justices, one whereof is of the quorum, by the words of the commission of the peace, may issue their precept to the sheriff to summon a session for the general execution of their authority; and such session, holden at any time within that quarter of a year, is a general quarter-session. 4 Burn, 181. And such precept should bear teste, or be dated, fifteen days before the return. Nels. Intr. 35.

The sheriff also shall cause a jury to appear at such days and places as the said justices, or such two or more of them as aforesaid, shall appoint.

There are many offences, which, by particular statutes, belong properly to this jurisdiction, and ought to be prosecuted in this court: as the smaller misdemeanors against the public or commonwealth, not amounting to felony; and especially offences relating to the game, highways, alehouses, bastard children, the settlement and provision of the poor, vagrants, servants' wages, apprentices, and popish recusants. Some of these are proceeded upon by indictment; and others in a summary way, by motion and order thereupon; which order may, for the most part, unless guarded against by any particular statute, be removed into the court of king's bench by certiorari, and be there either quashed or confirmed.

SESSIONS *for weights and measures*. In London, four justices from among the mayor, recorder, and aldermen, (of which the mayor or recorder to be one) may hold a session to enquire into offences of selling by false weights and measures, contrary to the statutes; and to receive indictments, punish the offenders, &c.

SESTERCE, a silver coin in use among the Romans. See COIN.

Some authors make two kinds of sesterces: the less, called sestertius, in the masculine gender; and the great one, called sestertium, in the neuter, the latter containing a thousand of the former.

Sesterce, or sestertius, was also used by the antients for a thing containing two wholes and a half of another, as *as* was taken for any whole or integer.

SESUVIUM, a genus of plants belonging to the class of icosandria, and to the order of trigynia. The calyx is coloured, and divided into five parts; there are no petals; the capsule is egg-shaped, three-celled, opening horizontally about the middle, and containing many seeds. There is only one species, the portulacastrum, purslane-leaved sesuvium, which is a native of the West Indies.

SET-OFF, is when the defendant acknowledges the justice of the plaintiff's demand on the one hand, but on the other sets up a demand of his own to counterbalance that of the plaintiff, either in the whole, or in part: as if the plaintiff sues for 10*l*. due on a note of hand, the defendant may set-off 9*l*. due to himself for merchandize sold to the plaintiff. 3 Black. 304.

The action in which a set-off is allowable upon the statutes 2 and 8 G. II. c. 22 and 24, are debt, covenant, and assumpsit, for the non-payment of money; and the demand intended to be set-off, must be such as might have been made the subject of one or other of these actions. A set-off, therefore, is never allowed in actions upon the case, trespass, replevin, &c. nor of a penalty, in debt on bond conditioned for the performance of covenants, &c. nor of general damages in covenant or assumpsit; but where a bond is conditioned for the payment of an annuity, a set-off may be allowed. A debt barred by the statute of limitations, cannot be set-off; and if it is pleaded in bar to the action, the plaintiff may reply the statute of limitations; or if given in evidence, on a notice of set-off, it may be objected to at the trial. Tidd's Pract. K. B.

SETON. See SURGERY.

SETTING, in the sea-language. To set the land or the sun by the compass, is to observe how the land bears on any point of the compass, or on what point of the compass the sun is. Also when two ships sail in sight of one another, to mark on what point the chased bears, is termed setting the chase by the compass.

SEVENTH, *septima*, in music. A dissonant interval called by the Greeks heptachordon, because it is formed of seven sounds, or six diatonic degrees. There are four kinds of sevenths. The minor seventh, composed of four tones (three majors and one minor), and two major semitones; the major seventh, composed diatonically of five tones (three majors and two minors), and a major semitone; the diminished seventh, consisting of three tones (two minors and one major), and three major semitones; and the superfluous seventh, containing five tones (three minors and two majors), a semitone major, and a semitone minor.

SEWER, a passage or gutter made to carry water into the sea or a river, whereby to preserve the land, &c. from inundations and other annoyances. The business of the commissioners of sewers, or their office in particular, is to repair sea-banks and walls, survey rivers, public streams, ditches, &c. and to make orders for that purpose.

These commissioners have likewise authority to make enquiry of all nuisances or offences committed by the stopping of rivers, erecting mills, not repairing banks, bridges, &c. and to tax persons chargeable for the amending of defaults that tend to the obstruction or hindrance of the free passage of the water through its antient courses. They may not only make a rate and assessment for repairs, but also may decree lands to be sold, in order to levy charges assessed, upon nonpayment thereof, &c. But the decrees of the commissioners are to be certified into chancery, and have the king's assent, to be bind-

4

ing, and their proceedings are subject to the jurisdiction of the king's bench. In the making of a rate or tax, the commissioners are to assess every owner or possessor of lands in danger of receiving any damage by the waters, equally according to the quality of their lands, rents, and numbers of acres, and their respective portions and profits, whether it is of pasture, fishing, &c. And where no persons or lands can be known that are liable to make repairs of banks and sewers, then the commissioners are to rate the whole level. The 3. Jac. I. ordains that all ditches, banks, bridges, and water-houses, within two miles of London, adjoining to, and falling into the Thames, shall be subject to the commissioners of sewers. Also the lord-mayor, &c. may appoint persons in that case to have the power of commissioners of sewers. Persons breaking down sea-banks, whereby lands are damaged, are adjudged to be guilty of felony; and removing piles, &c. forfeit twenty pounds by 6 and 10 Geo. II. c. 32.

SEXAGESIMALS, or SEXAGESIMAL FRACTIONS, fractions whose denominators proceed in a sexagecuple ratio; that is, a prime, or the first minute, $=\frac{1}{60}$; a second $=\frac{1}{3600}$; a third $=\frac{1}{216000}$.

Antiently there were no other than sexagesimals used in astronomy, and they are still retained in many cases, though decimal arithmetic begins to grow in use now in astronomical calculations. In these fractions, which some call astronomical fractions, the denominator being always sixty, or a multiple thereof, is usually omitted, and the numerator only written down, thus, 4°, 59′, 32″, 50‴, 16⁗, is to be read four degress, fifty-nine minutes, thirty-two seconds, fifty thirds, sixteen fourths, &c.

SEXANGLE, in geometry, a figure having six sides, and consequently six angles.

SEXTANS, a sixth part of certain things. The Romans having divided their *as* into twelve ounces, or unica, the sixth part of that, or two ounces, was the sextans.

Sextans was also a measure which contained two ounces of liquor, or two cyathi. See MEASURE.

SEXTANT, in mathematics, denotes the sixth part of a circle, or an arch comprehending sixty degrees.

The word sextant is more particularly used for an astronomical instrument made like a quadrant, excepting that its limb only comprehends sixty degrees. The use and application of the sextant is the same with that of the quadrant. See QUADRANT.

SEXTON, a church-officer, whose business is to take care of the vessels, vestments, &c. belonging to the church, and to attend the minister, churchwardens, &c. at church. He is usually chosen by the parson only.

SEXTUPLE, *sestuplo*, in music, denotes a mixed sort of triple which is beaten in double time, now called compound common time.

SHADOW, in optics, a privation or diminution of light, by the interposition of an opake body; or it is a plane where the light is either altogether obstructed, or greatly weakened, by the interposition of some opake body between it and the luminary. See OPTICS.

SHADOW. See GEOGRAPHY.

SHAFT *of a column*, in building, is the body thereof between the base and capital so called from its straightness.

SHAGREEN, or CHAGREEN, in commerce, a kind of grained leather, prepared, as is supposed, of the skin of a species of squalus, or hound-fish, called the shagree, or shagrain, and much used in covering cases, books, &c.

It is imported from Constantinople, Tauris, Tripoli, Algiers, and from some parts of Poland, where it is prepared in the following manner: the skin being stretched out is first covered over with mustard-seed, which is bruised upon it; and being thus exposed to the weather for some days, it is then tanned.

The best is of a brownish colour, as the white sort is the worst. It is extremely hard; yet, when steeped in water, it becomes soft and pliable; and being fashioned into case-covers, it readily takes any colour, as red, green, yellow, black, according to the fancy of the workman.

SHAKLES, in a ship, are the rings with which the ports are shut fast, by lashing the port-bar to them. There are also shakles put upon bilbow-bolts, for confining the men who have deserved corporal punishment.

SHAMBLES, among miners, a sort of niches, or landing-places, left at such distances in the adits of mines, that the shovelmen may conveniently throw up the ore from shamble to shamble, till it comes to the top of the mine.

SHAMMY, or CHAMOIS LEATHER, a kind of leather dressed either in oil or tanned, and much esteemed for its softness, pliancy, and being capable of bearing soap without hurt.

The real shammy is prepared of the skin of the chamois-goat.

The true chamois leather is counterfeited with common goat, kid, and even sheep-skin; the practice of which makes a particular profession, called by the French chamoisure. The last is the least esteemed, yet so popular, and such vast quantities prepared, especially about Orleans, Marseilles, and Tholouse, that it may not be amiss to give the method of preparation.

The manner of chamoising, or of preparing sheep, goat, or kid-skins in oil, in imitation of chamois:

The skins being washed, drained, and smeared over with quick-lime, on the fleshy side, are folded in two, lengthwise, the wool outwards, and laid on heaps, and so left to ferment eight days; or if they had been left to dry after flaying, for fifteen days.

Then they are washed out, drained, and half-dried, laid on a wooden leg or horse, the wool stripped off with a round staff for the purpose, and laid in a weak pit, the lime whereof had been used before, and had lost the greatest part of its force.

After twenty-four hours they are taken out, and left to drain twenty-four more; then put into another strong pit. This done, hey are taken out, drained, and put in again by turns; which begins to dispose them to take oil; and this practice they continue for six weeks in summer, or three months in winter; at the end whereof they are washed out, laid on the wooden leg, and the surface of the skin on the wool side peeled off, to render them the softer; then made into parcels, steeped a night in the river, in winter more; stretched six or seven over one another on the wooden leg; and the knife passed strongly on the fleshy side, to take off any thing superfluous, and render the skin smooth.

Then they are stretched as before in the river, and the same operation repeated on the wool side; then thrown into a tub of water with bran in it, which is brewed among the skins till the greatest part sticks to them; and then separated into distinct tubs, till they swell and rise of themselves above the water.

By this means, the remains of the lime are cleared out; they are then wrung out, hung up to dry on ropes, and sent to the mill, with the quantity of oil necessary to fill them: the best oil is that of stock-fish.

Here they are first thrown in bundles into the river for twelve hours, then laid in the mill-trough, and fulled without oil till they are well softened; then oiled with the hand, one by one, and thus formed into parcels of four skins each, which are milled and dried on cords a second time, then a third; then oiled again and dried.

This process is repeated as often as necessity requires; when done, if there is any moisture remaining, they are dried in a stove, and made up in parcels wrapped up in wool; after some time they are opened to the air, but wrapped up again as before, till such time as the oil seems to have lost all its force, which it ordinarily does in twenty-four hours.

The skins are then returned from the mill to the chamoiser to be scoured; which is done by putting them into a lixivium of wood-ashes, working and beating them in it with poles, and leaving them to steep till the lye has had its effect; then wrung out, steeped in another lixivium, wrung again, and this repeated till all the grease and oil is purged out. They are then half-dried, and passed over a sharp-edged iron instrument, placed perpendicular in a block, which opens, softens, and makes them gentle: lastly, they are thoroughly dried, and passed over the same instrument again, which finishes the preparation, and leaves them in form of chamois.

Kid and goat-skins are chamoised in the same manner as those of sheep, excepting that the hair is taken off without the use of any lime; and that when brought from the mill they undergo a particular preparation called ramalling, the most delicate and difficult of all the others.

It consists in this, that as soon as brought from the mill they are steeped in a fit lixivium; taken out, stretched on a round wooden leg, and the hair scraped off with the knife; this makes them smooth, and in working cast a fine nap. The difficulty is in scraping them evenly.

SHANKER, or CHANCRE. See MEDICINE.

SHARP, in music, a character, the power of which is to raise the note before which it is placed half a tone higher than it would be without such a preposition.

SHARPING-CORN, a customary gift of corn, said to be half a bushel for a plough-land, which the farmers pay in some parts of England to their smith, every Christmas, for sharping their plough-irons, harrow-tines, &c.

SHAWIA, a genus of the class and order syngenesia polygamia segregata. The calyx.

is intricate, with five or six seeds, three interior larger; corolla five-cleft; seed one, oblong. There is one species of New Zealand.

SHEATHING, in the sea language, is the casing that part of a ship which is to be under water, with fir-board of an inch thick; first laying hair and tar, mixed together, under the boards, and then nailing them on, in order to prevent worms from eating the ship's bottom.

SHEATS, in a ship, are ropes bent to the clews of the sails; serving, in the lower sails, to haul aft the clews of the sail; but, in top sails, they serve to haul home the clew of the sail close to the yard-arm.

SHEEP. See Ovis.

Sheep. Any person who shall feloniously drive away, or feloniously steal, any sheep or lamb; or wilfully kill any sheep or lamb, with a felonious intent to steal the carcase or any part thereof; or assist or aid in committing any of the said offences; shall be guilty of felony without benefit of clergy. 14 Geo. II. c. 6.

Any person who shall apprehend and prosecute to conviction any such offender, shall have a reward of 10*l.* for which purpose he shall have a certificate signed by the judge, before the end of the assizes, certifying such conviction, and where the offence was committed, and that the offender was apprehended and prosecuted by the person claiming the reward; and if more than one claim it, he shall therein appoint what share shall be paid to each claimant. And on tendering such certificate to the sheriff, he shall pay the same within a month, without deduction, or forfeit double, with treble costs; to be allowed in his accounts, or be repaid him out of the treasury.

And any person who shall in the night time, maliciously and willfully maim, wound, or otherwise hurt any sheep, whereby the same is not killed, shall forfeit to the party grieved treble damages, by action of trespass, or on the case.

And by 28 Geo. III. c. 38, every person who shall export any live sheep or lambs, shall forfeit 3*l.* for every sheep or lamb, and shall also suffer solitary imprisonment for three months, without bail, and until the forfeiture is paid; but not to exceed twelve months for such non-payment; and for every subsequent offence 5*l.* a piece, and imprisonment for six months, and until the forfeiture is paid; but not to exceed two years for the non-payment thereof. And all ships and vessels employed therein shall be forfeited.

SHEERING, or Shearing, in woollen manufacture, is the cutting off with large sheers the too long nap, in order to make the cloth more smooth and even. See the article Cloth.

Sheering, in the sea language, When a ship is not steered steadily, they say she sheers, or goes sheering; or, when at anchor, she goes in and out by means of the current of the tide, they also say she sheers.

SHEERS, in a ship, are two masts set across at the upper end of each other; a contrivance generally used for setting or taking out the masts of a ship, where there is no hulk to do that office.

SHEFFIELDIA, a genus of plants belonging to the class of pentandria, and to the order of monogynia. The corolla is bell-shaped; the filaments are ten, of which every second is barren; the capsule consists of one cell, which has four valves. There is only one species, the repens, of New Zealand.

SHEKEL, in Jewish antiquity, an antient coin, worth 2*s.* 3¼*d.* sterling. See the article Coin.

Some are of opinion that the Jews had two kinds of shekels, viz. the common one, already taken notice of, and the shekel of the sanctuary; which last they made double the former, and consequently equal to 4*s.* 6½*d.* But most authors make them the same; so that the shekel of the sanctuary, according to them, is only worth 2*s.* 3¼*d.*

SHELF, among miners, the same with what they otherwise call fast ground, or fast country; being that part of the internal structure of the earth, which they find lying even and in an orderly manner; and evidently having retained its primitive form and situation, unmoved by the waters of the general deluge, while the circumjacent and upper strata have plainly been removed and tossed about.

SHELLS, chemically examined, are found like bones to consist of calcareous salts united to a soft animal matter; but in them the lime is united chiefly to carbonic acid, whereas in bones it is united to phosphoric acid. In shells, the predominating ingredient is carbonat of lime; but in bones it is phosphat of lime. Mr. Hatchett has divided shells into two classes. The first are usually of compact texture, resembling porcelain, and have an enamelled surface, often finely variegated. These are denominated porcelaneous shells: to this class belong the various species of veluta, cypræa, &c. The second class consists of shells usually covered with a strong epidermis, below which lies the shell in layers, and composed entirely of the substance well known by the name of mother of pearl. They have been distinguished by the name of mother of pearl shells. The shell of the fresh-water muscle, the heliotis iris, the turbo olearius, are examples of such shells. The shells of the first class contain a very small portion of soft animal matter: those of the second contain a very large proportion. Hence the difference of their component parts.

Porcelaneous shells, when exposed to a red heat, crackle, and lose the colour of their enamalled surface. They emit no smoke nor smell; their figure continues unaltered; their colour becomes opaque white, tinged partially with pale grey. They dissolve when fresh with effervescence in acids, and without leaving any residue; but if they have been burnt there remains always a little charcoal. The solution is transparent, gives no precipitate with ammonia or acetat of lead; of course it contains no sensible portion of phosphat or sulphat of lime. Carbonat of ammonia throws down an abundant precipitate of carbonat of lime. Porcelaneous shells, then, consist of carbonat of lime cemented together with a small portion of animal matter, which is soluble in acids, and therefore resembles gelatine.

2. Mother of pearl shells when exposed to a red heat, crackle, blacken, and emit a strong fetid odour. They exfoliate, and become partly dark grey, partly a fine white. When immersed in acids they effervesce at first strongly; but gradually more and more feebly, till at last the emission of air-bubbles is scarcely perceptible. The acids take up only lime, and leave a number of their membranaceous substances which still retain the form of the shell.

The genera of shells are extremely numerous, and the species under many of them are also very much so. However, they may be divided into three series or orders; the first comprehending all shells formed only of one piece, called by authors simple or univalve shells; the second, all those shells composed of two parts or valves, under the name of bivalves; and the third, all shells composed of several parts or valves, under the name of multivalves.

This method takes in all the shells hitherto known; the land, as well as the sea-shells, being all comprehended under one or other of these divisions; indeed, all the recent land-shells are univalves, but the fossil shells belong to all the three series.

Shells, *fossil*, those found buried at great depths in earth, and often immersed in the hardest stones. These fossil shells, as well as those found lying on the sea-shore, make an excellent manure, especially for cold clayey lands.

Shells, in the military art. See Gunnery.

SHERARDIA, a genus of the monogynia order, in the tetrandia class of plants, and in the natural method ranking under the 47th order, stellatæ. The calyx is small, quadridentate; the corolla monopetalous, long, and funnel-shaped. The two seeds are naked, and crowned with the calyx. There are three species, viz. 1, arvensis; 2, muralis; 3, fruticosa.

SHERIFF. As keeper of the king's peace, the sheriff is the first man in the county, and superior in rank to any nobleman therein, during his office. He may apprehend and commit to prison all persons who break the peace, or attempt to break it, and may bind any one in a recognizance to keep the king's peace. He may, and is bound ex officio, to pursue and take all traitors, murderers, felons, and other misdoers, and commit them to gaol for safe custody. He is also to defend his county against any of the king's enemies, when they come into the land; and for this purpose, as well as for keeping the peace and pursuing felons, he may command all the people of his county to attend him; which is called the posse comitatus, or power of the county; which summons, every person above fifteen years of age, and under the degree of a peer, is bound to attend upon warning, on pain of fine and imprisonment. Yet he cannot exercise the office of a justice of the peace, for then this inconvenience would arise, that he should command himself to execute his own precepts. 1 Black. 343.

The sheriff has a jurisdiction both in criminal and civil cases; and therefore he has two courts: his torn for criminal cases, which is the king's court; the other is his county court, for civil causes, and this is the court of the sheriff himself. 3 Salk. 322.

When the new sheriff is appointed and sworn, he ought at or before the next county court, to deliver a writ of discharge to the old sheriff; who is to set over all the prisoners in the gaol, severally by their names, (together with all the writs,) precisely, by view and indenture between the two sheriffs, wherein must be comprehended all the actions which the old sheriff has against every prisoner, though the executions are of record. And till the delivery of the prisoners to the new sheriff, they remain in the custody of the old sheriff, notwithstanding the letters patent of appointment, the writ of discharge, and the writ of delivery. Neither is the new sheriff obliged to receive the prisoners, but at the gaol. But the office of the old sheriff ceases, when the writ of discharge is brought to him. Wood, b. 1. c. 7.

By 3 Geo. I. c. 15. it shall not be lawful for any person to buy, sell, let, or take to farm. the office of under-sheriff, or deputy-sheriff, or seal-keeper, county-clerk, shire-clerk, gaoler, bailiff, or any other office pertaining to the office of high sheriff, or to contract for any of the said offices, on forfeiture of 500*l.* one moiety to his majesty, the other to such as shall sue in any court at Westminster, within two years after the offence.

Provided that nothing in this act shall hinder any high sheriff from constituting an under-sheriff, or deputy-sheriff, as by law he may; nor to hinder the under-sheriff in any case of the high sheriff's death, when he acts as high sheriff, from constituting a deputy; nor to hinder such sheriff, or under-sheriff, from receiving the lawful perquisites of his office, or from taking security for the due answering the same; nor to hinder such sheriff, or under-sheriff, deputy-sheriff, seal-keeper, &c. from accounting to the high sheriff for all such lawful fees as shall be by them taken, nor from giving security so to do; or to hinder the high sheriff from allowing a salary to his under-sheriff, &c. or other officers.

And if any sheriff shall die before the expiration of his year, or before he is superseded, the under-sheriff shall nevertheless continue in his office, and execute the same in the name of the deceased, till another sheriff is appointed and sworn; and the under-sheriff shall be answerable for the execution of the office during such interval as the high sheriff would have been; and the security given by the under-sheriff and his pledges shall stand a security to the king, and all persons whatsoever, for the performing his office during such interval. Id.

SHIELD, an antient weapon of defence, in the form of a light buckler, borne on the arm, to turn off lances, darts, &c.

Shield, in heraldry, the escutcheon or field on which the bearings of coats of arms are placed.

SHILLING, an English silver coin. See the article Coin.

It is observed that there were no shillings or twelve-penny pieces in England till the year 1504, when they were first coined by Henry VIII.

SHINGLES, in building, small pieces of wood, or quartered oaken boards, sawn to a certain scantling, or, as is more usual, cleft to about an inch thick at one end, and made like wedges, four or five inches broad, and eight or nine inches long.

Shingles are also used instead of tiles or slates, especially for churches and steeples; however this covering is dear; yet where tiles are very scarce, and a light covering is required, it is preferable to thatch; and where they are made of good oak, cleft, and not sawed, and well seasoned in water and the sun, they make a sure, light, and durable covering. The building is first to be covered all over with boards, and the shingles nailed upon them.

SHIP, a general name for all large vessels, particularly those equipped with three masts and a bowsprit; the masts being composed of a lower-mast, top-mast, and top-gallant-mast: each of these being provided with yards, sails, &c. Ships, in general, are either employed for war or merchandize.

Ships *of war* are vessels properly equipped with artillery, ammunition, and all the necessary martial weapons and instruments for attack or defence. They are distinguished from each other by their several ranks or classes, called rates, as follows: ships of the first rate mount from 100 guns to 110 guns and upwards; second rate, from 90 to 98 guns; third rate, from 64 to 74 guns; fourth rate, from 50 to 60 guns; fifth rate, from 32 to 44 guns; and sixth rate, from 20 to 28 guns. Vessels carrying less than 20 guns are denominated sloops, cutters, fire-ships, and bombs.

In Plate I. Ship-building, fig. 1, is the representation of a first-rate, with rigging, &c. the several parts of which are as follow:

Parts of the hull.

A The cat head
B The fore chain wales or chains
C The main-chains
D The mizen-chains
E The entering port
F The hause-holes
G The poop-lantern
H The chess-trees
I The head
K The stern

Ships of war are fitted out either at the expence of the state or by individuals. Those fitted out at the public expence are called king's ships, and are divided into ships of the line, frigates, sloops, &c. Ships of war fitted out by individuals are called privateers.

Ship, *hospital*, a vessel fitted up to attend on a fleet of men of war, and receive their sick or wounded; for which purpose her decks should be high, and her ports sufficiently large. Her cables ought also to run upon the upper deck, to the end that the beds or cradles may be more commodiously placed between decks, and admit a free passage of the air to disperse that which is offensive or corrupted.

SHIP, *merchant*, a vessel employed in commerce to carry commodities of various sorts from one port to another. The largest merchant-ships are those employed by the different companies of merchants who trade to the East Indies. They are in general larger than our 40-gun ships, and are commonly mounted with 20 guns on their upper deck, which are nine-pounders; and six on their quarter-deck, which are six-pounders.

SHIP, *store*, a vessel employed to carry artillery or naval stores for the use of a fleet, fortress, or garrison.

SHIP, *transport*, is generally used to conduct troops from one place to another. Besides the different kinds of ships above-mentioned, which are denominated from the purpose for which they are employed, vessels have also, in general, been named according to the different manner of rigging them. It would be an endless, and at the same time an unnecessary task, to enumerate all the different kinds of vessels with respect to their rigging; and therefore a few only are here taken notice of. Fig. 2 is a ship which would be converted into a bark by stripping the mizen-mast of its yards and the sails belonging to them. If each mast, its corresponding top-mast and top-gallant-mast, instead of being composed of separate pieces of wood, were all of one continued piece, then this vessel with very little alteration would be a polacre. Fig. 3, a brig; fig. 4, a ketch; fig. 5, a schooner; fig. 6, a sloop; fig. 7, a dogger; fig. 8, a galley under sail; fig. 9, ditto rowing.

Ships are also sometimes named according to the different modes of their construction. Thus we say, a cat-built ship, &c.

To ship, is either used actively, as to embark any person or put any thing aboard ship; or passively, to receive any thing into a ship; as, "we shipped a heavy sea at three o'clock in the morning."

To ship also implies to fix any thing in its place; as, to ship the oars, that is, to put them in their rowlocks; to ship the swivel guns, is to fix them in their sockets; to ship the handspokes, &c.

Management of ships at single anchor, is the method of taking care of a ship while riding at single anchor in a tide-way, by preventing her from fouling her anchor, &c. The following rules for this purpose will be found of the utmost consequence:

Riding in a tide-way, with a fresh of wind, the ship should have what is called a short or windward-service, say 45 or 50 fathoms of cable, and always sheered to windward, not always with the helm hard down, but more or less so according to the strength or weakness of the tide. It is a known fact, that many ships sheer their anchors home, drive on board of other ships, and on the sands near which they rode, before it has been discovered that the anchor had been moved from the place where it was let go.

When the wind is cross, or nearly cross, off shore, or in the opposite direction, ships will always back. This is done by the mizen-topsail, assisted, if needful, by the mizen-staysail; such as have no mizen-topsail commonly use the main topsail, or if it blows fresh, a top-gallant-sail, or any such sail at the gaff.

In backing, a ship should always wind with a tawt cable, that it may be certain the anchor is drawn round. In case there is not a sufficiency of wind for that purpose, the ship should be hove apeak.

Riding with the wind afore the beam, the yards should be braced forward; if abaft the beam, they are to be braced all aback.

If the wind is so far aft that the ship will not back (which should not be attempted if, when the tide eases, the ship forges ahead, and brings the buoy on the lee quarter), she must be set ahead: if the wind is far aft, and blows fresh, the utmost care and attention are necessary, as ships riding in this situation often break their sheers and come to windward of their anchors again. It should be observed, that when the ship lies in this ticklish situation, the after-yards must be braced forward, and the fore-yards the contrary way; she will lie safe, as the buoy can be kept on the lee quarter; or suppose the helm is aport, as long as the buoy is on the larboard quarter. With the helm thus, and the wind right aft, or nearly so, the starboard main and fore braces should be hauled in. This supposes the main braces to lead forward.

When the ship begins to tend to leeward, and the buoy comes on the weather-quarter, the first thing to be done is to brace about the fore-yard; and when the wind comes near the beam, set the fore-staysail, and keep it standing until it shakes; then brace all the yards sharp forward, especially if it is likely to blow strong.

If lying in the aforesaid position, and she breaks her sheer, brace about the main-yard immediately; if she recovers and brings the buoy on the lee or larboard-quarter, let the main-yard be again braced about; but if she comes to a sheer the other way, by bringing the buoy on the other quarter, change the helm and brace the fore-yard to.

Riding leeward tide with more cable than the windward service, and expecting the ship will go to windward of her anchor, begin as soon as the tide eases to shorten in the cable. This is often hard work: but it is necessary to be done, otherwise the anchor may be fouled by the great length of cable the ship has to draw round; but even if that could be done, the cable would be damaged against the bows or cut-water. It is to be observed, that when a ship rides windward tide the cable should be cackled from the short service towards the anchor, as far as will prevent the bare part touching the ship.

When the ship tends to windward and must be set ahead, hoist the fore-staysail as soon as it will stand; and when the buoy comes on the lee quarter, haul down the fore-staysail, brace to the fore-yard and put the helm alee; for till then the helm must be kept aweather and the yards full.

When the ship rides leeward tide, and the wind increases, care should be taken to give her more cable in time, otherwise the anchor may start, and probably it will be troublesome to get her brought up again; and this care is the more necessary when the ship rides in the hause of another ship. Previous to giving a long service it is usual to take a weather-bit, that is, a turn of the cable over the windlass end, so that in veering away the ship will be under command. The service ought to be greased, which will prevent its chafing in the hause.

If the gale continues to increase, the topmasts should be struck in time; but the fore-yard should seldom, if ever, be lowered down, that in case of parting the foresail may be ready to be set. At such times there should be more on deck than the common anchor-watch, that no accident may happen from inattention or falling asleep.

In a tide-way a second anchor should never be let go but when absolutely necessary; for a ship will sometimes ride easier and safer, especially if the sea runs high, with a very long scope of cable and one anchor, than with less length and two cables; however, it is advisable, as a preventive, when ships have not room to drive, and the night is dark, to let fall a second anchor under foot, with a range of cable along the deck. If this is not thought necessary to be done, the deep-sea lead should be thrown overboard, and the line frequently handed by the watch, that they may be assured she rides fast.

If at any time the anchor-watch, presuming on their own knowledge, should wind the ship, or suffer her to break her sheer without calling the mate, he should immediately, or the very first opportunity, oblige the crew to heave the anchor in sight; which will prevent the commission of the like fault again; for, besides the share of trouble the watch will have, the rest of the crew will blame them for neglecting their duty.

Prudent mates seldom lie a week in a road-stead without heaving their anchor in sight; even though they have not the least suspicion of its being foul. There are other reasons why the anchor should be looked at: sometimes the cable receives damage by sweeping wrecks or anchors that have been lost, or from rocks or stones; and it is often necessary to trip the anchor, in order to take a clearer birth, which should be done as often as any ship brings up too near.

SHIP-BUILDING may be defined, the manner of constructing ships, or the work itself, as distinguished from naval architecture, which may be considered as the theory or art of delineating ships on a plane.

Art of delineating ships on a plane.

All edifices, whether civil or military, are known to be erected in consequence of certain established plans, which have been previously altered or improved till they have arrived at their desired point of perfection. The construction of ships appears also to require at least as much correctness and precision as the buildings which are founded upon terra firma; it is therefore absolutely necessary that the mechanical skill of the shipwright should be assisted by plans and sections, which have been drawn with all possible exactness, examined by proper calculations, and submitted to the most accurate scrutiny.

Naval architecture may be distinguished

into three principal parts. 1. To give the ship such an exterior form as may be most suitable to the service for which she is designed. 2. To give the various pieces of a ship their proper figure; to assemble and unite them into a firm compact frame, so that by their combination and disposition they may form a solid fabric, sufficient to answer all the purposes for which it is intended. And, 3. To provide convenient accommodations for the officers and crew, as well as suitable apartments for the cargo, furniture, provisions, artillery, and ammunition.

The exterior figure of a ship may be divided into the bottom and upper works. The bottom, or quick-work, contains what is termed the hold, and which is under water when the ship is laden. The upper works, called also the dead-work, comprehend that part which is usually above the water when the ship is laden. The figure of the bottom is therefore determined by the qualities which are necessary for the vessel, and conformable to the service for which she is proposed.

The limits of our design will not admit of a minute description and enumeration of all the pieces of timber which enter into the construction of a ship, nor of a particular description of their assemblage and union, or the manner in which they reciprocally contribute to the solidity of those floating citadels.

It is usual among shipwrights to delineate three several draughts. 1. The whole length of the ship is represented according to a side view, perpendicular to the keel, and is termed the plane of elevation, or sheer draught. Plate II. fig. 10, 11, the ship is exhibited according to an end view, and stripped of her planks, so as to present the outlines of the principal timbers; and this is properly termed the plane of projection, or the vertical plane of the timbers (fig. 12), because it shows the projection of their frames relatively to each other. 3. It is not sufficient to have the vertical curves of the bottom in different places, for a distinct idea of the horizontal curves is also equally necessary and useful; this is obtained by means of water-lines, traced upon what is called the horizontal plane (fig. 11). In this draught the curves of the transoms, called the round-aft, are also marked, and sometimes the breadth and thickness of the timbers.

The plane of elevation (fig. 10), determines the length and depth of the keel; the difference of the draughts of water; the length and projection, or rake, of the stem and stern-post; the position of the midship-frame upon the keel, together with that of the principal frames afore and abaft; the load-water line; the wales; the dimensions and situations of the gun-ports; the projection of the rails of the head and stern-gallery; with the stations of the masts and channels.

This draught, however, conveys no idea of the vertical curve of the ribs or timbers; for as their projection will be only represented in a plane elevated upon the length of the keel, they will appear in this direction no otherwise than as straight lines. To perceive these curves accurately, they must be regarded in another point of view; which will represent their projection upon a vertical plane, supposed to cut the keel at right angles in the place where the ship is broadest. For, as all ships are broadest near the middle of their length than towards the extremities, it is evident that the timbers are more extended in proportion. The most capacious of these represents what is called the midship frame; and upon the area of this frame is delineated the projection of all the others.

Thus the plane of projection limits the different breadths of a ship in various points of her length, and exhibits the outline of the timbers respectively to each other as they are erected upon the keel. Accordingly, this draught ought to present a variety of sections of the ship in different places of her length, and always perpendicular to the surface of the water; so that the eye of the observer, when placed in what may be properly termed the axis of the ship, may perceive the several sections at one glance; that is to say, when looking full on the stem from before the ship, he shall discover the fore-timbers; and when looking from behind, directly to the stern, he shall perceive the form of the after-timbers.

To form a just idea of this plane, therefore, we ought to suppose a ship resting upon the stocks, in the same position as when afloat upon the water. Thus a variety of black vertical lines may be drawn at equal distances upon the bottom, which is white, to form different outlines of the ship corresponding to the timbers within. It is to be observed, that the fashion of the inferior timbers must conform to the figure of the midship frame, which is placed in the fullest part of the ship; and as the planes of all the other timbers diminish in a certain progression as they approach the stem and stern, they are properly delineated on the plane of the midship-frame, which also represents the depth of the keel and length of the midship-beam.

As the two sides of a ship ought to be exactly alike, it is judged sufficient to represent the sections of the fore-part of the ship on the left side, and those in the after-part on the right side, so as to perceive all the sections, as well afore as abaft, upon one plane. See the Plate, fig. 12.

However necessary it may be to understand precisely the vertical curves of the bottom, it is no less requisite to have a just idea of those which are horizontal.

The horizontal or floor-plane is that upon which the whole frame is erected, and will be more clearly understood by previously describing the water-lines and ribands of which it is composed.

When a ship floats upon the stream, it is evident that her upper works will be separated from the bottom by the surface of the water, which will accordingly describe an imaginary horizontal line upon the bottom from the stem to the stern-post.

The most elevated of those lines is termed the load water-line, which is supposed to be drawn by the surface of the water on the upper part of the bottom, when she is sufficiently laden for a sea-voyage. For if we suppose this surface a rule, and thereby describe a corresponding black line along the vessel's bottom, that line will be distinguished upon the bottom, which is white, and represent what is called the load water-line.

If the ship is lightened of any part of her lading, and preserves the same difference in her draught of water at the two ends; or, what is the same thing, if she is lightened so as to preserve the same equilibrium of the keel with regard to the surface of the water, it is evident that she will rise higher out of the water, so that the black line already described will be elevated above it; and another black line may be delineated upon the bottom, close to the surface of the water, which will exhibit a second water-line parallel to the first, but nearer the keel in proportion to the number of feet which the ship has risen.

Thus by lightening a ship gradually, and at the same time preserving the direction of her keel, or the angle which the keel makes with the surface of the water, a variety of water-lines may be drawn parallel to each other, and to the load water-line.

The ribands are likewise of great utility in ship-building; they are narrow and flexible planks placed on the bottom at different heights, so as to form a sort of mould for stationing the inferior timbers between the principal ones. They differ from the water-lines, inasmuch as the latter have only one curve, which is horizontal; whereas the ribands, besides their horizontal one, have a vertical curve. To convey a just idea of these curves, which cannot be represented on one draught at their full length without an oblique section of the ship's length, it will be necessary to have recourse to two planes; that of the elevation, which exhibits their vertical curve; and to the floor-plane, upon which the horizontal curve is expressed.

These different lines are extremely useful in exhibiting the various curves of a ship's bottom, that, as they are gradually diminished, their uniformity or irregularity may be discovered by the skilful artist.

The qualities required in a ship ought to determine the figure of the bottom. A ship of war, therefore, should be able to sail swiftly, and carry her lower tier of guns sufficiently out of the water; otherwise a small ship will have the advantage of a large one, inasmuch as the latter cannot open her lower battery in a fresh side-wind without being exposed to extreme danger by receiving a great quantity of water in at her ports between decks. A merchant-ship ought to contain a large cargo of merchant-goods, and be navigated with few hands; and both should be able to carry sail firmly, steer well, drive little to leeward, and sustain the shocks of the sea without being violently strained.

The first thing to be established in the draught of a ship, is her length; and as a ship of war, according to her rate, is furnished with a certain number of cannon, which are placed in battery on her decks, it is necessary that a sufficient distance should be left between their ports to work the guns with facility; and particularly to leave space enough between the foremost guns and the stem, and between the aftmost gun and the stern-post on each side, on account of the arching or inward curve of the ship toward her extremities.

When the length of a ship is determined, it is usual to fix her breadth by the dimensions of the midship-beam. On this occasion the shipwrights, for the most part, are conducted by rules founded on their own observation; for, having remarked, that some vessels, which by repeated experience have been found to answer all the purposes of navigation, have a certain breadth in proportion to their length, they have inferred that it would be improper to depart from this proportion; but as other ships have been constructed with different breadths, which were equally perfect, a variety of different general rules have been adopted by these artists, who are accordingly divided in their opinions about the breadth which ought to be assigned to a ship relatively with her length, whilst each one produces reasons and experience in support of his own standard. Those who would diminish the breadth, allege: 1. That a narrow vessel meets with less resistance in passing through the water. 2dly. That by increasing the length she will drive less to leeward. 3dly. That according to this principle, the water-lines will be more conveniently formed to divide the fluid. 4thly. That a long and narrow ship will require less sail to advance quickly; that her masts will be lower, and her rigging lighter; and, by consequence, the seamen less fatigued with managing the sails, &c. Those, on the contrary, who would enlarge the breadth, pretend, 1st. That this form is better fitted to preserve a good battery of guns. 2ndly. That there will be more room to work the guns conveniently. 3rdly. That by carrying more sail, the ship will be enabled to run faster; or, that this quality will at least overbalance the advantage which the others have of more easily dividing the fluid. 4thly. That being broader at the load water-line, or place where the surface of the water describes a line round the bottom, they will admit of being very narrow on the floor, particularly towards the extremities. And, 5thly. That a broad vessel will more readily rise upon the waves than a narrow one. From such opposite principles has resulted that variety of standards adopted by different shipwrights.

It has been remarked above, that a ship of war must carry her lower tier of cannon high enough above the water, otherwise a great ship which cannot open her lower battery, when sailing with a fresh side-wind, may be taken by a small one that can make use of her cannon.

A ship should be duly poised, so as not to dive or pitch heavily, but go smooth and easy through the water, rising to the waves when they run high, and the ship has reduced her sail to the storm; otherwise they will break aboard, and strain the decks or carry away the boats: the masts are likewise in great danger from the same cause.

A ship should sail well when large and before the wind, but chiefly close hauled, or with a side-wind, and her sails sharp-trimmed, and then not fall off to the leeward.

Now, the great difficulty lies in uniting so many different qualities in one ship, which seems to be nearly impossible; the whole art, therefore, consists in forming the body in such a manner that none of these qualities should be entirely destroyed, and in giving a preference to that which is chiefly required in the particular service for which the vessel is designed. We shall briefly show the possibility of uniting them all in one ship, that each of them may be easily discerned; when it happens otherwise, the fault must lie in the builder, who has not applied himself to study the fundamental rules and principles of his art.

To make a ship carry a good sail. A flat floor-timber, and somewhat long, or the lower futtock pretty round, a straight upper futtock, the top-timber to throw the breadth out aloft; at any rate, to carry her main breadth as high as the lower deck. Now, if the rigging is well adapted to such a body, and the upper works lightened as much as possible, so that they all concur to lower the centre of gravity, there will be no room to doubt of her carrying a good sail.

To make a ship steer well, and answer the helm quickly. If the fashion-pieces are well formed, the tuck, or spreading parts under the stern, carried pretty high, the midship-frame well forward, a considerable difference in the draught of water abaft more than afore, a great rake forward and none abaft, a snug quarter-deck and fore-castle; all these will make a ship steer well. A ship which sails well will certainly steer well.

To make a ship carry her guns well out of the water. A long floor-timber, and not of great rising; a very full midship-frame, and low tuck, with light upper works.

To make a ship go smoothly through the water without pitching hard. A long keel, a long floor, not to rise too high afore and abaft; but the area or space continued in the fore-body, according to the respective weights they are to carry; all these are necessary to make a ship go smoothly through the water.

To make a ship keep a good wind, and drive little to the leeward. A good length by the keel; not too broad, but pretty deep in the hold, which will occasion her to have a short floor-timber, and a great rising. As such a ship will meet with great resistance in the water going over the broadside, and little when going ahead, she will not fall much to the leeward.

Now, some builders imagine it is impossible to make a ship carry her guns well, bear a good sail, and be a prime sailer, because it would require a very full bottom to gain the first two qualities, whereas a sharp ship will answer better for the latter; but when it is considered that a full ship will carry a great deal more sail than a sharp one, a good artist may so form the body as to have all these three good qualities, and also steer well.

Without attempting to describe the pieces of which a ship is composed, and to explain the principal draughts used in the construction thereof, we observe that in vessels of war, the general dimensions are established by authority of officers appointed by the government to superintend the building of ships. In the merchant-service, the extreme breadth, length of the keel, depth in the hold, height between decks and in the waist, are agreed on by contract; and from these dimensions the shipwright is to form a draught suitable to the trade for which the ship is designed.

In projecting the draught of a vessel of war, the first article to be considered is her length. As all ships are much longer above than below, it is also necessary to distinguish the precise part of her height from which her length is taken: this is usually the lower gun deck, or the load water-line. It has been already observed, that water-lines are described longitudinally on a ship's bottom by the surface of the water in which she floats, and that the line which determines her depth under the water, is usually termed the load water-line. In this draught it will be particularly necessary to leave sufficient distance between the ports.

The next object is to establish the breadth by the midship-beam. Although there is great difference of opinion about proportioning the breadth to the length, yet it is most usual to conform to the dimensions of ships of the same rate. After the dimensions of the breadth and length are determined, the depth of the hold must be fixed, which is generally half the breadth; but the form of the body should be considered on this occasion; for a flat floor will require less depth in the hold than a sharp one. The distance between the decks must also be settled.

We may then proceed to fix the length of the keel, by which we shall be enabled to judge of the rake of the stem and stern-post. The rake is known to be the projection of the ship at the height of the stem and stern-post beyond the ends of the keel afore and abaft, or the angle by which the length is increased as the fabric rises. To these we may also add the height of the stem and wing-transom.

After these dimensions are settled, the timbers may be considered which form the sides of the ship. A frame of timbers, which appears to be one continued piece, is composed of one floor-timber, whose arms branch outward to both sides of the ship; two or three futtocks, and a top-timber. The futtocks are connected to the upper arms of the floor-timbers on each side of the ship, and serve to prolong the timber in a vertical direction; and the top-timbers are placed at the upper part of the futtocks for the same purpose; all these being united, and secured by cross-bars, or a circular inclosure, which is called a frame of timbers. And as a ship is much broader at the middle than at the extremities, the arms of the floor-timber will form a very obtuse angle at the extreme breadth; but this angle decreases in proportion to the distance of the timbers from the midship-frame, so that the foremost and aftmost ones will form a very acute angle. Floor-timbers of the latter sort are usually called crutches.

Shipwrights differ extremely in determining the station of the midship-frame; some placing it at the middle of the ship's length, others further forward. They who place it before the middle allege, that if a ship is full forwards, she will meet with no resistance after she has opened a column of water; and that the water so displaced will easily unite abaft, and by that means force the ship forward; besides having more power on the rudder, in proportion to its distance from the centre of gravity; this also comes nearer the form of fishes, which should seem the most advantageous for dividing the fluid.

When the rising of the midship floor-timber is decided, we may then proceed to describe the rising line of the floor, on the stern-post abaft, and on the stem afore.

The height of the lower-deck is the next thing to be considered: it is determined in the middle by the depth of the hold; and some builders make it no higher than the stem; but they raise it abaft as much above its height in the middle as the load water-mark, or draught of water abaft, exceeds that afore. With regard to the height between decks, it is altogether arbitrary, and must be determined by the rate of the ship and the service she is designed for.

It is also necessary to remember the sheer of the wales, and to give them a proper hanging; because the beauty and stateliness of a ship greatly depend upon their figure and curve, which, if properly drawn, will make her appear airy and graceful on the water.

We come now to consider the upper works, and all that is above water, called the dead-work: and here the ship must be narrower, so that all the weight lying above the load water-line, will thereby be brought nearer the middle of the breadth, and of course the ship will be less strained by the working of her guns, &c.

But although some advantages are acquired by diminishing the breadth, above water, we must be careful not to narrow her too much; as there must be sufficient room left on the upper deck for the guns to recoil. The security of the masts should likewise be remembered, which requires sufficient breadth to spread the shrouds. A deficiency of this sort may indeed be in some measure supplied by enlarging the breadth of the channels.

We come to explain the sheer-draught, or plane of elevation, of a sixty-gun ship.

AA, fig. 10. is the keel, whose upper edge is prolonged by the dotted line *p q*; upon the extremities of which are erected perpendiculars which determine the height of the wing-transom K, and the length of the gun deck KC. AB, the stern-post. AC, the stem. DD, the quarter gallery with its windows. EF, the quarter-pieces, which limit the stern on each side. F, the taffarel, or upper piece of the stern. FG, profile of the stern; with its galleries. H, the gun-ports. I, the channels, with their dead-eyes and chain-plates. K, the wing-transom. KG, the counter. LB, the deck-transom. MNO, the first, second, and third transoms, of which O *k* is the third or lowest. *m* OLP, the direction of the fashion-piece, having its breadth canted aft towards the stern. QR, the main skeeds, for hoisting in the boats clear of the ship's side. LQZ, the main wale, with its sheer afore and abaft. DRX, the channel-wales, parallel to the main-wale. SUS. the sheer rail parallel to the wales. T *t*, the rudder. A *t* F, the rake of the stern. VWV, the waist rail. P *i i*, the drift rails abaft; and *ia*, the drift rails forward. TUC, the water-line. XX, the rails of the head. Y, the knee of the head, or cutwater. ZZ, the cheeks of the head. *a a*, the cat head. M⊕C, The rising line of the floor. *k u* C, the cutting down line, which limits the thickness of all the floor-timbers, and likewise the height of the dead wood afore and abaft. ⊕ *u* UW, the midship-frame. *a, b, c, d, e, f, g, h*, the frames or timbers in the fore body of the ship, that is, before the midship-frame. 1, 2, 3, 4, 5, 6, 7, 8, 9, the timbers in the after-body, or which are erected abaft the midship-frame.

As the eye of a spectator is supposed in this projection to view the ship's side in a line perpendicular to the plane of elevation, it is evident that the convexity will vanish, like that of a cylinder or globe, when viewed at a great distance; and that the frames will consequently be represented by straight lines, except the fashion-piece abaft and the knuckle-timber forward.

It has been already observed, that the plane of projection may be defined a vertical delineation of the curves of the timbers upon the plane of the midship-frame, which is perpendicular to that of the elevation. It is necessary to observe here, that the various methods by which these curves are described, are equally mechanical and arbitrary. In the latter sense, they are calculated to make a ship fuller or narrower, according to the service for which she is designed; and in the former they are drawn according to those rules which the artist has been implicitly taught to follow, or which his fancy or judgment has esteemed the most accurate and convenient. They are generally composed of several arches of a circle, reconciled together by moulds framed for that purpose. The radii of those arches, therefore, are of different lengths, according to the breadth of the ship in the place where such arches are swept; and they are expressed on the plane of projection either by horizontal or perpendicular lines; the radii of the breadth-sweeps being always in the former, and the radii of the floor-sweeps in the latter direction. These two arches are joined by a third, which coincides with both without intersecting either. The curve of the top-timber is either formed by a mould which corresponds to the arch of the breadth-sweep, or by another sweep, whose centre and radius are without the plane of projection. The breadth of the ship at every top-timber, is limited by a horizontal line drawn on the floor-plane, called the half-breadth of the top timbers. The extreme breadth is also determined by another horizontal line on the floor-plane; and the lines of half-breadth are thus mutually transferable from the projection and floor-planes to each other.

The necessary data by which the curves of the timbers are delineated, then, are the perpendicular height from the keel; the main or principal breadth; and the top breadth; for as a ship is much broader near the middle of her length than towards the end, so she is broader in the middle of her height than above and below; and this latter difference of breadth is continued throughout every point of her length. The main breadth of each frame of timbers is therefore the ship's breadth nearly in the middle of her height in that part, and the top-timber breadth is the line of her breadth near the upper ends of each timber. It has been already observed, that as both sides of a ship are alike, the artificers only draw one side, from which both sides of the ship are built: therefore the timbers abaft the midship-frame are exhibited on one side of the plane of projection, and the timbers before it on the other.

Plane of projection.

Fig. 12. A, the keel. BC, the line which expresses the upper edge of the keel, from which the height of each timber and height of its different breadths are measured. BD, and CE, perpendiculars raised on the line BC, to limit the ship's extreme breadth and height amid-ships; or, in other words, to limit the breadth and height of the midship-frame. AF, a perpendicular erected from the middle of the keel to bisect the line of the ship's breadth in two equal parts. F 9, the half-breadth line of the aftmost top-timber; being the uppermost horizontal line in this figure.

Note. The seven lines parallel to and immediately under this, on the right side of the line AF, are all top-timber half-breadths, abaft the midship-frame; the lowest of which coincides with the horizontal line DE.

The parallel horizontal lines nearly opposite to these, on the left side of the line AF, represent the top-timber half-breadths in the fore body, or the half-breadths of the top-timbers before the midship-frame.

G, H, I, Q, R, S, T, the radii of the breadth-sweeps abaft the midship-frame; those of the breadth sweeps in the fore-body, or before the midship-frame, are directly opposite on the right side.

⊕, A, show the midship frame, from the extreme breadth downwards.

1, 2, 3, 4, 5, 6, 7, 8, 9, the outlines of the timbers abaft the midship-frame, in different parts of the height: *a, b, c, d, e, f, g, h*, the outlines of the timbers before the midship-frame, in different parts of their height, *h* being the foremost or knuckle-timber. K *i*, the wing-transom, whose ends rest upon the fashion-piece. L, the deck-transom, parallel to and under the wing-transom. MNO, the lower transoms, of which O *k* is the third and lowest. *m k* P, the dotted line, which expresses the figure of the fashion-piece without being canted aft. P, the upper part, or top-timber of the fashion-piece. *n, o, p, q, r, s*, the radii of the floor-sweeps, abaft the midship-frame; those before the midship-frame are on the opposite side of the line AF, to which they are all parallel.

1st R*d*, 2d R*d*, 3d R*d*, 4th R*d*, the diagonal ribands abaft the midship; *t, u, x, y*, the same ribands expressed in the fore-body.

It has been remarked above, that the horizontal plane is composed of water-lines and ribands; it also contains the main and top-timber-breadth lines, or longitudinal lines by which the main-breadth and top-timber-breadth are limited in every point of the ship's length. The horizontal curve of the transoms and harpins are also represented therein; together with the planes of the principal timbers, the cant of the fashion-piece, the length of the rake afore and abaft, the projection of the cat heads, and the curve of the upper rail of the head, to which the curves of the lower ones are usually parallel.

Horizontal Plane.

BAC, Fig. 11, the line of the ship's length, passing through the middle of the stem and stern-post. B, the upper end of the stern-post. C, the upper end of the stem. BF, the length of the rake abaft. DWX, the top-timber-breadth line, or the line which limits the breadth of each top-timber.

DF, the breadth of the aftmost timber at the taffarel. BK, the wing-transom. BLP, the horizontal curve of the deck-transom. MM, the horizontal curve, or round-aft, of the first transom. MN, the horizontal curve of the second transom: it is prolonged into a water-line, N 8 7. *k* O, the horizontal curve of the third transom, which is also prolonged into another water-line, O, *n*, U, *n*, Q. *m* OP, the plane of the fashion-piece, as canted aft. ⊕ WU, the plane of the midship-frame. *a, b, c, d, e, f, h,* the planes of the timbers before the midship-frame. 1, 2, 3, 4, 5, 6, 7, 8, 9, the plane of the timbers abaft the midship-frame. XX, the figure of the upper rail of the head. CY, the projection of the knee of the head.

The third horizontal riband is marked on the plate. *a, a,* the projection of the cat-head.

Thus we have endeavoured briefly to explain the nature and uses of the principal draughts used in the construction of a ship, which reciprocally correspond with each other in the dimensions of length, breadth, and depth. Thus the plane of elevation is exactly of the same length with the horizontal or floor-plane. The several breadths of the timbers in the floor-plane, and that of the projection, are mutually transferable; and the real height of the timbers in the projection exactly conforms to their height in the elevation. Thus, let it be required to transfer the height of the wing-transom from the elevation to the projection:

Extend the compasses from the point K, in the elevation, down to the dotted line prolonged from the upper edge of the keel, and setting the other foot in the point *p*, then shall the line K *p* be the perpendicular height in the wing-transom: transfer this from the middle of the line BAC, in the projection, to the point K in the perpendicular AF, then will AK be the height of the wing-transom in the plane of projection: and thus the height of all the transoms may be laid from the former upon the latter.

Again: Let it be required to transfer the main-breadth of the midship-frame from the projection to the horizontal plane: Set one foot of the compasses in the point ⊕ on the perpendicular CE, and extend the other along the main-breadth sweep ⊕ G, till it touches the perpendicular AP parallel to CE: lay this distance upon the horizontal plane from the point *u* in the line of the ship's length, BAC, along the plane of the midship-frame to the point ⊕; so shall the line ⊕ WU be the breadth of the midship-frame on the horizontal plane.

Thus also the top-timber-breadth, or the distance of each top-timber from the middle of the ship's breadth, may be in the same manner transferred, by extending the compasses from the line BAC, in the horizontal plane, to the top-timber-breadth line upon any particular timber, as 1, 2, 3, &c. which will give its proper dimensions thereon.

In the same manner the breadths of all the timbers may be laid from the projection to the horizontal plane, and, vice versa, from that to the projection. Thus the height of each timber may also be transferred from the elevation to the projection, &c.

The principal utility of these draughts, therefore, is to exhibit the various curves of the ship's body, and of the pieces of which it is framed, in different points of view, which are either transverse or longitudinal, and will accordingly present them in very different directions. Thus the horizontal curves of the transoms and water-lines are represented on the floor-plane, all of which are nearly straight lines in the elevation and projection; and thus the vertical curves of the timbers are all exhibited on the projection, although they appear as straight lines in the elevation and floor-plane.

Of constructing ships.

The pieces by which this complicated machine, a ship, is framed, are joined together in various places, by scarfing, rabitting, tenanting, and scoring.

During the construction of a ship, she is supported in the dock, or upon a wharf, by a number of solid blocks of timber placed at equal distance from, and parallel to, each other. She is then said to be on the stocks.

The first piece of timber laid upon the blocks is generally the keel: we say generally, because of late, a different method has been adopted in some of the royal dock-yards, by beginning with the floor timbers; the artists having found that the keel is often apt to rot during the long period of building a large ship of war. The pieces of the keel are scarfed together, and bolted, forming one entire piece, AA, which constitutes the length of the vessel below. At one extremity of the keel is erected the stem. It is a strong piece of timber incurvated nearly into a circular arch, or, according to the technical term, compassing, so as to project outwards at the upper-end, forming what is called the rake forward. In small vessels this is framed of one piece; but in large ships it is composed of several pieces scarfed and bolted together. At the other extremity of the keel is elevated the stern-post, which is always of one entire straight piece. The heel of it is let into a mortoise in the keel, and having its upper end to hang outwards, making an obtuse angle with the keel, like that of the stem: this projection is called the rake abaft. The stern-post, which ought to support the stern, contains the iron-work, or hinges of the rudder, which are called googings, and unites the lower part of the ship's sides abaft. See the connection of those pieces in the elevation, fig. 10.

Towards the upper-end of the stern-post, and at right angles with its length, is fixed the middle of the wing-transom, where it is firmly bolted. Under this is placed another piece parallel thereto, and called the deck-transom, upon which the after-end of the lower deck is supported. Parallel to the deck-transom, and at a proper distance under it, another piece is fixed to the stern-post called the first-transom; all of which serve to connect the stern-post to the fashion-pieces. Two more transoms, called second and third, are also placed under these, being likewise attached to the fashion-pieces, into which the extremities of all the transoms are let. The fashion-pieces are formed like the other timbers of the ship, and have their heels resting on the upper part of the kelson, at the after extremity of the floor-ribands.

All these pieces, viz. the transoms, the fashion-pieces, and their top-timbers being strongly united into one frame, are elevated upon the stern-post; and the whole forms the structure of the stern, upon which the galleries and windows, with their ornaments, are afterwards built.

The stem and stern-post being thus elevated upon the keel, to which they are securely connected by knees and arched pieces of timber bolted to both; and the keel being raised at its two extremities by pieces of dead wood, the midship floor-timber is placed across the keel, whereto it is bolted through the middle. The floor-timbers before and abaft the midship frame are then stationed in their proper places upon the keel; after which the kelson, which, like the keel, is composed of several pieces scarfed together, is fixed across the middle of the floor-timbers, to which it is attached by bolts driven through the keel, and clinched on the upper part of the kelson. The futtocks are then raised upon the floor-timbers, and the hawse-pieces erected upon the cant timbers in the fore part of the ship. The top-timbers on each side are next attached to the head of the futtocks, as already explained. The frames of the principal timbers being thus completed, are supported by ribands.

The ribs of the ship being now stationed, they proceed to fix on the planks, of which the wales are the principal, being much thicker and stronger than the rest. The harpins, which may be considered as a continuation of the wales at their fore-ends, are fixed across the hawse-pieces, and surround the fore part of the ship. The planks that inclose the ship's sides are then brought about the timbers; and the clamps, which are of equal thickness with the wales, fixed opposite to the wales within the ship: these are used to support the ends of the beams, and accordingly stretch from one end of the ship to the other. The thick-stuff, or strong planks of the bottom within-board, are then placed opposite to the several scarfs of the timbers, to reinforce them throughout the ship's length. The planks employed to line the ship, called the ceiling, or foot-waling, is next fixed in the intervals between the thick stuff of the hold. The beams are afterwards laid across the ship to support the decks, and are connected to the side by lodging and hanging knees.

The cable bits being next erected, the carlings, and ledges, are disposed between the beams to strengthen the deck. The water-ways are then laid on the ends of the beams throughout the ship's length, and the sprikett-ing fixed close above them. The upper deck is then planked, and the string placed under the gunnel or plansheer in the waist.

They proceed next to plank the quarter-deck and fore-castle, and to fix the partners of the masts and capsterns with the coamings of the hatches. The breast-hooks are then bolted across the stem and bow within-board; the step of the fore-mast placed on the kelson; and the riders fayed on the inside of the timbers, to reinforce the sides in different places of the ship's length. The pointers, if any, are afterwards fixed across the hold diagonally to support the beams; and the crotchets stationed in the after-hold to unite the half-timbers. The steps of the main-mast and capsterns are next placed; the planks of the lower-decks and orlop laid; the navel-hoods fayed on the hawse-holes; and the knee of the head, or cutwater, connected to the stem. The figure of the head is then erected, and the trail-board and cheeks are fixed on the sides of the knee.

The taffarel and quarter-pieces, which terminate the ship abaft, the former above and the latter on each side, are then disposed; and the stern and quarter galleries framed and supported by their brackets. The pumps, with their well, are next fixed in the hold; the limber-boards laid on each side of the kelson; and the garboard strake fixed on the ship's bottom next to the keel without.

The hull being thus fabricated, they proceed to separate the apartments by bulkheads, or partitions; to frame the portlids; to fix the cat-heads and chess-trees; to form the hatchways and scuttles, and fit them with proper covers or gratings. They next fix the ladders whereby to mount or descend the different hatchways; and build the manger on the lower deck, to carry off the water that runs in at the hawse-holes when the ship rides at anchor in a sea. The bread-room and magazines are then lined; and the gunnel, rails, and gangways, fixed on the upper part of the ship. The cleats, kevels, and rand ranges, by which the ropes are fastened, are afterwards bolted or nailed to the sides in different places.

The rudder, being fitted with its irons, is next hung to the stern-post; and the tiller, or bar, by which it is managed, let into a mortoise at its upper-end. The scuppers, or leaden tubes, that carry the water off from the decks, are then placed in holes cut through the ship's sides; and the standards bolted to the beams and sides above the decks to which they belong. The poop-lanthorns are last fixed upon their cranes over the stern; and the bilge-ways, or cradles, placed under the bottom, to conduct the ship steadily into the water whilst launching.

Stowing and trimming of ships, the method of disposing of the cargo in a proper and judicious manner in the hold of a ship. A ship's sailing, steering, and wearing, and being lively and comparatively easy at sea in a storm, depend greatly on the cargo, ballast, or other materials, being properly stowed, according to their weight and bulk, and the proportional dimensions of the built of the ship, which may be made too crank or too stiff to pass on the ocean with safety. These things render this branch of knowledge of such consequence, that rules for it ought to be endeavoured after, if but to prevent, as much as possible, the danger of a ship oversetting at sea, or being so laboursome as to roll away her masts, &c. by being improperly stowed, which is often the case.

When a ship is new, it is prudent to consult the builder, who may be supposed best acquainted with a ship of his own planning, and most likely to judge what her properties will be, to judge how the cargo of materials, according to the nature of them, ought to be disposed of to advantage, so as to put her in the best sailing trim; and at every favourable opportunity afterwards it will be proper to endeavour to find out her best trim by experiment.

Ships must differ in their form and proportional dimensions; and to make them answer their different purposes, they will require different management in the stowage, which ought not to be left to mere chance, or done at random, as goods or materials happen to come to hand, which is too often the cause that such improper stowage makes ships unfit for sea: therefore the stowage should be considered, planned, and contrived, according to the built and properties of the ship, which if they are not known should be inquired after. If she is narrow and high-built in proportion, so that she will not shift herself without a great weight in the hold, it is a certain sign such a ship will require a great part of heavy goods, ballast, or materials, laid low in the hold, to make her stiff enough to bear sufficient sail without being in danger of oversetting. But if a ship is built broad and low in proportion, so that she is stiff and will support herself without any weight in the hold, such a ship will require heavy goods, ballast, or materials, stowed higher up, to prevent her from being too stiff and laboursome at sea, so as to endanger her masts being rolled away, and the hull worked loose and made leaky.

In order to help a ship's sailing, that she should be lively and easy in her pitching and ascending motions, it should be contrived by the stowage, that the principal and weightiest part of the cargo or materials should lie as near the main body of the ship, and as far from the extreme ends, fore and aft, as things will admit of. For it should be considered, that the roomy part of our ships lengthwise, forms a sweep or curve near four times as long as they are broad; therefore those roomy parts at and above the water's edge, which are made by a full harping and a broad transom to support the ship steady and keep her from plunging into the sea, and also by the entrance and run of the ship having little or no bearing body under for the pressure of the water to support them, of course should not be stowed with heavy goods or materials, but all the necessary vacancies, broken stowage, or light goods, should be at these extreme ends fore and aft; and in proportion as they are kept lighter by the stowage, the ship will be more lively to fall and rise easy in great seas; and this will contribute greatly to her working and sailing, and to prevent her from straining and hogging; for which reason it is a wrong practice to leave such a large vacancy in the main hatchway as is usual, to coil and work the cables, which ought to be in the fore or aft hatchway, that the principal weight may be more easily stowed in the main body of the ship, above the flattest and lowest floorings, where the pressure of the water acts the more to support it. See NAVIGATION.

SHIPS, *masts of*. The mast of a ship is a long round piece of timber, elevated perpendicularly upon the keel of a ship, to which are attached the yards, the sails, and the rigging. A mast, with regard to its length, is either formed of one single piece, which is called a pole-mast, or composed of several pieces joined together, each of which retains the name of mast separately. The lowest of these is accordingly named the lower-mast; the next in height is the top-mast, which is erected at the head of the former; and the highest is the top-gallant mast, which is prolonged from the upper end of the top-mast. Thus the two last are no other than a continuation of the first upwards.

The lower-mast is fixed in the ship; the foot, or heel of it, rests on a block of timber called the step, which is fixed upon the kelson, and the top-mast is attached to the head of it by the cap and the trestle-trees. The latter of these are two strong bars of timber, supported by two prominences, which are as shoulders on the opposite sides of the mast, a little under its upper end: athwart these bars are fixed the cross-trees, upon which the frame of the top is supported. Between the lower-mast-head, and the foremost of the cross-trees, a square space remains vacant, the sides of which are bounded by the two trestle-trees. Perpendicularly above this is the foremost hole in the cap, whose after-hole is solidly fixed on the head of the lower-mast. The top-mast is erected by a tackle, whose effort is communicated from the head of the lower-mast to the foot of the top-mast; and the upper end of the latter is accordingly guided into and conveyed up through the holes between the trestle-trees and the cap.

Besides the parts already mentioned in the construction of masts, with respect to their length, the lower-masts of the largest ships are composed of several pieces united into one body. As these are generally the most substantial parts of various trees, a mast formed by this assemblage, is justly esteemed much stronger than one consisting of any single trunk, whose internal solidity may be very uncertain.

The whole is secured by several strong hoops of iron, driven on the outside of the mast, where they remain at proper distances.

Figs. 1, 2, and 3, Plate Masts, &c. represent one of Mr. George Smart's patent hollow masts. It is principally composed of four small beams ABDE, figs. 1 and 2, which are each quarters of one small tree; these are held at the proper distance apart by cross bars FF mortised into them. The spaces between these four beams are filled up by thick planks GG, which have grooves cut across them to receive one-half of the bars FF as shewn in fig. 3, and the whole is bound together by hoops HH. By this means a truss is formed in every direction; for in every strain, before the mast can give way, the beams and planks on the side nearest the strain must compress, and those on the opposite side must be torn asunder lengthwise.

There are several other methods of constructing these masts, as eight planks doweled together at the edges, or four planks tabled into each other with oak wedges at the end of the tables, to prevent the end wood from cutting into each other.

Masts on these principles can be made at one half the expence of the common ones, and of the same strength without any increase of the weight.

Figs. 4 and 5, represent a contrivance included in Mr. Smart's patent for masts, by which temporary yards for ships can be made when at sea, and of such spars as can conveniently be carried on board a ship. They are formed of two small spars, each half the length of the yard, which are sawn down lengthwise in two directions, so as to cut them into four branches, but left joined together at one end, A fig. 4: that end is then hooped so as to prevent splitting; the four pieces DEF, &c. are opened out as in the figure, and blocks of wood put in between them at GHIK to keep them apart; the two spars thus opened are joined together to make one yard at the block K formed of four pieces, one of which is shewn in fig. 5. It has a groove in it to receive the ends of one of the bars DEF in each spar and connect them; it has some small pieces put across in the angle of the groove, which are let into the ends of the pieces DEF, so that when they are kept in their places, by a broad hoop L, they cannot be drawn apart endways; the four pieces composing the block K are laid together, and put in between the bars, leaving a space between them to put in

2

wedges which are drove in until the pieces fig. 5 are shoved out so as to fill the hoop and hold it all firmly.

Small yards may be made from one spar without joining; in that case the four pieces are left connected at each end, and the piece K is a plain block like the rest.

Yards on this construction can be considerably increased in their strength (if found too weak) by putting in larger blocks; which increases their diameter, and throws the four bars farther from each other without increasing their weight more than the extra weight of the blocks.

The principal articles to be considered in equipping a ship with masts are, 1st, the number; 2d, their situation in the vessel; and, 3d, their height above the water.

The masts being used to extend the sails by means of their yards, it is evident, that if their number was multiplied beyond what is necessary, the yards must be extremely short, that they may not entangle each other in working the ship, and by consequence their sails will be very narrow, and receive a small portion of wind. If, on the contrary, there is not a sufficient number of masts in the vessel, the yards will be too large and heavy, so as not to be managed without difficulty. There is a mean between these extremes, which experience and the general practice of the sea have determined; by which it appears, that in large ships every advantage of sailing is retained by three masts and a bowsprit.

The most advantageous position of the masts is undoubtedly that from whence there results an equilibrium between the resistance of the water on the body of the ship on one part, and of the direction of their effort on the other. By every other position this equilibrium is destroyed, and the greatest effort of the masts will operate to turn the ship horizontally about its direction; a circumstance which retards her velocity. It is counterbalanced indeed by the helm; but the same inconvenience still continues; for the force of the wind, having the resistance of the helm to overcome, is not entirely employed to push the vessel forward. The axis of the resistance of the water should then be previously determined, to discover the place of the main-mast, in order to suspend the efforts of the water equally, and place the other masts so that their particular direction will coincide with that of the main-mast. The whole of this would be capable of a solution if the figure of the vessel was regular, because the point, about which the resistance of the water would be in equilibrio, might be discovered by calculation.

The exact height of the masts, in proportion to the form and size of the ship, remains yet a problem to be determined. The more the masts are elevated above the centre of gravity, the greater will be the surface of sail which they are enabled to present to the wind; so far an additional height seems to have been advantageous. But this advantage is diminished by the circular movement of the mast, which operates to make the vessel stoop to its effort; and this inclination is increased in proportion to the additional height of the mast, an inconvenience which it is necessary to guard against. Thus what is gained upon one hand is lost upon the other. To reconcile these differences, it is certain, that the height of the mast ought to be determined by the inclination of the vessel, and that the point of her greatest inclination should be the term of this height above the centre of gravity.

In order to secure the masts, and counterbalance the strain they receive from the effort of the sails impressed by the wind, and the agitation of the ship at sea, they are sustained by several strong ropes, extended from their upper ends to the outside of the vessel, called shrouds. These are further supported by other ropes, stretched from their heads towards the fore-part of the vessel.

The mast, which is placed at the middle of the ship's length, is called the main-mast; that which is placed in the forepart, the foremast; and that which is towards the stern, is termed the mizen-mast.

SHISTUS. See SCHISTUS, and ROCKS *primitive*.

SHIVERS, or SHEEVERS, in the sea-language, names given to the little rollers or round wheels of pulleys. See PULLEY.

SHOE, a covering for the foot, usually made of leather, by the company of cordwainers.

SHOES, *horse*. See FARRIERY.

SHOE, *for an anchor*, in a ship, the place for the anchor to rest, and fitted to receive the stock, &c. so as to prevent the sheets, tacks, and other running-rigging, from galling, or being entangled with the flooks.

SHOOTING, in the military art. See ARTILLERY, GUNNERY, and PROJECTILES.

SHOOTING, in sportsmanship, the killing of game by the gun, with or without the help of dogs.

The first thing which the sportsman ought to attend to is the choice of his fowling-piece. Conveniency requires that the barrel should be as light as possible, at the same time it ought to possess that degree of strength which will make it not liable to burst. In a former article (GUN-SMITHERY, vol. i. p. 890) it was stated that very little was gained by extending the length of the barrel. It ought, however, to bear some proportion to the bore, and be of sufficient length to permit all the powder to inflame. The usual length is now from 26 to 30 inches.

It may appear as an objection to this, that a duck-gun which is five or six feet long kills at a greater distance than a fowling-piece; but this is not owing to its length, but to its greater weight and thickness, which give it such additional strength, that the shot may be increased, and the charge of powder doubled, trebled, and even quadrupled. More, indeed, will depend on the goodness of the powder, and using a proper charge (which must be learned by trying the gun at a mark), than on the length of the barrel.

The patent milled shot is now very generally used, and is reckoned superior to any other. The size of the shot must vary according to the particular species of game which is the object of the sportsman's pursuit, as well as be adapted to the season. In the first month of partridge-shooting, No. 4 is most proper.

As hares also sit closer, and are thinly covered with fur, at this season, they may easily be killed with this shot at 30 or 35 paces. No. 5, is proper for shooting quails; and No. 3, for snipes. About the beginning of October, when the partridges are stronger, and pheasant-shooting commences, No. 3 may be used.

In loading a piece, the powder ought to be slightly rammed down by only pressing the ramrod two or three times on the wadding, and not by drawing up the ramrod and then returning it into the barrel with a jerk of the arm several times. The shot ought to be rammed down with some force, since it is from the shot being loose in the gun, and a space being consequently left between it and the powder, that accidents most frequently happen by the bursting of guns. A sportsman ought never to carry his gun under his arm with the muzzle inclined downwards, for this practice loosens the wadding and charge too much.

Immediately after the piece is fired it ought to be re-loaded; for, while the barrel is still warm, there is no danger of any moisture lodging in it to hinder the powder from falling to the bottom. As it is found that the coldness of the barrel, and perhaps the moisture condensed in it, diminish the force of the powder in the first shot, it is proper to fire off a little powder before the piece is loaded. Some prime before loading, but this is not proper unless the touch-hole is very large. After every discharge the touch-hole ought to be pricked, or a small feather may be inserted to clear away any humidity or foulness that has been contracted.

The sportsman having loaded his piece, must next prepare to fire. For this purpose he ought to place his hand near the entrance of the ramrod, and at the same time grasp the barrel firmly. The muzzle should be a little elevated, for it is more usual to shoot low than high. This direction ought particularly to be attended to when the object is a little distant; because shot as well as ball only moves a certain distance point-blank, when it begins to describe the curve of the parabola.

Practice soon teaches the sportsman the proper distance at which he should shoot. The distance at which he ought infallibly to kill any kind of game with patent shot, provided the aim is well taken, is from 25 to 35 paces for the footed, and from 40 to 45 paces for the winged game. Beyond this distance even to 50 or 55 paces, both partridges and hares are sometimes killed; but in general the hares are only slightly wounded, and carry away the shot; and the partridges at that distance present so small a surface, that they frequently escape untouched between the spaces of the circle. Yet it does not follow that a partridge may not be killed at 60 and even 70 paces distance; but these shots are rare.

In shooting at a bird flying, or a hare running across, it is necessary to take aim at the fore part of the object. If a partridge flies across at the distance of 30 or 35 paces, it will be sufficient to aim at the head, or at most but a small space before it. Another thing to be attended to is, that the shooter ought not involuntarily to stop the motion of the arms at the moment of pulling the trigger; for the instant the hand stops in order to fire, however inconsiderable the time may be, the bird gets beyond the line of aim, and the shot will miss it. A sportsman ought therefore to accustom his hand while he is taking aim to follow the object. When a hare runs in a straight line from the shooter, he should take his aim between the ears, otherwise he will run the hazard either of missing, or at least not of killing dead, or, as it is sometimes called, clean.

A fowling-piece should not be fired more than 20 or 25 times without being washed; a barrel when foul neither shoots so ready, nor carries the shot so far, as when clean. The flint, pan, and hammer, should be well wiped after each shot; this contributes greatly to make the piece go off quick, but then it should be done with so much expedition, that the barrel may be reloaded whilst warm, for the reasons before advanced. The flint should be frequently changed, without waiting until it misses fire, before a new one is put in. Fifteen or eighteen shots, therefore, should only be fired with the same flint; the expence is too trifling to be regarded, and by changing it thus often much vexation will be prevented.

A gun also should never be fired with the prime of the preceding day; it may happen that an old priming will sometimes go off well, but it will more frequently contract moisture and fuze in the firing; then the object will most probably be missed, and that because the piece was not fresh primed.

For the information of the young sportsman we shall add a few more general directions. In warm weather he ought to seek for game in plains and open grounds; and in cold weather he may search little hills exposed to the sun, along hedges, among heath, in stubbles, and in pastures where there is much furze and fern. The morning is the best time of the day, before the dew is exhaled, and before the game has been disturbed. The colour of the shooter's dress ought to be the same with that of the fields and trees; in summer it ought to be green, in winter a dark grey. He ought to hunt as much as possible against the wind, not only to prevent the game perceiving the approach of him and his dog, but also to enable the dog to scent the game at a greater distance.

He should never be discouraged from hunting and ranging the same ground over and over again, especially in places covered with heath, brambles, high grass, or young coppice-wood. A hare or rabbit will frequently suffer him to pass several times within a few yards of its form without getting up. He should be still more patient when he has marked partridges into such places; for it often happens, that after the birds have been sprung many times, they lie so dead that they will suffer him almost to tread upon them before they will rise. Pheasants, quails, and woodcocks, do the same.

He ought to look carefully about him, never passing a bush, or tuft of grass, without examination; but he ought never to strike them with the muzzle of his gun, for it will loosen his wadding. He who patiently beats and ranges his ground over again, without being discouraged, will always kill the greatest quantity of game; and if he is shooting in company, he will find game where others have passed without discovering any.

When he has fired he should call in his dog, that he may not have the mortification to see game rise which he cannot shoot. When he has killed a bird, instead of being anxious about picking it up, he ought to follow the rest of the covey with his eye till he sees them settle.

Three species of dogs are capable of receiving the proper instructions and of being trained. These are the smooth pointer, the rough pointer, and the spaniel. The smooth pointer is active and lively enough in his range, but in general is proper only for an open country.

The greatest part of these dogs are afraid of water, brambles, and thickets; but the spaniel and the rough pointer are easily taught to take the water, even in cold weather, and to range the woods and rough places as well as the plain. Greater dependance may therefore be had on these two last species of dog than on the smooth pointer.

The education of a pointer may commence when he is only five or six months old. The only lessons which he can be taught at this time are, to fetch and carry any thing when desired; to come in when he runs far off, and to go behind when he returns; using, in the one case, the words here, come in, and in the other, back, or behind. It is also necessary at this period to accustom him to be tied up in the kennel or stable; but he ought not at first to be tied too long. He should be let loose in the morning, and fastened again in the evening. When a dog is not early accustomed to be chained, he disturbs every person in the neighbourhood by howling. It is also of importance that the person who is to train him should give him his food.

When the dog has attained the age of ten or twelve months, he may be carried into the field to be regularly trained. At first he may be allowed to follow his own inclination, and to run after every animal he sees. His indiscriminating eagerness will soon abate, and he will pursue only partridges and hares. He will soon become tired of following partridges in vain, and will content himself after having flushed them, to follow them with his eyes. It will be more difficult to prevent him from following hares.

All young dogs are apt to rake; that is, to hunt with their noses close to the ground, to follow birds rather by the track than by the wind. But partridges lie much better to dogs that wind them, than to those that follow them by the track. The dog that winds the scent approaches the birds by degrees, and without disturbing them; but they are immediately alarmed, when they see a dog tracing their footsteps. When you perceive that your dog is committing this fault, call to him in an angry tone, hold up; he will then grow uneasy and agitated, going first to the one side and then to the other, until the wind brings him the scent of the birds. After finding the game four or five times in this way, he will take the wind of himself, and hunt with his nose high. If it is difficult to correct this fault, it will be necessary to put the puzzle-peg upon him. This is of very simple construction, consisting only of a piece of oak or deal inch-board, one foot in length, and an inch and a half in breadth, tapering a little to one end; at the broader end are two holes running longitudinally, through which the collar of the dog is put, and the whole is buckled round his neck; the piece of wood being projected beyond his nose, is then fastened with a piece of leather thong to his under jaw. By this means the peg advancing seven or eight inches beyond his snout, the dog is prevented from putting his nose to the ground and raking.

As soon as the young dog knows his game, you must bring him under complete subjection. If he is tractable, this will be easy; but if he is stubborn, it will be necessary to use the trash cord, which is a rope or cord of 20 or 25 fathoms in length fastened to his collar. If he refuses to come back when called upon, you must check him smartly with the cord, which will often bring him upon his haunches. But be sure you never call to him except when you are within reach of the cord. After repeating this several times, he will not fail to come back when called; he ought then to be caressed, and a bit of bread should be given him. He ought now constantly to be tied up; and never unchained, except when you give him his food, and even then only when he has done something to deserve it.

The next step will be to throw down a piece of bread on the ground, at the same time taking hold of the dog by the collar, calling to him, "take heed,—softly." After having held him in this manner for some space of time, say to him "seize—lay hold." If he is impatient to lay hold of the piece of bread before the signal is given, correct him gently with a small whip. Repeat this lesson until he "takes heed" well, and no longer requires to be held fast to prevent him from laying hold of the bread. When he is well accustomed to this manege, turn the bread with a stick, holding it in the manner you do a fowling-piece, and having done so, cry seize. Never suffer the dog to eat either in the house or field, without having first made him take heed in this manner.

Then, in order to apply this lesson to the game, fry small pieces of bread in hog's lard, with the dung of partridge; take these in a linen bag into the fields, stubbles, ploughed grounds, and pastures, and there put the pieces in several different places, marking the spots with little cleft pickets of wood, which will be rendered more distinguishable by putting pieces of card in the nicks. This being done, cast off the dog and conduct him to these places, always hunting in the wind. After he has caught the scent of the bread, if he approaches too near, and seems eager to fall upon it, cry to him in a menacing tone, "take heed;" and if he does not stop immediately, correct him with the whip. He will soon comprehend what is required of him, and will stand.

At the next lesson, take your gun charged only with powder, walk gently round the piece of bread once or twice, and fire instead of crying seize. The next time of practising this lesson, walk round the bread four or five times, but in a greater circle than before, and continue to do this until the dog is conquered of his impatience, and will stand without moving until the signal is given him. When he keeps his point well, and stands steady in this lesson, you may carry him to the birds; if he runs in upon them, or barks when they spring up, you must correct him; and if he continues to do so, you must return to the fried bread; but this is seldom necessary.

When the dog has learned by this use of the bread to take heed, he may be carried to the fields with the trash-cord dragging on the ground. When he springs birds for the first time, if he runs after them or barks, check him by calling out to him, "take heed." If he points properly, caress him; but you ought never to hunt without the cord until he points staunch.

The principal objects of this sport are, 1. Partridges, which pair in the spring, and lay their eggs (generally from 15 to 20) during May and part of June. The young begin to fly about the end of June, and their plumage is complete in the beginning of October. The male has a conspicuous horse-shoe upon his breast, and an obtuse spur on the hinder part of the leg, which distinguishes him from the female. He is also rather larger.

When a sportsman is shooting in a country where the birds are thin, and he no longer chooses to range the field for the bare chance of meeting with them, the following method will show him where to find them on another day. In the evening, from sun-set to night-fall, he should post himself in a field, at the foot of a tree or a bush, and there wait until the partridges begin to call, or juck, which they always do at that time; not only for the purpose of drawing together when separated, but also when the birds composing the covey are not dispersed. After calling in this manner for some little space of time, the partridges will take to flight; then, if he marks the place where they alight, he may be assured they will lie there the whole night, unless disturbed.

2. The pheasant lays its eggs generally in the woods, the number of which is ten or twelve. Pheasants are accounted stupid birds; for when they are surprised they will frequently squat down like a rabbit, supposing themselves to be in safety as soon as their heads are concealed; and in this way they will sometimes suffer themselves to be killed with a stick. They love low and moist places, and haunt the edges of those pools which are found in woods, as well as the high grass of marshes that are near at hand; and above all, places where there are clumps of alders.

3. Grouse, or moor-game, are found in Wales, in the northern counties of England, and in great abundance in Scotland. They chiefly inhabit those mountains and moors which are covered with heath, and seldom descend to the low grounds. They fly in companies of four or five braces, and love to frequent mossy places, particularly in the middle of the day, or when the weather is warm. In pursuing this game, when the pointer sets, and the sportsman perceives the birds running with their heads erect, he must run after them as fast as he can, in the hope that he may get near enough to shoot when they rise upon the wing; for he may be pretty certain they will not lie well that day. As these birds are apt to grow soon putrid, they ought to be drawn carefully the instant they are shot, and stuffed with heath; and if the feathers happen to be wetted, they must be wiped dry.

4. The woodcock is a bird of passage; it commonly arrives about the end of October, and remains until the middle of March. Woodcocks are fattest in December and January, but from the end of February they are lean. At their arrival they drop any where, but afterwards take up their residence in copses of nine or ten years growth. They seldom, however, stay in one place longer than twelve or fifteen days. During the day they remain in those parts of the woods, where there are void spaces or glades, picking up earth-worms and grubs from the fallen leaves. In the evening they go to drink and wash their bills at pools and springs, after which they repair to the open fields and meadows for the night.

5. The snipe is a bird of passage as well as the woodcock. In the month of November they grow fat. Snipes frequent springs, bogs, and marshy places, and generally fly against the wind. The slant and cross shots are rather difficult, as the birds are small and fly very quickly. The sportsman ought to look for them in the direction of the wind; because then they will fly towards him, and present a fairer mark.

6. The wild duck also may in some measure be accounted a bird of passage, and arrives here in great flocks from the northern countries in the beginning of winter. Still, however, a great many remain in our marshes and fens during the whole year, and breed.

The wild duck differs little in plumage from the tame duck, but is easily distinguished by its size, which is less; by the neck, which is more slender; by the foot, which is smaller; by the nails, which are more black; and above all, by the web of the foot, which is much finer and softer to the touch.

In the summer season, when it is known that a team of young ducks are in a particular piece of water, and just beginning to fly, the sportsman is sure to find them early in the morning dabbling at the edges of the pool, and amongst the long grass, and then he may get very near to them: it is usual also to find them in those places at noon.

In the beginning of autumn almost every pool is frequented by teams of wild ducks, which remain there during the day, concealed in the rushes. If these pools are of small extent, two shooters, by going one on each side, making a noise and throwing stones into the rushes, will make them fly up; and they will in this way frequently get shots, especially if the pool is not broad, and contracts at one end. But the surest and most successful way, is to launch a small boat or trow on the pool, and to traverse the rushes by the openings which are found; at the same time making as little noise as possible. In this manner the ducks will suffer the sportsmen to come sufficiently near them to shoot flying; and it often happens that the ducks, after having flown up, only make a circuit, return in a little time, and again alight upon the pool. Then the sportsmen endeavour a second time to come near them. If several shooters are in company, they should divide; two should go in the boat, whilst the others spread themselves about the edge of the pool, in order to shoot the ducks in their flight. In pools which will not admit a trow, water-spaniels are absolutely necessary for this sport.

In winter they may be found on the margins of little pools; and when pools and rivers are frozen up, they must be watched for in places where there are springs and waters which do not freeze. The sport is then much more certain, because the ducks are confined to these places in order to procure aquatic herbs, which are almost their only food at this period.

SHORL. No word has been used by mineralogists with less limitation than shorl. It was first introduced into mineralogy by Cronstedt, to denote any stone of a columnar form, considerable hardness, and a specific gravity from 3 to 3.4. This description applied to a very great number of stones; and succeeding mineralogists, though they made the word more definite in its signification, left it still so general, that under the designation of shorl almost twenty distinct species of minerals were included. Mr. Werner first defined the word shorl precisely, and restricted it to one species of stones. It occurs commonly in granite, gneiss, and other similar rocks; often in mass, but very frequently crystallised. The primitive form of its crystals is an obtuse rhomboid, the solid angle at the summit of which is 139°, having rhombid faces, with angles of 114° 12′ and 65° 48′: but it usually occurs in 3, 6, 8, 9, or 12 sided prisms, terminated by four or five-sided summits, variously truncated.

SHORL, *black*. Colour black. Found in mass, disseminated and crystallized. Crystals three-sided prisms, having their lateral edges truncated. Sometimes terminating in a pyramid. Lateral faces of the prism striated. Vitreous. Fracture conchoidal. Opaque. Scratch grey. Feel cold. Specific gravity from 3 to 3. It becomes electric by heat. When heated to redness, its colour becomes brownish red; and at 127° Wedgewood, it is converted into a brownish compact enamel. According to Wiegleb, it is composed of

41.25	alumina
34.16	silica
20.00	iron
5.41	manganese
100.82.	

SHORL electric. This stone was first made known in Europe by specimens brought from Ceylon; but it is now found frequently forming a part of the composition of mountains. It is sometimes in amorphous pieces, but much more frequently crystallized in three or nine-sided prisms, with four-sided summits.

Colour usually green; sometimes brown, red, blue. Found in mass, in grains, and crystallized. Crystals three, six, or nine-sided prisms, variously truncated. Faces usually striated longitudinally. Its texture is foliated. Specific gravity 3. Colour brown, sometimes with a tint of green, blue, red, or yellow. When heated to 200° Fahrenheit, it becomes electric, one of the summits negatively and the other positively. It reddens when heated, and is fusible per se, with white intumescence, into a white or grey enamel. According to Vauquelin, it is composed of

40	silica
39	alumina
12	oxide of iron
4	lime
2.5	oxide of manganese
97.5	

SHORLITE, a stone which received its name from Mr. Klaproth, is generally found in oblong masses, which, when regular, are six-sided prisms, inserted in granite. Its

texture is foliated. Fracture uneven. Easily broken. Specific gravity 3.53. Colour greenish or yellowish white; sometimes sulphur yellow. Not altered by heat. According to the analysis of Klaproth, it is composed of 50 alumina
50 silica
———
100.

According to Vauquelin, of 52.6 alumina
36.8 silica
3.3 lime
1.5 water.
———
94.2

SHORT-HAND. See STENOGRAPHY.

SHOT, a denomination given to all sorts of balls for fire-arms; those for cannon being of iron, and those for guns, pistols, &c. of lead.

SHOT, *case*, formerly consisted of all kinds of old iron, nails, musket-balls, stones, &c. used as above.

SHOT *of a cable*, on ship-board, is the splicing of two cables together, that a ship may ride safe in deep waters and in great roads; for a ship will ride easier by one shot of a cable, than by three short cables out ahead.

SHOT, *grape*. See GRAPE-SHOT.

SHOT, *patent milled*, is thus made; sheets of lead, whose thickness corresponds with the size of the shot required, are cut into small pieces, or cubes, of the form of a die. A great quantity of these little cubes are put into a large hollow iron cylinder, which is mounted horizontally and turned by a winch; when by their friction against one another, and against the sides of the cylinder, they are rendered perfectly round and very smooth. The other patent-shot is cast in moulds, in the same way as bullets are.

SHOT, *common small*, or that used for fowling, should be well sized; for, should it be too great, then it flies thin and scatters too much; or if too small, then it has not weight and strength to penetrate far, and the bird is apt to fly away with it. In order, therefore, to have it suitable to the occasion, it not being always to be had in every place fit for the purpose, we shall set down the true method of making all sorts and sizes under the name of mould-shot, formerly made after the following process:

Take any quantity of lead you think fit, and melt it down in an iron vessel; and as it melts keep it stirring with an iron ladle, skimming off all impurities whatsoever that may arise at top; when it begins to look of a greenish colour, strew on it as much auripigmentum or yellow orpiment, finely powdered, as will lie on a shilling, to every twelve or fourteen pounds of lead; then stirring them together, the orpiment will flame. The ladle should have a notch on one side of the brim, for more easily pouring out the lead; the ladle must remain in the melted lead, that its heat may be the same with that of the lead, to prevent inconveniences which otherwise might happen by its being either too hot or too cold; then, to try your lead, drop a little of it into water, and if the drops prove round, then the lead is of a proper heat; if otherwise, and the shot have tails, then add more orpiment to increase the heat, till it is found sufficient.

Then take a plate of copper, about the size of a trencher, which must be made with a hollowness in the middle, about three inches compass, within which must be bored about 40 holes according to the size of the shot which you intend to cast; the hollow bottom should be thin; but the thicker the brim, the better it will retain the heat. Place this plate on a frame of iron, over a tube or vessel of water, about four inches from the water, and spread burning coals on the plate, to keep the lead melted upon it; then take some lead and pour it gently on the coals on the plate, and it will make its way through the holes into the water, and form itself into shot; do thus till all your lead is run through the holes of the plate, taking care, by keeping your coals alive, that the lead does not cool, and so stop up the holes.

While you are casting in this manner, another person with another ladle may catch some of the shot, placing the ladle four or five inches underneath the plate in the water, by which means you will see if they are defective, and rectify them. Your chief care is to keep the lead in a just degree of heat, that it shall be not so cold as to stop up the holes in your plate, nor so hot as to cause the shot to crack; to remedy the heat, you must refrain working till it is of a proper coolness; and to remedy the coolness of your lead and plate, you must blow your fire; observing, that the cooler your lead is, the larger will be your shot; as, the hotter it is, the smaller they will be.

After you have done casting, take them out of the water, and dry them over the fire with a gentle heat, stirring them continually that they do not melt; when dry, you are to separate the great shot from the small, by the help of a sieve made for that purpose, according to their several sizes. But those who would have very large shot, make the lead trickle with a stick out of the ladle into the water, without the plate. If it stops on the plate, and yet the plate is not too cool, give but the plate a little knock, and it will run again; care must be had that none of your implements are greasy, oily, or the like; and when the shot, being separated, are found too large or too small for your purpose, or otherwise imperfect, they will serve again at the next operation.

SHOT, *tin-case*, in artillery, is formed by putting a great quantity of small iron shot into a tin cylindrical box called a cannister, that just fits the bore of the gun. Leaden bullets are sometimes used in the same manner; and it must be observed, that whatever number or sizes of the shots are used, they must weigh with their cases nearly as much as the shot of the piece.

SHREW-MOUSE. See SOREX.

SHRIMP. See CANCER.

SHRINE, in ecclesiastical history, a case or box, to hold the relics of some saint.

SHROUDS. See SHROWDS.

SHROWDS, or SHROUDS, in a ship, are the great ropes which come down both sides of the masts, and are fastened below to the chains on the ship's side, and aloft to the top of the mast; being parcelled and served, in order to prevent the mast's galling them. The topmast shrowds are fastened to the puttock-plates, by dead-eyes and laniards, as the others are. Some of the terms relating to the shrowds are: ease the shrowds; that is, slacken them: and, set up the shrowds; that is, set them stiffer.

SHUTTLE, in the manufactures, an instrument much used by weavers, in the middle of which is an eye, or cavity, wherein is inclosed the spoul with the woof. See WEAVING.

SI, in music; a seventh note or sound, added by Le Maire to the six antient notes invented by Guido Aretine, viz. ut. re, mi, fa, sol, la, si.

SIBBALDIA, a genus of plants belonging to the class of pentandria, and to the order of pentagynia; and in the natural method ranking under the 35th order, senticosæ. The calyx is divided into ten segments. The petals are five, and are inserted into the calyx. The styles are attached to the side of the germens. The seeds are five. There are three species belonging to this genus, the procumbens, erecta, and altaica. The procumbens, or reclining sibbaldia, is a native of North Britain.

SIBTHORPIA, a genus of plants belonging to the class of didynamia, and to the order of angiospermia; and in the natural system classed with those the order of which is doubtful. The calyx is spreading, and divided into five parts, almost to the base. The corolla is divided into five parts in the same manner, which are rounded, equal, spreading, and of the length of the calyx. The stamina grow in pairs at a distance from each other. The capsule is compressed, orbicular, bilocular, the partition being transverse. There is one species; the Europæa, or bastard money-wort, a native of South Britain. It blossoms from July to September, and is found in Cornwall on the banks of rivulets.

SICE-ACE, a game with dice and tables, whereat five may play; each having six men, and the last out losing. At this game, they load one another with aces; sixes bear away; and doublets drinks, and throws again.

SICYOS, a genus of plants belonging to the class of monœcia, and to the order of syngenesia; and in the natural system arranged under the 34th order, cucurbitaceæ. The male flowers have their calyx quinquedentated, their corolla quinquepartite, and there are three filaments. The female flowers have their calyx and corolla similar; but their style is trifid, and their drupe monospermous. There are three species, the angulata, laciniata, and garcini, which are all foreign plants.

SIDA, yellow or Indian mallow: a genus of plants belonging to the class of monadelphia, and to the order of polyandria; and in the natural system ranking under the 37th order, columniferæ. The calyx is simple and angulated; the style is divided into many parts; there are several capsules, each containing one seed. There are 99 species, all natives of warm climates; and most of them are found in the East or West Indies. The Chinese make cords of the sida abutilon. This plant loves water, and may be advantageously planted in marshes and ditches, where nothing else will grow. The maceration of the smaller stalks is finished in about fifteen days; of the larger in a month. The strength and goodness of the thread appears to be in proportion to the perfection of the vegetation, and to the distance the plant is kept at from other plants. The fibres lie in strata, of which there are sometimes six; they are not quite straight, but preserve an undulating direction, so as to form a network in their natural positions. Their smell resembles that of hemp; the fibres are whiter, but more dry and harsh, than those of hemp. The harshness is owing to a greenish gluten which connects the fibres; and the white colour must always be obtained at the expence of having this kind of thread less supple; when of its natural hue, it is very soft and flexible.

SIDERIA, in natural history, the name of a genus of crystals, used to express those altered in their figure by particles of iron. These are of a rhomboidal figure, and composed only of six planes. Of this genus there are four known species: 1. A colourless, pellucid, and thin one; found in considerable quantities among the iron ores of the forest of Dean in Gloucestershire, and in several other places. 2. A dull, thick, and brown one, not uncommon in the same places with the former. And, 3. A black and very glossy kind, a fossil of great beauty; found in the same place with the others, as also in Leicestershire and Sussex.

SIDERITE, a substance discovered by Mr. Meyer, and by him supposed to be a new metal; but Messrs. Bergman and Kirwan discovered that it is nothing else than a natural combination of the phosphoric acid with iron. Mr. Klaproth of Berlin also came to the same conclusion, without any communication with Mr. Meyer. It is extremely difficult to separate this acid from the metal; however, he found the artificial compound of phosphoric acid and iron to agree in its properties with the calx sideri alba, obtained by Bergman and Meyer from the cold short iron extracted from the swampy or marshy ores.

SIDERITIS, Ironwort; a genus of plants belonging to the class of didynamia, and to the order of gymnospermia; and in the natural system ranging under the 42d order, verticillatæ. The stamina are within the tube of the corolla. There are two stigmas, one of which is cylindrical and concave; the other, which is lower, is membranous, shorter, and sheathing the other. The species are 19.

SIDEROXYLUM, Iron-wood: a genus of plants belonging to the class of pentandria, and to the order of monogynia; and in the natural system ranging under the 43d order, dumosæ. The corolla is cut into five parts, the laciniæ or segments being incurvated alternately; the stigma is simple; the berry contains five seeds. There are nine species; 1. Mite; 2. inerme, smooth iron-wood; 3. melanophleum, laurel-leaved iron-wood; 4. cymosum; 5. sericeum, silky iron-wood, native of New South Wales; 6. tomentosum; 7. tenax, silvery-leaved iron-wood, a native of Carolina; 8. lycioides, willow-leaved iron-wood, a native of North America; 9. decandrum. The wood of these trees being very close and solid, has given occasion for this name to be applied to them, it being so heavy as to sink in water. As they are natives of warm countries, they cannot be preserved in this country unless they are placed, the two former in a warm stove, the others in a green-house. They are propagated by seeds, when these can be procured from abroad.

SIEGE, in the art of war, the encampment of an army before a fortified place, with a design to take it.

SIENITE. See Rocks, *primitive*.

SIGESBECKIA, a genus of plants belonging to the class syngenesia, and to the order of polygamia superflua, and in the natural system ranging under the 49th order, compositæ. The receptacle is paleaceous; the pappus wanting; the exterior calyx is pentaphyllous, proper, and spreading; the radius is halved. There are three species: 1. The orientalis, which is a native of India and China. 2. The occidentalis, which is a native of Virginia. 3. The flosculosa, a native of Peru.

SIGHTS *of a quadrant*, &c. thin pieces of brass, raised perpendicularly on its side, or on the index of a theodolite, circumferentor, &c. They have each an aperture, or slit, up the middle, through which the visual rays pass to the eye, and distant objects are seen.

Sights *of a gun*. See Rifle.

SIGN, in astronomy, a constellation containing a twelfth part of the zodiac, or 30°. See Zodiac.

The names of the signs, in the order wherein they follow each other, are aries, taurus, gemini, cancer, leo, virgo, libra, scorpio, sagittarius, capricornus, aquarius, pisces. The three first of these signs are called the vernal, or spring-signs; the next three, cancer, leo, virgo, the æstival, or summer-signs; libra, scorpio, and sagittarius, the autumnal signs; and capricornus, aquarius, pisces, the brumal, or winter-signs. The vernal and æstival signs are also called the northern, and the autumnal and brumal the southern signs.

Sign-manual, in law, is used to signify a bill, or writing, signed by the king's own hand-writing.

SIGNALS, certain alarms or notices used to communicate intelligence to a distant observer. Signals are made by firing artillery, and displaying colours, lanterns, or fireworks; and these are combined by multiplication and repetition. Thus, like the words of a language, they become arbitrary expressions, to which we have previously annexed particular ideas; and hence they are the general sources of intelligence throughout a naval armament, &c.

Signals ought to be distinct, with simplicity. They are simple when every instruction is expressed by a particular token, in order to avoid any mistakes arising from the double purport of one signal. They are distinct when issued without precipitation, when sufficient time is allowed to observe and obey them, and when they are exposed in a conspicuous place, so as to be readily perceived at a distance.

All signals may be reduced into three different kinds, viz. those which are made by the sound of particular instruments, as the trumpet, horn, or fife; to which may be added, striking the bell, or beating the drum. Those which are made by displaying pendants, ensigns, and flags of different colours; or by lowering or altering the position of the sails; and, finally, those which are executed by rockets of different kinds; by firing cannon or small arms; by artificial fire-works; and by lanterns.

Firing of great guns will serve equally in the day or night, or in a fog, to make or confirm signals, or to raise the attention of the hearers to a future order. This method, however, is attended with some inconveniences, and should not be used indiscriminately. Too great a report of the cannon is apt to introduce mistakes and confusion, as well as to discover the track of the squadron. The report and flight of rockets is liable to the same objection, when at a short distance from the enemy.

It is then by the combination of signals, previously known, that the admiral conveys orders to his fleet; every squadron, every division, and every ship of which, has its particular signal. The instruction may therefore occasionally be given to the whole fleet, or to any of its squadrons; to any division of those squadrons, or to any ship of those divisions.

Hence the signal of command may at the same time be displayed for three divisions, and for three ships of each division; or for three ships in each squadron, and for only nine ships in the whole fleet. For, the general signal of the fleet being shown, if a particular pendant is also thrown out from some particular place on the same mast with the general signal, it will communicate intelligence to nine ships that wear the same pendant.

The preparatory signal given by the admiral to the whole or any part of his fleet, is immediately answered by those to whom it is directed; by showing the same signal, to testify that they are ready to put his orders in execution. Having observed their answer, he will show the signal which is to direct their operations: as, to chase, to form the line, to begin the engagement, to board, to double upon the enemy, to rally or return to action, to discontinue the fight, to retreat and save themselves. The dexterity of working the ships in a fleet depends on the precise moment of executing these orders, and on the general harmony of their movements; a circumstance which evinces the utility of a signal of preparation.

As the extent of the line of battle, and the fire and smoke of the action, or other circumstances in navigation, will frequently prevent the admiral's signals from being seen throughout the fleet, they are always repeated by the officers next in command, by ships appointed to repeat signals; and, finally, by the ship or ships for which they are intended.

The ships that repeat the signals, besides the chiefs of squadrons or divisions, are usually frigates lying to windward or to leeward of the line. They should be extremely vigilant to observe and repeat the signals, whether they are to transmit the orders of the commander in chief, or his seconds, to any part of the fleet; or to report the fortunate or distressful situation of any part thereof. By this means all the ships from the van to the rear will, unless disabled, be ready at a moment's warning to put the admiral's designs in execution.

To preserve order in the repetition of signals, and to favour their communication, without embarrassment, from the commander in chief to the ship for which they are calculated, the commanders of the squadrons repeat after the admiral; the chiefs of the divisions, according to their order of the line, after the commanders of the squadrons; and the particular ships after the chiefs of the divisions;

and those in return, after the particular ships, vice versa, when the object is to convey any intelligence from the latter to the admiral.

Besides the signals above-mentioned, there are others for different ranks of officers; as for captains, lieutenants, masters, &c. or for any of those officers of a peculiar ship.

SIGNALS *by the drum*, made use of, in the exercise of the army, instead of the word of command, viz.

SIGNALS.	*Operations.*
A short roll,	To caution.
A flam,	To perform any distinct thing.
To arms,	To form the line or battalion.
The march,	To advance, except when intended for a salute.
The quick march,	To advance quick.
The point of war,	To march and charge.
The retreat,	To retreat.
Drum ceasing,	To halt.
Two short rolls,	To perform the flank-firing.
The dragoon march,	To open the battalion.
The grenadier march,	To form the column.
The troop,	To double divisions.
The long roll,	To form the square.
The grenadier march,	To reduce the square to the column.
The preparative,	To make ready and fire.
The general,	To cease firing.
Two long rolls,	To bring or lodge the colours.

SIGNATURE, in printing, is a letter put at the bottom of the first page at least, in each sheet, as a direction to the binder, in folding, gathering, and collating them. The signatures consist of the capital letters of the alphabet, which change in every sheet: if there are more sheets than letters in the alphabet, to the capital letter is added a small one of the same sort, as Aa, Bb; which are repeated as often as necessary. In large volumes it is usual to distinguish the number of alphabets, after the first three or four, by placing a figure before the signature, as 5B, 6B, &c.

SIGNET, one of the king's seals, made use of in sealing his private letters, and all grants that pass by bill signed under his majesty's hand: it is always in the custody of the secretaries of state.

SIGNIFICAVIT, in law, a writ which issues out of the court of chancery, on a certificate given by the ordinary of a person's standing excommunicated forty days, in order to have him imprisoned till he submits to the authority of the church.

SILENE, *catchfly*, or *viscous campion*, a genus of plants belonging to the class of decandria, and order of trigynia; and in the natural system arranged under the 22d order, caryophylleæ. The calyx is ventricose; the petals are five in number, bifid and unguiculated, and crowned by a nectarium; the capsule is cylindrical, covered, and trilocular. There are 66 species, of which seven are natives of Britain and Ireland.

SILICA. There is a very hard white stone, known by the name of quartz, very common in almost every part of the world. Sometimes it is transparent and crystallized, and then is called rock crystal. Very frequently it is in the form of sand. As this stone, and several others which resemble it, as flint, agate, calcedony, &c. have the property of melting into a glass when heated along with fixed alkali, they were classed together by mineralogists under the name of vitrifiable stones. Mr. Pott, who first described their properties in 1746, gave them the name of siliceous stones, on the supposition that they were all chiefly composed of a peculiar earth called siliceous earth or silica. This earth was known to Glauber, who describes the method of obtaining it: but it was long before its properties were accurately ascertained. Geoffroy endeavoured to prove that it might be converted into lime, and Pott and Beaumé that it might be converted into alumina: but these assertions were refuted by Cartheuser, Scheele, and Bergman. To this last chemist we are indebted for the first accurate detail of the properties of silica.

1. Silica may be obtained pure by the following process: Mix together, in a crucible, one part of pounded flint or quartz, and three parts of potass, and apply a heat sufficient to melt the mixture completely. Dissolve the mass formed in water, saturate the potass with muriatic acid, and evaporate to dryness. Towards the end of the evaporation the liquid assumes the form of a jelly; and when all the moisture is evaporated, a white mass remains behind. This mass is to be washed in a large quantity of water, and dried; it is then silica in a state of purity.

2. Silica, thus obtained, is a fine white powder, without either taste or smell. Its particles have a harsh feel, as if they consisted of very minute grains of sand. Its specific gravity is 2.66.

It may be subjected to a very violent heat without undergoing any change. Lavoisier and Morveau exposed it to the action of a fire maintained by oxygen gas without any alteration. Saussure, indeed, has succeeded in fusing, by means of the blowpipe, a portion of it so extremely minute as scarcely to be perceptible without a glass. According to the calculation of this philosopher, the temperature necessary for producing this effect is equal to 4043° Wedgewood.

3. It is insoluble in water except when newly precipitated, and then one part of it is soluble in 1000 parts of water. It has no effect on vegetable colours.

It is capable of absorbing about one-fourth of its weight of water, without letting any drop from it; but on exposure to the air, the water evaporates very readily. When precipitated from potass by means of muriatic acid and slow evaporation, it retains a considerable portion of water, and forms with it a transparent jelly; but the moisture gradually evaporates on exposure to the air.

Silica may be formed into a paste with a small quantity of water: this paste has not the smallest ductility, and when dried forms a loose, friable, and incoherent mass.

Silica is capable of assuming a crystalline form. Crystals of it are found in many parts of the world. They are known by the name of rock crystal. When pure they are transparent and colourless like glass: they assume various forms; the most usual is a hexagonal prism, surmounted with hexagonal pyramids on one or both ends, the angles of the prism corresponding with those of the pyramids. Their hardness is very great, amounting to 11. Their specific gravity is 2.653.

4. Silica neither combines with oxygen, with the simple combustibles, nor with metals; but it combines with many of the metallic oxides by fusion, and forms various coloured glasses and enamels.

5. Azote has no action on silica, neither has muriatic acid when the silica is in a solid state; but when the silica is combined with an excess of alkali, muriatic acid dissolves the compound, and forms a permanent solution. By concentrating this solution, the silica separates from it in the form of a jelly.

6. There is a strong affinity between silica and fixed alkalies. It may be combined with them either by fusing them along with it in a crucible, or by boiling the liquid alkalies over it. When the potass exceeds the silica considerably, the compound is soluble in water, and constitutes what was formerly called liquor silicum, and now sometimes silicated potass or soda. When the silica exceeds, the compound is transparent and colourless like rock crystal, and is neither acted on by water, air, nor (excepting one) by acids. This is the substance so well known under the name of glass. See GLASS.

Silica is not acted on by ammonia, whether in the gaseous or liquid state.

7. There is a strong affinity between barytes and silica. When barytes water is poured into a solution of silica in potass, a precipitate appears, which is considered by Morveau as the two earths in a state of combination. Barytes and silica may be combined by means of heat. The compound is of a greenish colour, and coheres but imperfectly. The effect of heat on various mixtures of barytes and silica will appear from the following experiments of Mr. Kirwan:

Proportions.	Heat.	Effect.
80 Silica 20 Barytes	155° Wedg.	A white brittle mass.
75 Silica 20 Barytes	150	A brittle hard mass, semitransparent at the edges.
66 Silica 33 Barytes	150	Melted into a hard somewhat porous porcelain mass.

Proportions.	Heat.	Effect.
50 Silica 50 Barytes	148	A hard mass not melted.
20 Silica 80 Barytes	148	The edges were melted into a pale greenish matter between a porcelain and enamel.
25 Silica 75 Barytes	150	Melted into a somewhat porous porcelain.
33 Silica 66 Barytes	150	Melted into a yellowish and partly greenish white porous porcelain.

Strontian and silica combine with each other nearly in the same manner.

There is also an affinity between silica and lime. When lime-water is poured into a solution of silica in potass, a precipitate appears, as Stucke discovered. This precipitate is a compound of silica and lime. These two earths may be combined also by means of heat. They form a glass, provided the quantity of lime is not inferior to that of silica. The effect of heat upon these earths, mixed in various proportions, will appear from the following experiments of Mr. Kirwan:

Proportions.	Heat.	Effect.
50 Lime 50 Silica	150° Wedg.	Melted into a mass of a whitish colour, semi-transparent at the edges, and striking fire, though feebly, with steel: it was somewhat between porcelain and enamel.
80 Lime 20 Silica	156	A yellowish white loose powder.
20 Lime 80 Silica	156	Not melted, formed a brittle mass.

Equal parts of magnesia and silica melt with great difficulty into a white enamel when exposed to the most violent heat which can be produced. They are infusible in inferior heats, in whatever proportion they are mixed.

There is a strong affinity between alumina and silica. When equal portions of silicated and aluminated potass are mixed together, a brown zone immediately appears, which may be made, by agitation, to pass through the whole liquid. After standing about an hour, the mixture assumes the consistence of jelly. When formed into a paste with water, and dried, they cohere, and contract a considerable degree of hardness. When baked in the temperature of 160° Wedgewood, they become very hard, but do not fuse. Achard found them infusible in all proportions in a heat probably little inferior to 150° of Wedgewood. But when exposed to a very strong heat, they are converted into a kind of opaque glass, or rather enamel. Porcelain, stone ware, brick, tiles, and other similar substances, are composed chiefly of this compound. Mixtures of silica and alumina in various proportions constitute clays; but these are seldom uncontaminated with other ingredients.

It follows from the experiments of Achard, that equal parts of lime, magnesia, and silica, may be melted into a greenish-coloured glass, hard enough to strike fire with steel; that when the magnesia exceeds either of the other two, the mixture will not melt; that when the silica exceeds, the mixture seldom melts, only indeed with lime in the following proportions; three silica, two lime, one magnesia, which formed a porcelain; and that when the lime exceeds, the mixture is generally fusible.

A mixture of silica and alumina may also be combined with barytes or strontian by means of heat. The mixture melts readily into a greenish-coloured porcelain.

From the experiments of Achard and Kirwan, we learn that, in mixtures of lime, silica, and alumina, when the lime exceeds, the mixture is generally fusible either into a glass or a porcelain, according to the proportions. That if the silica exceeds, the mixture is frequently fusible into an enamel or porcelain, and perhaps a glass; and that when the alumina exceeds, a porcelain may often be attained, but not a glass.

As to mixtures of magnesia, silica, and alumina, when the magnesia exceeds, no fusion takes place at 150°. When the silica exceeds, a porcelain may often be attained; and three parts silica, two magnesia, and one alumina, form a glass. When the alumina exceeds, nothing more than a porcelain can be produced.

Achard found that equal parts of lime, magnesia, silica, and alumina, melted into a glass. They fused also in various other proportions, especially when the silica predominated.

Silica differs from all the other earths in not combining with any of the acids except the fluoric, phosphoric, and boracic; to which, perhaps, we may add the muriatic.

Silica is one of the most important of the earths. It is the chief ingredient of those stones which seem to constitute the basis of this terrestrial globe. It is an essential ingredient in mortar, in all kinds of stone ware, and in glass.

SILK, in natural history, is the production of different species of caterpillars. The phalæna, or bombyx mori, is most commonly propagated for that purpose in Europe; but the phalena atlas yields a greater quantity. See Bombyx, and Phalæna. A similar substance, indeed, is yielded by the greater number of the tribe of caterpillars. It is found inclosed in two small bags, from which it is protruded in fine threads to serve the insect for a covering during its chrysalis state. The webs of spiders are obviously of the same nature with silk; though their fibres, at least in this country, are finer and weaker. Reaumur and other naturalists ascertained, that the larger species of spiders spun webs sufficiently strong to be manufactured, and that the produce was neither inferior in beauty nor in strength to the silk of the silkworm. See Aranea.

The silkworm is a native of China, and feeds on the leaves of the white mulberry. That industrious nation was acquainted with the manufacture of silk from the most remote ages; but it was scarcely known in Europe before the time of Augustus. Its beauty attracted the attention of the luxurious Romans; and after the effeminate reign of Elagabulus, it became a common article of dress. It was brought from China at an enormous expence, manufactured again by the Phœnicians, and sold at Rome for its weight of gold. In the reign of Justinian this commerce was interrupted by the conquests of the Scythian tribes, and all attempts to procure it failed till two Persian monks had the address to convey some of the eggs of the insect from China to Constantinople, concealed in the hollow of a cane. They were hatched, and the breed carefully propagated. This happened in 555; and some years after we find that the Greeks understood the art of procuring and manufacturing silk as well as the Orientals. Roger, king of Sicily, brought the manufacture to that island in 1130, forcibly carrying off the weavers from Greece, and settling them in Sicily. From that island the art passed into Italy, and thence into France: and the revocation of the edict of Nantz established the manufactory of silk in Britain.

Silk, as spun by the animal, is in the state of fine threads, varying in colour from white to reddish yellow. It is very elastic, and has considerable strength, if we consider its small diameter. It is covered with a varnish, to which its elasticity is owing. This varnish is soluble in boiling water; but alcohol does not act upon it. Hence it has been compared to a gum, though it approaches much nearer to a gelatine; since Berthollet has shewn that it is precipitated by tan and by muriat of tin. It differs, however, from gelatine in several particulars. Alum throws it down of a dirty white, sulphat of copper of a dark brown, and sulphat of iron of a brown colour. When the water is evaporated, the varnish is obtained of a black colour, brittle, and of a shining fracture. Its weight is nearly one-third of the raw silk from which it was extracted. It may be separated from silk by soap as well as water, and the soap leys containing it soon putrefy.

Besides the varnish, silk contains another substance to which it owes its yellow colour. This substance possesses the properties of resin. It is yellow, soluble in alcohol, and in a mixture of alcohol and muriatic acid. Beaumé has ascertained, that by this last mixture it may be separated completely, and the silk deprived of it assumes a fine white colour.

The chemical properties of silk itself have been but imperfectly examined. It is not acted on by water or alcohol, has no taste, and is but imperfectly combustible; though fire rapidly blackens and decomposes it. When distilled, it yields, according to Neumann, an uncommonly great proportion of ammonia.

The fixed alkalies dissolve it by the assistance of heat; and it is not unlikely that they form with it an animal soap.

It is dissolved likewise by sulphuric and muriatic acids, and by nitric acid. By the action of this last acid, Berthollet obtained from silk some oxalic acid, and a fatty matter which swam on the surface of the solution. By a similar treatment, Welter obtained fine yellow crystals, very combustible, to which he gave the name of yellow bitter principle.

Silk is very little susceptible of putrefaction. Dr. Wilson, of Falkirk, says, that a ribbon was lately found in the churchyard of that town wrapt round the bone of the arm. It was uninjured, though it had lain eight years in the earth. We know, at the same time, that when silk is kept in a damp place it rots (to use the common language) in a much shorter time.

Silk, *manufacture, or preparation of.* When the silkworms have completed their balls or cocoons (see Phalæna, Vol. II. p. 389), they are collected, and put into little baskets; and thus exposed to the heat of an oven, to kill the insect, which, without this precaution, would not fail to open itself to go away and use those new wings abroad, it has acquired within.

Ordinarily, they only wind the more perfect balls; those that are double, or too weak, or too coarse, are laid aside, not as altogether useless, but that, being improper for winding, they are reserved to be drawn out into skains. The balls are of different colours; the most common are yellow, orange-colour, isabella, and flesh-colour; there are some also of a sea-green, others of a sulphur-colour, and others white; but there is no necessity for separating the colours and shades to wind them apart, as all the colours are to be lost in the future scouring and preparing of the silk.

The goodness of silk is best distinguished by its lightness. The organzine silk is the best of any made in the country of Piedmont, and two threads are equal in fineness, that is, in smoothness, thickness, and length, for the thread of the first twist. For the second, it matters not whether the single thread is strong before the two are joined, unless to see whether the first twist proves well. It is necessary that the silk be clean; and it is to be observed, that the straw-coloured is generally the lightest, and the white the heaviest of all. The skains should be even, and all of an equality, which shews that they were wrought together; otherwise we may with justice suspect that it is refuse silk, and cannot be equally drawn out and spun, for one thread will be shorter than the other, which is labour and loss. It will also be requisite to search the bale more than once, and take from out of the parcels a skain to make an essay; for unless it is known by trial, there is the greatest danger of being cheated in this commodity. To wind silk from off the balls, two machines are necessary; the one a furnace, with its copper; the other a reel, or frame, to draw the silk. The winder then, seated near the furnace, throws into the copper of water over the furnace (first heated and boiled to a certain degree, which custom alone can teach) a handful or two of balls, which have been first well purged of all their loose furry substance. She then stirs the whole very briskly about with birchen rods, bound and cut like brushes; and when the heat and agitation have detached the ends of the silks of the cocoons, which are apt to catch on the rods, she draws them forth, and joining ten or twelve, or even fourteen of them together, she forms them into threads, according to the size required to the works they are destined for: eight ends sufficing for ribands; and velvets, &c. requiring no less than fourteen. The ends, thus joined into two or three threads, are first passed into the holes of three iron rods, in the fore-part of the reel, then upon the bobbins or pulleys, and at last are drawn out to the reel itself, and there fastened; each to an end of an arm or branch of the reel. Thus disposed, the winder, giving motion to the reel, by turning the handle, guides the threads; substitutes new ones, when any of them break, or any of the balls are wound out; strengthens them, where necessary, by adding others; and takes away the balls wound out, or that, having been pierced, are full of water.

In this manner, two persons will spin and reel three pounds of silk in a day, which is done with greater dispatch than is made by the spinning-wheel or distaff. Indeed, all silks cannot be spun and reeled after this manner; either because the balls have been perforated by the silkworms themselves, or because they are double, or too weak to bear the water; or because they are coarse, &c. Of all these together, they make a particular kind of silk, called floretta; which being carded, or even spun on the distaff, or the wheel, in the condition it comes from the ball, makes a tolerable silk.

As to the balls, after opening them with scissars, and taking out the insects (which are of some use for the feeding of poultry), they are steeped three or four days in troughs, the water of which is changed every day to prevent their stinking. When they are well softened by this scouring, and cleared of that gummy matter the worm had lined the inside with, and which renders it impenetrable to the water, and even to air itself, they boil them half an hour in a lye of ashes, very clear and well strained: and after washing them out in the river, and drying them in the sun, they card and spin them on the wheel, &c. and thus make another kind of floretta, somewhat inferior to the former.

As to the spinning and reeling of raw silks off the balls, such as they are brought from Italy and the Levant, the first is chiefly performed on the spinning-wheel; and the latter, either on hand-reels, or on reels mounted on machines, which serve to reel several skains at the same time.

As to the milling, they use a mill composed of several pieces, which may mill two or three hundred bobbins at once, and make them into as many skains.

For the dyeing of silks, see Dyeing.

SILPHA, a genus of insects of the order coleoptera. The generic character is, antennæ thickening towards the tip; wing-sheaths margined; head prominent; thorax flattish, margined. The insects of the genus silpha, of which there are 35 species, are generally found among decaying animal or vegetable substances, frequenting dung-hills, carrion, &c. and deposit their eggs chiefly in the latter. The larvæ are of a lengthened shape, and of an unpleasant appearance, being generally roughened with minute spines and protuberances. The most remarkable of the European species, and which is by no means uncommon in our own country, is the silpha vespillo, distinguished by having the wing-sheaths considerably shorter than the abdomen, or as if cut off at the tips: they are also each marked by two waved, orange-coloured, transverse bars, the rest of the insect being black: the general length of the animal is about three quarters of an inch. This insect seeks out some decaying animal substance in which it may deposit its eggs, and in order to their greater security, contrives to bury it under ground. Three or four insects, working in concert, have been known to drag under the surface the body of so large an animal as a mole in the space of an hour, so that no trace of it has appeared above ground. The eggs deposited by the parent insects are white, and of an oval or rather subcylindric shape: from these are hatched the larvæ, which, when full-grown, are more than an inch in length, and of a yellowish-white colour, with a scaly orange-coloured shield or bar across the middle of each division of the body. Each of these larvæ forms for itself an oval cell in the ground, in which it changes to a yellowish chrysalis, resembling that of a beetle; out of which, in the space of about eighteen days, proceeds the perfect insect. This species possesses a considerable degree of elegance, but generally diffuses a very strong and unpleasant smell: it flies with considerable strength and rapidity, and is generally seen on the wing during the hottest part of the day. In many parts of North America is found a variety, differing merely in size, being far larger than the European kind, and measuring an inch and a half in length.

SILPHIUM, a genus of plants belonging to the class of syngenesia, and to the order of polygamia necessaria; and in the natural system arranged under the 49th order, compositæ. The receptacle is paleaceous; the pappus has a two-horned margin, and the calyx is squamose. There are eight species; the laciniatum, terebinthinum, perfoliatum, connatum, asteriscum, trifoliatum, arboreum, and trilobatum. The first six of these are natives of North America.

Several of the silphæ are of an entirely oval outline: of this kind is the S. thoracica, which is easily distinguishable by its red thorax, every other part of the animal being coal-black: it is about half an inch in length.

Silpha atrata is of similar size, but totally black, and has the wing-sheaths marked by three rising lines: its larva, which may be found in gardens, is of a lengthened shape and of a black colour. See Plate Nat. Hist., figs. 361 and 362.

SILVER, in natural history, is a metal of a fine white colour, without either taste or smell; and in point of brilliancy perhaps inferior to none of the metallic bodies, if we except polished steel. Its hardness is 7. When melted, its specific gravity is 10.478; when hammered, 10.609. In malleability, it is inferior to none of the metals, if we except gold, and perhaps also platinum. It may be beaten out into leaves only $\frac{1}{160000}$ inch thick. Its ductility is equally remarkable: it may be drawn out into wire much finer than a human hair; so fine, indeed, that a single grain of silver may be extended about 400 feet in length. Its tenacity is such, that a wire of silver 0.078 inch in diameter is capable of supporting a weight of 187.13lbs. avoirdupois without breaking.

Silver melts when it is heated completely red hot; and while melted, its brilliancy is much increased. According to the calculation of Bergman and Mortimer, its fusing point is 1000° of Fahrenheit. It continues melted at 28° Wedgewood, but requires a greater heat to bring it to fusion. If the heat is increased after the silver is melted, the liquid metal boils, and may be volatilized; but a very strong and long-continued heat is necessary.

When cooled slowly, its surface exhibits the appearance of crystals; and if the liquid part of the metal is poured out as soon as the surface congeals, pretty large crystals of silver may be obtained. By this method Tillet, and Mongez junior, obtained it in four-sided pyramids, both insulated and in groups.

Silver is not oxidated by exposure to the air: it gradually, indeed, loses its lustre, and becomes tarnished; but this is owing to a different cause. Neither is it altered by being kept under water. But if it is kept for a long time melted in an open vessel, it gradually attracts the oxygen from the atmosphere, and is converted into an oxide. Macquer, by exposing silver 20 times successively to the heat of a porcelain furnace, obtained a glass of an olive-green colour. Nay, if the heat is sufficient, the silver even takes fire and burns like other combustible bodies. Van Marum made electric sparks from his powerful Teylerian machine pass through a silver wire; the wire exhibited a greenish-white flame, and was dissipated into smoke. Before a stream of oxygen and hydrogen gas, it burns rapidly with a light-green flame.

The oxide of silver, obtained by means of heat, is of a greenish or yellowish grey colour; and is easily decomposed by the application of heat in close vessels, or even by exposing it to the light. When silver is dissolved in nitric acid, and precipitated by lime water, it falls to the bottom under the form of a powder, of a dark-greenish brown colour. From the experiments of Wenzel and Bergman it follows, that the greenish or yellowish grey oxide is composed of about 90 parts of silver and 10 of oxygen. When this oxide is exposed to the light, part of its oxygen is separated, as Scheele first ascertained; and is converted into a black powder, which contains but a very small portion of oxygen, and may be considered as silver reduced. By exposing the solution of silver in nitric acid to sunshine, the silver precipitates in the form of a flea-brown powder.

Neither carbon nor hydrogen has been combined with silver; but it combines readily with sulphur and phosphorus.

1. When thin plates of silver and sulphur are laid alternately above each other in a crucible, they melt readily in a low red heat, and form sulphuret of silver. It is of a black or very deep violet colour; brittle, but capable of being cut with a knife; often crystallized in small needles; and much more fusible than silver. If sufficient heat is applied, the sulphur is slowly volatilized, and the metal remains behind in a state of purity. It is very difficult to determine the proportion of the ingredients which enter into the composition of this substance, because there is an affinity between silver and its sulphuret, which disposes them to combine together. The greatest quantity of sulphur which a given quantity of silver is capable of taking up, is, according to Wenzel, $\frac{13}{100}$.

It is well known, that when silver is long exposed to the air, especially in frequented places, as churches, theatres, &c. it acquires a covering of a violet colour, which deprives it of its lustre and malleability. This covering, which forms a thin layer, can only be detached from the silver by bending it, or breaking it in pieces with a hammer. It was examined by Mr. Proust, and found to be sulphuret of silver.

2. Silver was first combined with phosphorus by Mr. Pelletier. If one ounce of silver, one ounce of phosphoric glass, and two drams of charcoal, are mixed together, and heated in a crucible, phosphuret of sulphur is formed. It is of a white colour, and appears granulated, or crystallized. It breaks under the hammer, but may be cut with a knife. It is composed of four parts of silver and one of phosphorus. Heat decomposes it by separating the phosphorus. Pelletier has observed, that silver in fusion is capable of combining with more phosphorus than solid silver: for when phosphuret of silver is formed by projecting phosphorus into melted silver, after the crucible is taken from the fire, a quantity of phosphorus is emitted the moment the metal congeals.

Silver does not combine with the simple incombustibles.

Silver combines readily with the greater number of metallic bodies.

1. When silver and gold are kept melted together, they combine, and form an alloy composed, as Homberg ascertained, of one part of silver, and five of gold. He kept equal parts of gold and silver in gentle fusion for a quarter of an hour, and found, on breaking the crucible, two masses, the uppermost of which was pure silver, the undermost the whole gold combined with $\frac{1}{6}$ of silver. Silver, however, may be melted with gold in almost any proportion; and if the proper precautions are employed, the two metals remain combined together.

The alloy of gold and silver is harder and more sonorous than gold. Its hardness is a maximum when the alloy contains two parts of gold and one of silver. The density of these metals is but little increased; but the colour of the gold is much altered, even when the proportion of the silver is small; one part of silver produces a sensible whiteness in twenty parts of gold. The colour is not only pale, but it has also a very sensible greenish tinge, as if the light reflected by the silver passed through a very thin covering of gold. This alloy being more fusible than gold, is employed to solder pieces of that metal together.

2. When silver and platinum are fused together (for which a very strong heat is necessary), they form a mixture, not so ductile as silver, but harder and less white. The two metals are separated by keeping them for some time in the state of fusion; the platinum sinking to the bottom from its weight. This circumstance would induce us to suppose that there is very little affinity between them.

The affinities of silver, and its oxides, are placed by Bergman in the following order:

Silver.	Oxide of Silver.
Lead,	Muriatic acid,
Copper,	Oxalic,
Mercury,	Sulphuric,
Bismuth,	Saclactic,
Tin,	Phosphoric,
Gold,	Sulphurous,
Antimony,	Nitric,
Iron,	Arsenic,
Manganese,	Fluoric,
Zinc,	Tartaric,
Arsenic,	Citric,
Nickel,	Lactic,
Platinum,	Acetic,
Sulphur,	Succinic,
Phosphorus.	Prussic,
	Carbonic.

Silver, *fulminating*. See Fulmination.

Silver-leaf, that beaten out into fine leaves for the use of the gilders, which is performed in the same manner as gold-leaf.

Silver-wire, that drawn out into fine wire; for the manner of doing which, see the articles Gold-wire, and Wire-drawing.

Silver, *shell*, is prepared of the shreds of silver-leaves, or of the leaves themselves, for the use of painters, after the same manner as shell-gold. See Gold.

Silvering. The art of silvering wood, paper, &c. is performed in the same manner as gilding, making use of silver instead of gold leaf.

To silver copper or brass, clean the metal with aqua fortis, by washing it lightly, and then throwing it in water; or by scouring it with salt and tartar with a wire brush. Dissolve some silver in aqua fortis, and put pieces of copper into the solution; this will throw down the silver in a state of metallic powder. Take 20 grains of this powder, and mix with it two drams of tartar, the same quantity of common salt, and half a drachm of alum; rub the articles with this composition till they are perfectly white, then brush it off, and polish them with leather.

To silver the dial-plates of clocks, scales of barometers, &c. Take half an ounce of silver lace, add to it an ounce of double-refined aqua fortis, put them into an earthen pot, and place them over a gentle fire till all is dissolved, which will happen in about five minutes; then take them off, and mix it in a pint of clear water, after which, pour it into another clean vessel, to free it from grit or sediment; then add a spoonful of common salt; and the acid, which has now a green tinge, will immediately let go the silver particles, which form themselves into a white curd; pour off the acid, and mix the curd with two ounces of salt of tartar, half an ounce of whiting, and a large spoonful of salt, more or less, according as you find it for strength. Mix it well up together, and it is ready for use.

Having well cleared the brass from scratches, rub it over with a piece of old hat and rottenstone, to clear it from all greasiness, and then rub it with salt and water with your hand: take a little of the beforementioned composition on your finger, and rub it over where the salt has touched, and it will adhere to the brass, and completely silver it. After which, wash it well with water, to take off what aqua fortis may remain in the composition; when dry, rub it with a clean rag, and give it one or two coats of varnish. This silvering is not durable, but may be improved by heating the article, and repeating the operation till the covering seems sufficiently thick.

Silver plating. The coat of silver applied to the surface of the copper by the means mentioned above, is very thin, and is not durable. A more substantial method of doing it is as follows: Form small pieces of silver and copper, and tie them together with wire, putting a little borax between. The proportion of silver may be to that of copper, as 1 to 12. Put them into a white heat, when the silver will be firmly fixed to the copper. The whole is now made to pass between rollers till it is of the required thickness for manufacturing the articles required.

SILURUS, a genus of fishes of the order abdominales. The generic character is, head large, depressed; mouth wide, bearded by long tentacula; body lengthened, naked; first ray of the pectoral fins, or of the first dorsal fin, toothed backwards. There are 28 species.

1. Silurus glaris, European silure. The great or common silure may perhaps be considered as the largest of all European river-fishes; growing to the length of eight, ten, or even fifteen feet, and to the weight of three hundred pounds. Its more general length, however, is from two to three or four feet. The head is broad and depressed; the body thick and of a lengthened form, with the abdomen very thick and short. It is a fish of a remarkably inert or sluggish disposition, being rarely observed in motion, and commonly lying half-imbedded in the soft bottom of the rivers it frequents, under the projecting roots of trees, rocks, logs, or other substances. In this situation it remains, with its wide mouth half-open, gently moving about the long cirri or tentacula situated on each side the jaws; which the smaller fishes mistaking for worms, and attempting to seize, become a ready prey to the sluggish silure. The usual colour of this species is dark olive, varied with irregular spots of black; the abdomen and lips being of a pale flesh colour, and the fins tinged with violet. It is an inhabitant of the larger rivers of Europe, as well as some parts of Asia and Africa; but appears to be most plentiful in the north of Europe. It is in no very high estimation as a food, the flesh being of a somewhat glutinous nature; but, from its cheapness, is in much request among the inferior ranks, and is eaten either fresh or salted: the skin also, which is smooth, and destitute of apparent scales, is dried and stretched, and after rubbing with oil, becomes of a horny transparency and strength, and is used in some of the northern regions instead of glass for windows. The silure is not a very prolific fish; depositing but a small quantity of spawn, consisting of large globules or ova: these, as well as the newly hatched young, are frequently the prey of other fishes, frogs, &c. and thus the great increase of the species is prevented. The ova, according to Dr. Bloch, usually hatch in the space of seven or nine days from their exclusion.

2. Silurus electricus, electric silure. Length about twenty inches; head and fore-parts very broad and depressed; on the upper lip two cirri; on the lower four; teeth small and numerous. Native of the African rivers; observed by Forskal in the Nile: possesses a degree of electric or galvanic power, but in a much slighter degree than the torpedo.

3. Silurus catus, cat silure. Length about two feet; form rounded and thick; colour dusky above, pale flesh-colour beneath; head round; mouth very large; on the upper jaw, beneath each eye, a very long beard; on the lower jaw four short beards; first dorsal fin small and conic; second, or adipose fin, without rays; rest of the fins small and red; tail forked. Inhabits the sea and rivers of North America, preying on all kinds of smaller fishes; and not sparing even those of its own kind: in taste resembles an eel, and is much esteemed by the Americans: is a fish of slow motion, like the European silure.

4. Silurus costatus is an inhabitant of South America and India. See Plate Nat. Hist. fig. 360.

SIMIA, ape, a genus of quadrupeds of the order primates. The Linnæan generic character is, front teeth in each jaw four, placed near together; canine teeth solitary, longer than the others, distant from the remaining teeth, or grinders; grinders obtuse. This numerous race may be properly divided into four sections, of which there are about 70 species, viz. 1. Apes, or such as are destitute of a tail. 2. Baboons, or such as have very muscular bodies, and whose tails are commonly short. 4. Monkeys, whose tails are, in general, long: and, lastly, sapajous, or monkeys, with what are termed prehensile tails, viz. such as can, at pleasure, be twisted round any object, so as to answer the purpose of an additional hand to the animal.

Of the whole genus, or the monkey tribe in general, it may be observed, that the baboons are commonly of a ferocious and sullen disposition. The larger apes are also of a malignant temper, except the oran otan and the gibbons. The monkeys, properly so called, are very various in their dispositions; some of the smaller species are lively, harmless, and entertaining; while others are as remarkable for the mischievous malignity of their temper, and the capricious uncertainty of their manners.

It may not be improper here to observe, that it is no easy task to determine with exact precision the several species of this extensive genus; since, exclusive of the varieties in point of colour, they are often so nearly allied as to make it difficult to give real distinctive characters. The most remarkable species are,

Apes.

1. Simia satyrus, oran otan. Of these singular animals, the species which has most excited the attention of mankind is, the oran otan, or, as it is sometimes called, the satyr, great ape, or man of the woods. It is a native of the warmer parts of Africa and India, as well as of some of the Indian islands, where it resides principally in woods, and is supposed to feed, like most others of this genus, on fruits. The oran otan appears to admit of considerable variety in point of colour, size, and proportions; and there is reason to believe, that, in reality, there may be two or three kinds, which, though nearly approximated as to general similitude, are yet specifically distinct. The specimens imported into Europe have rarely exceeded the height of two or three feet, and were supposed to be young animals; but it is said that the full-grown ones are, at least, six feet in height. The general colour seems to be dusky or brown; in some ferruginous or reddish brown, and in others coal-black, with the skin itself white. The face is bare; the ears, hands, and feet, nearly similar to the human, and the whole appearance such as to exhibit the most striking approximation to the human figure. The likeness, however, is only a general one; and the structure of the hands and feet, when examined with anatomical exactness, seems to prove, in the opinion of those most capable of judging with accuracy on the subject, that the animal was principally designed by nature for the quadrupedal manner of walking, and not for an upright posture, which is only occasionally assumed, and which, in those exhibited to the public, is, perhaps, rather owing to instruction than truly natural. The count de Buffon, indeed, makes it one of the distinctive characters of the real or proper apes (among which the oran otan is the chief), to walk erect on two legs only; and it must be granted, that these animals support an upright position much more easily and readily than most other quadrupeds, and may probably be very often seen in this attitude even in a state of nature.

The manners of the oran otan, when in captivity, are gentle, and perfectly void of that disgusting ferocity so conspicuous in some of the larger baboons and monkeys. It is docile, and may be taught to perform, with dexterity, a variety of actions in domestic life. Thus it has been seen to sit at table, and, in its manner of feeding and general behaviour, to imitate the company in which it is placed: to pour out tea, and drink it, without aukwardness or constraint; to prepare its bed with great exactness, and compose itself to sleep in a proper manner. Such are the actions recorded of one which was exhibited in London in the year 1738; and the count de Buffon relates nearly similar particulars of that which he saw at Paris. Dr. Tyson, who, about the close of the last century, gave a very exact description of a young oran otan, then exhibited in the metropolis, assures us, that, in many of its actions, it seemed to display a very high degree of sagacity. "The most gentle and loving creature that could be. Those that he knew a ship-board he would come and embrace with the greatest tenderness, opening their bosoms, and clasping his hands about them; and, as I was informed, though there were monkeys aboard, yet it was observed he would never associate with them, and, as if nothing akin to them, would always avoid their company."

But however docile and gentle when taken young, and instructed in its behaviour, it is said to be possessed of great ferocity in its native state, and is considered as a dangerous animal, capable of readily overpowering the strongest man. Its swiftness is equal to its strength, and for this reason it is rarely to be obtained in its full-grown state; the young alone being taken. A few years past, the hand of a supposed full-grown oran otan was brought from Sierra Leona, which, from its size, seemed to justify the idea of the stature to which this species is supposed to grow: it was of a black colour, and consequently belonged to the black variety of this species, or that described in a young state by Dr. Tyson.

M. Vosmaer's account of the manners of an oran otan brought into Holland in the year 1776, and presented to the prince of Orange's menagerie, is so curious and satisfactory, that we shall extract it from his accurate publication on that subject.

This animal was a female: its height was about two Rhenish feet and a half. It shewed no symptoms of fierceness or malignity, and was even of a somewhat melancholy appearance. It was fond of being in company, and shewed a preference to those who took daily care of it, of which it seemed to be sensible. Often when they retired it would throw itself on the ground, as if in despair, uttering lamentable cries, and tearing in pieces the linen within its reach. Its keeper having sometimes been accustomed to sit near it on the ground, it took the hay of its bed, and laid it by its side, and seemed, by every demonstration, to invite him to be seated near. Its usual manner of walking was on all-fours, like other apes; but it could also walk on its two hind feet only. One morning it got unchained, and we beheld it with wonderful agility ascend the beams and rafters of the building: it was not without some pains that it was retaken, and we then remarked an extraordinary muscular power in the animal; the assistance of four men being necessary, in order to hold it in such a manner as to be properly secured. During its state of liberty it had, amongst other things, taken the cork from a bottle containing some Malaga wine, which it drank to the last drop, and had set the bottle in its place again. It ate almost every thing which was given it; but its chief food was bread, roots, and especially carrots; all sorts of fruits, especially strawberries; and appeared extremely fond of aromatic plants, as parsley and its root. It also ate meat, both boiled and roasted, as well as fish. It was not observed to hunt for insects like other monkeys; it was fond of eggs, which it broke with its teeth and sucked completely; but fish and roast meat seemed its favourite food. It had been taught to eat with a spoon and a fork. When presented with strawberries on a plate, it was extremely pleasant to see the animal take them up, one by one, with a fork, and put them into its mouth, holding, at the same time, the plate in the other hand. Its common drink was water; but it also very willingly drank all sorts of wine, and particularly Malaga. After drinking it wiped its lips, and after eating, if presented with a tooth-pick, would use it in a proper manner. I was assured, that on shipboard it ran freely about the vessel, played with the sailors, and would go, like them, into the kitchen for its mess. At the approach of night it would lie down to sleep; and prepared its bed by shaking well the hay on which it slept, and putting it in proper order, and, lastly, covering itself warm with the coverlet. One day, seeing the padlock of its chain opened with a key, and shut again, it seized a little bit of stick, and put it into the key-hole, turning it about in all directions, endeavouring to see whether the padlock would open or not. This animal lived seven months in Holland. On its first arrival it had but very little hair, except on its back and arms: but on the approach of winter it became extremely well covered; the hair on the back being three inches in length. The whole animal then appeared of a chesnut-colour; the skin of the face, &c. was of a mouse-colour, but about the eyes and round the mouth of a dull flesh-colour.

It came from the island of Borneo, and was deposited in the museum of the prince of Orange.

Upon the whole, it appears clearly that there are two distinct species of this animal, viz. the pongo, or great black oran otan, which is a native of Africa, and the reddish brown or chesnut oran otan, called the jocko, which is a native of Borneo and some other Indian islands. This latter, as appears from a collation of most of the specimens which have been surveyed with the necessary degree of exactness, is distinguished by having no nails on the great toes; whereas in the pongo, or black species, they are conspicuous.

2. Simia lar, or long-armed ape. This is a species of a more deformed appearance than the oran otan, and is distinguished by the excessive length of its arms, which, when the animal stands upright, are capable of touching the ground with the fingers. It is a native of India and some of the Indian islands, and grows to the height of four feet or more. Its colour is black; but the face is commonly surrounded by a whitish beard.

Notwithstanding the apparent ferocity of the gibbon, and the deformity of its figure, it is of a more tractable and gentle nature than most of its tribe, and has even been celebrated for the decorum and modesty of its behaviour. Considered with respect to the rest of the genus it ranks among the genuine apes, or those which have not the least vestige of a tail; and like the oran otan, alarms the pride of mankind by too near an approach to the real primates of the creation. Nay, Linnæus, in his description, actually places it in the genus homo, under the title of homo lar.

3. Simia sylvanus, pigmy. This is the smallest of the genuine apes, or those destitute of tails. In its general appearance, as well as in colour, it extremely resembles the Barbary ape; but is not larger than a cat, and has a rounder or flatter face than the Barbary ape. This is supposed, by Mr. Pennant, to have been the pigmy of the antients, which was said to wage war, at certain seasons, with the cranes. It is a native of Ethiopia, where it is most common; but it is also found in other parts of Africa. It is easily tamed, and is much more docile and gentle than the former species.

BABOONS.

4. Simia sphinax, common baboon. This is a species of very considerable size, and when in a sitting posture, is from three to four feet in height. It is extremely strong and muscular in its upper parts, and slender towards the middle; but this is the general shape of all the true baboons; its colour is an uniform greyish-brown, paler beneath; the hairs on the upper parts, if narrowly inspected, appear as if mottled; the face is long, and of a tawny flesh-colour; the eyes appear as if sunk into the head, or very deeply seated, and are of a hazel colour. The hands and feet have strong blunt claws; but the thumbs of the hands have rounded nails. The tail is very short. It is ferocious in its manners, and its appearance is at once grotesque and formidable. The region surrounding the tail, to a considerable distance on each side, is perfectly bare and callous, and of a red colour. This is also common, in a greater or smaller degree, to the rest of this division. It is a native of the island of Borneo.

5. Simia mormon, variegated baboood. This is at least equal in size, if not superior, to the former, and, when in an upright posture, is about five feet high. It is the most remarkable of the whole genus for brilliancy and variety of colour. The general tinge is a rich and very deep yellowish-brown; the hairs, if viewed near, appearing speckled with yellow and black. The form of the face is long, with the snout ending somewhat abruptly; the whole length of the nose, down the middle, is of a deep blood-red; but the parts on each side are of a fine violet-blue, deeply marked by several oblique furrows. The remainder of the face is of a pale whitish-yellow. It is a native of the interior parts of Africa; but it is said to have been also brought from India.

The variegated baboon is of a fierce disposition, and extremely muscular and strong. Its voice somewhat resembles the slight roar of a lion: it is a rare species, and is not often imported into Europe.

6. Simia maimon, maimon. The synonyms between this species and the former are commonly confounded. It is described by the count de Buffon under the name of mandrill. It is an active animal, and seems far less indocile and malignant than the rest of the baboons. The general likeness which it bears to the former species is such as to give the idea of the same animal in a less advanced state of growth, and with less brilliant colours; the nose, instead of being red on its upper part, is merely flesh-coloured; but the sides are blue and furrowed, as in the former species. This baboon is not uncommon in exhibitions of animals. Its length from nose to tail is about two feet. Tail exactly as in the former.

The next division of the baboons consists of such as have long tails. Of these the chief is the

7. Simia hamadryas, dog-faced baboon. This species is of an elegant colour, composed of a mixture of grey and brown, the hair appearing as if speckled. It is a very large animal, at least equal, if not superior, in size to the common brown baboon and the mormon. It is remarkable for a vast quantity of flowing hair on each side the head, as well as round the shoulders, spreading in such a manner as to give the appearance of a short cloak or mantle. The whole face is naked, and of a flesh-colour, more or less deep in different individuals. The tail is almost the length of the body, aud is commonly a little tufted at the end. The nails on the hands or fore-feet are flat; those on the hind-feet resemble strong claws. This is a rare species in comparison with the common baboon, and is a native of the hottest parts of Africa and Asia, where it is said to reside in vast troops, and to be very fierce and dangerous. There is a wonderful degree of sagacity in the coun-

tenance of this animal, and a kind of solemn contemplative disposition seems to be strongly indicated in its looks, when calm and undisturbed; but when irritated, the most striking efforts of vindictive violence are immediately exhibited. It is also possessed of an uncommon degree of obstinate moroseness, surpassing most others of its tribe, and is, when in a state of confinement, of a disposition so rude and unquiet, and of manners so peculiarly indecorous, as generally to frustrate all attempts to civilize and reclaim it."

MONKEYS.

8. Simia leonina. Leonine monkey. This species was described from the living animal in the possession of the duc de Bouillon; and was in the royal menagerie at Versailles, in the year 1775. Its length was two feet from nose to tail, and it was eighteen inches high when standing on all-fours. The legs were long in proportion to the body; the face naked and quite black; the whole body and limbs of the same colour; the hair, though long, appearing short, on account of its lying smooth: around the face, according to Buffon's figure, is a fine long chevelure of grey-brown hair, and a large beard of fair grey. The chevelure or spreading hair round the face stretches upwards over the eyes and forehead, so as to encircle the whole head in a remarkable manner, as in the ouanderou or lion-tailed baboon, to which indeed, from the figure as well as description, it appears so extremely similar, that it might well pass for a variety of that animal.

9. S. Diana. Spotted monkey. Mr. Pennant describes this species as of a middling size, and of a reddish colour on the upper parts, as if singed, and marked with white specks; the belly and chin whitish; the tail very long. The Linnæan description differs. Linnæus says the animal is of the size of a large cat, and is black, spotted with white; the hind part of the back ferruginous; the face black; from the top of the nose a white line, passing over each eye to the ears in an arched direction; (this circumstance was probably the reason of the Linnæan name Diana, by which he has chosen to distinguish the animal) the beard pointed, black above, white beneath, and placed on a kind of fatty tumor; breast and throat white; from the rump across the thighs a white line; tail long, straight, and black; ears and feet of the same colour; canine teeth large. See Plate Nat. Hist. fig. 363.

10. Simia nasuta. Long-nosed monkey. Two remarkable monkeys are represented in Mr. Pennant's History of Quadrupeds, from drawings by a Mr. Paillou. The one is called the long-nosed monkey; it has a very long and slender nose, covered with a flesh-coloured skin; the hair on the forehead falls back; on the body and breast it is long; the colour of the head and upper parts is pale ferruginous mixed with black; of the breast and belly light ash-colour; tail very long; height when sitting down about two feet. Native country uncertain: probably Africa. Its face has very much the appearance of a long-nosed dog. See Plate Nat. Hist. fig. 364.

The other is called by Mr. Pennant the prude monkey; and of this he gives no particular description.

11. S. sinica. Chinese monkey. The Chinese monkey, so named from the unusual disposition of the hair on the top of the head, which spreads out in a circular direction, somewhat in the manner of a Chinese cap, is a native of Ceylon, and is about the size of a cat. Its general colour is a pale yellowish-brown, palest on the under parts. The face is commonly dusky, and sometimes the general tinge of the animal is dusky-ferruginous. This is a species easily distinguished when seen in a healthy state: the hair on the top of the head resembling that of a boy; as if parted in the middle, and lying smooth over the head. They are said to inhabit the woods in great troops, and to be very destructive to such gardens and plantations as lie within reach of their settlements. The tail in this species is very long: the nails of the thumbs are round; the rest long.

12. S. petaurista. Vaulting monkey. This is described by Mr. Allamand in his edition of Buffon's Natural History of Quadrupeds. It is said to be somewhat more than a foot high, and the tail about twenty inches long. The upper parts of the animal are of a dark olivaceous colour, owing to a mixture of olive-green and black hair; the face black, with a snow-white triangular spot on the nose; the chin, throat, breast, and belly, white; the under part of the tail and insides of the limbs of a blackish grey. It is a most extremely nimble and active animal, according to M. Allamand. The individual in his possession came from Guinea. It was perfectly familiar, playful, of a gentle disposition, and so rapid in its motions that it seemed to fly rather than leap.

13. Simia mona. Varied monkey. This is said to be the species which gives the name of monkey to the whole tribe: from the African word moane; or rather, as Mr. Pennant surmises, from its corruption monichus. It is one of the largest species, being about a foot and a half in length, with a tail nearly two feet long. The nose, mouth, and spaces round the eyes, are of a dull flesh-colour; the cheeks are bounded by long whitish hairs inclining to yellow; the forehead is grey, and above the eyes, from ear to ear, extends a black line. The upper part of the body is dusky and tawny; the breast, belly, and inside of the limbs, white; the outside of the thighs and arms black; hands and feet black and naked: the tail of a cinereous brown. On each side the base of the tail is commonly an oval white spot. This species inhabits Barbary, Æthiopia, and other parts of Africa.

14. Simia nasalis. Proboscis monkey. Amongst the whole tribe of monkeys this perhaps may be considered as the most singular in its aspect; the nose being of such a length and form as to present, especially in a profile view, an appearance the most grotesque imaginable; and indeed from an inspection of the figure alone, one would be apt to imagine that it must have been designed for a caricature of a monkey. The animal, however, is preserved in the royal cabinet at Paris, and was first described by Mons. D'Aubenton. It is a large species, measuring two feet from the tip of the nose to the tail, which is more than two feet long. The face has a kind of curved form, and is of a brown colour, and marked with blue and red; the ears broad, thin, naked, and hid within the hair. The form of the nose is most singular, being divided almost into two lobes at the tip; a longitudinal furrow running along the middle. It is said to be found chiefly in Cochinchina, and to grow to a very large size. It is sometimes seen in great troops, and is considered as of a ferocious disposition. It feeds only on fruits. Its native name is khî dôc, or great monkey.

15. Simia nemæus. Cochinchina monkey. The douc or Cochinchina monkey is a very large species, measuring at least two feet from the nose to the tail. The face is flattish and of a yellowish-bay colour, as are also the ears; across the forehead runs a narrow dusky band. The back, the under parts of the body, and sides, are of a yellowish grey; the lower part of the arms and tail are white; the feet dusky. It is a native of Cochinchina, and also of Madagascar. It is said that a bezoar is more frequently found in the stomach of this species than of almost any other. When in an upright posture this animal measures three and a half or four feet in height, being nearly of the size of a Barbary ape. This species seems considerably allied in its general form and colours to the preceding, but differs greatly in the form of the face. See Plate Nat. Hist. fig. 365.

16. Simia rosalia. Silky monkey. This species is so named from the appearance of its hair, which is very fine, soft, long, and of a bright-yellow colour, resembling yellow silk. Round the face the hair is much longer than in other parts, so as to form a large mane like that of a lion; near the face this mane is of a reddish colour, and grows paler as it recedes from the cheeks; the face itself is of a dusky purple; the ears round and naked; the hands and feet are also naked, and of the same dull purple colour as the face; the claws are small and sharp; the tail is very long, and rather bushy at the extremity. It is a native of Guiana, and is a lively, active species, and gentle in a state of confinement. See Plate Nat. Hist. fig. 366.

SEPAJOUS.

17. Simia beelzebul. Preacher monkey. This species is said to be of the size of a fox, and of a black colour, with smooth glossy hair; round beard beneath the chin and throat; the feet and end of the tail brown. It is a native of Brasil and Guiana, inhabiting the woods in vast numbers, and howls in a dreadful manner. Marcgrave assures us, that one sometimes mounts the top of a branch, and assembles a multitude below; he then sets up a howl so loud and horrible, that a person at a distance would imagine that a hundred joined in the cry; after a certain space he gives a signal with his hand, when the whole assembly join in chorus; but on another signal a sudden silence prevails and then the orator finishes his harangue. This howling faculty is owing to the conformation of the os hyoides, or throat-bone, which is dilated into a bottle-shaped concavity.

18. Simia paniscus. Four-fingered monkey. This animal is distinguished by the gracility of its body and limbs; its uniform black colour, except on the face, which is of a dark flesh-colour; and by the want of thumbs on the fore feet, instead of which are very small projections or appendices. It is one of the most active and lively of animals, and is besides of a gentle and tractable disposition in a state of confinement. It inhabits the woods of South America; associating in great multi-

tudes; assailing such travellers as pass through their haunts with an infinite number of sportive and mischievous gambols; chattering and throwing down dry sticks, swinging by their tails from the boughs, and endeavouring to intimidate the passengers by a variety of menacing gestures.

SIMILAR, in arithmetic and geometry, the same with like. In mathematics, similar parts have the same ratio to their wholes; and if the wholes have the same ratio to the parts, the parts are similar. Similar angles are also equal angles. In solid angles, when the planes under which they are contained are equal, both in number and magnitude, and are disposed in the same order, they are similar, and consequently equal. Similar arches of a circle are such as are like parts of their whole circumferences, and consequently equal. Similar plane numbers are those numbers which may be ranged into the form of similar rectangles, that is, into rectangles whose sides are proportional; such are 12 and 48, for the sides of 12 are 6 and 2, and the sides of 48 are 12 and 4; but 6 : 2 : : 12 : 4, and therefore those numbers are similar. Similar polygons are such as have their angles severally equal, and the sides about those angles proportional. Similar rectangles are those which have their sides about the equal angles proportional. Hence, 1. All squares are similar rectangles. 2. All similar rectangles are to each other as the squares of their homologous sides. Similar right-lined figures are such as have equal angles, and the sides about those equal angles proportional. Similar segments of a circle are such as contain equal angles. Similar curves: two segments of two curves are called similar, if, any right-lined figure being inscribed within one of them, we can inscribe always a similar right-lined figure in the other. Similar conic sections: two conic sections are said to be similar, when any segment being taken in the one, we can assign always a similar segment in the other. Similar diameters of two conic sections: the diameters in two conic sections are said to be similar, when they make the same angles with their ordinates. Similar solids are such as are contained under equal numbers of similar planes alike situated. Similar triangles are such as have their three angles respectively equal to one another. Hence, 1. All similar triangles have the sides about their angles proportional. 2. All similar triangles are to one another as the squares of their homologous sides.

SIMILAR FIGURES, in geometry, such as have their angles respectively equal, and the sides about the equal angles proportional.

SIMONIANS, in church history, a sect of antient christians, so called from their founder, Simon Magus, or the magician. The heresies of Simon Magus were principally his pretending to be the great power of God, and thinking that the gifts of the Holy Ghost were venal.

SIMONY, is the corrupt presentation of any one to an ecclesiastical benefice, for money, gift, reward, or benefit.

By one of the canons of 1603, every person before his admission to any ecclesiastical promotion, shall, before the ordinary, take an oath, that he has made no simoniacal contract, promise, or payment, directly or indirectly, by himself or any other, for the obtaining of the said promotion; and that he will not afterwards perform or satisfy any such kind of payment, contract, or promise, by any other without his knowledge or consent.

To purchase a presentation, the living being actually vacant, is open and notorious simony; this being expressly in the face of the statute. Moor. 914.

The sale of an advowson, during a vacancy, is not within the statute of simony, as the sale of the next presentation is; but it is void by the common law. 2 Black. 22.

A bond of resignation is a bond given by the person intended to be presented to a benefice, with condition to resign the same, and is special or general. The condition of a special one is to resign the benefice in favour of some certain person, as a son, kinsman, or friend of the patron, when he shall be capable of taking the same. By a general bond, the incumbent is bound to resign on the request of the patron. 4 Bac. Abr. 470.

A bond with condition to resign within three months after being requested, to the intent that the patron might present his son when he should be capable, was held good; and the judgment was affirmed in the exchequer-chamber; for a man may, without any colour of simony, bind himself for good reasons, as if he takes a second benefice, or if he is non-resident, or that the patron presents his son, to resign; but if the condition had been to let the patron have a lease of the glebe or tithes, or to pay a sum of money, it would have been simoniacal.

SIMOOM. A wind or haze was observed by Mr. Bruce, in the course of his travels to discover the sources of the Nile, which is supposed to be in some respects analogous to the sirocco. It is called by Mr. Bruce the simoom, and from its effects upon the lungs, we can entertain but little doubt, that it consists chiefly of carbonic acid gas in a very dense state, and perhaps mixed with some other noxious exhalations.

In the same desert Mr. Bruce observed the astonishing phenomenon of moving pillars of sand, which are probably the effects of a number of whirlwinds in those torrid regions. As the description of these pillars is in some degree blended with that of the simoom, we shall extract the passage. In relating the particulars of his journey across a certain part of the deserts of Africa, Mr. Bruce observes, "We were here at once surprised and terrified by a sight surely one of the most magnificent in the world. In that vast expanse of desert, from west and to the north-west of us, we saw a number of prodigious pillars of sand at different distances, at times moving with great celerity, and at others stalking on with a majestic slowness; at intervals we thought they were coming in a very few minutes to overwhelm us; and small quantities of sand did actually more than once reach us. Again they would retreat so as to be almost out of sight, their tops reaching to the very clouds. There the tops often separated from the bodies; and these, once disjoined, dispersed in the air, and did not appear more. Sometimes they were broken near the middle, as if struck with a large cannon-shot. About noon they began to advance with considerable swiftness upon us, the wind being very strong at north. Eleven of them ranged alongside of us about the distance of three miles. The greatest diameter of the largest appeared to me at that distance as if it would measure ten feet. They retired from us with a wind at south-east, leaving an impression upon my mind to which I can give no name, though surely one ingredient in it was fear, with a considerable deal of wonder and astonishment. It was in vain to think of flying; the swiftest horse, or fastest-sailing ship, could be of no use to carry us out of this danger; and the full persuasion of this rivetted me as if to the spot where I stood, and let the camels gain on me so much in my state of lameness, that it was with some difficulty I could overtake them."

SIMPLE, in music, a term applied to that counterpoint in which note is set against note, and which is called simple, in opposition to more elaborate composition, known by the name of figurative counterpoint. Simple fugue, or simple imitation, is that style of composition in which a single subject is adopted, or some partial echo preserved amongst the several parts. This word in the music of the last age is frequently used in contradistinction to double, applied to variations, as double 1, double 2, &c. and signifies the plain motivo, or subject, on which the variations are founded. Simple cadence is that in which the notes are equal through all the parts. Simple concords are those wherein we hear only two notes in consonance; and simple intervals are those in which no parts or divisions are supposed, and which the antients Greeks called diastems.

SIMPLE SOUND, a pure, unmixed, single sound. Some theorists will not allow that there is, musically speaking, any such sound in nature; but assert on the contrary that every sound which is produced is at least accompanied with its twelfth and seventeenth.

SIMPLE, in pharmacy, a general name given to all herbs or plants, as having each its particular virtue, whereby it becomes a simple remedy.

SIMPLE SUBSTANCES. See ELEMENTS.

SIMPLICITY, in composition, a natural unadorned melody, or incomplex combination of parts, in which the composer endeavours, rather by the force of his genius and feeling than the refinement of science, to awaken the softer passions, or rouse the mind to ardour. In performance, simplicity is that chaste, unaffected style, which, rejecting all vain and unmeaning flourish, only aims at conveying the ideas of the composer, without disturbing the purity of the text.

SINAPIS, *mustard*, a genus of plants belonging to the class of tetradynamia, and to the order of siliquosa, and in the natural system ranged under the 39th order, siliquosæ. The calyx consists of four expanding strap-shaped deciduous leaves; the ungues or bases of the petals are straight; two glandules between the shorter stamina and pistillum, also between the longer and the calyx. There are 19 species, three of them natives of Britain. 1. The alba, or white mustard, which is generally cultivated as a salad-herb for winter and spring use. 2. The nigra, or common mustard, which is frequently found growing naturally in many parts of Britain, but is also cultivated in fields for the seeds, of which the sauce called mustard is made. 3. The arvensis grows naturally on arable land in many parts of Britain. The seed of this is commonly sold under the title of Durham mustard seed. Of this there are two varieties, if not distinct species; the one with cut, the other with entire, leaves.

Mustard, by its pungency, stimulates the solids; and hence is recommended for exciting appetite, assisting digestion, promoting the fluid secretions, and for the other purposes of the acrid plants called antiscorbutic. It imparts its taste and smell in perfection to aqueous liquors, and by distillation with water yields an essential oil of great acrimony. To rectified spirit its seeds give out very little either of their smell or taste. Subjected to the press, they yield a considerable quantity of mild insipid oil, which is as free from acrimony as that of almonds. They are applied as an external stimulant to benumbed or paralytic limbs; to parts affected with fixed rheumatic pains, and to the soles of the feet, in the low stage of acute diseases, for raising the pulse: in this intention, a mixture of equal parts of the powdered seeds and crumb of bread, with the addition sometimes of a little bruised garlic, is made into a cataplasm with a sufficient quantity of vinegar.

SINAPISM. See PHARMACY.

SINCIPUT, in anatomy, the fore part of the head, reaching from the forehead to the coronal suture.

SINE, or *right sine of an arch*. See TRIGONOMETRY.

SINE-CURE, is where a rector of a parish has a vicar under him endowed and charged with the cure, so that the rector is not obliged either to do duty or residence.

SINE-DIE, *without day*, in law, a term frequently used in our proceedings at common law; as when judgment is given against the plaintiff, he is said to be in misericordia pro falso clamore suo; so when judgment passes for the defendant, it is entered eat inde sine die, being as much as to say, he is discharged, or dismissed the court.

SINISTER. See HERALDRY.

SINKING FUND, in political economy, a portion of the public revenue appropriated to the reduction or discharge of the public debts. As the funding system had been adopted in other countries long before it was resorted to in Great Britain, a provision of this kind had appeared necessary at a much earlier period, and had been established in Holland in 1655, and in the ecclesiastical state in 1685. These funds were both formed by reducing the interest payable on the public debts, and appropriating the annual sum thus saved to the gradual discharge of the principal.

In the reign of king William, when the mode of providing for extraordinary expences by incurring public debts, which has become so general, was first adopted in this country, the particular tax on which money was borrowed, generally produced much more than sufficient to pay the annual interest, and the surplus was applied in sinking or discharging the principal, which was generally effected in a few years. Had this plan been pursued, there never could have been any very great accumulation of public debts; but, as the expenditure increased, and the necessity of loans of still greater amount became more frequent, it was found sufficiently difficult to provide effectually for the yearly interest of the sums thus borrowed; and the repayment of the principal was either put off to a distant period, or left without any provision to the chance of more flourishing times.

Some of the effects of an accumulating public debt soon became evident in the discount at which all government securities sold, and in the difficulties experienced in providing for the annual expenditure; the propriety of reducing, and even of wholly discharging, the debt, was generally acknowledged; and the plan of a sinking fund very similar to that which was afterwards adopted, was recommended in a pamphlet published in 1701. In 1713 Mr. Archibald Hutcheson presented to George I. a plan for payment of the public debts. In 1715 different projects for this purpose were published by Edward Leigh, Mr. Asgill, and others. And in 1717 a plan for the gradual discharge of the debt was actually adopted, which was afterwards generally known by the appellation of the sinking fund.

The country had been engaged in an expensive war during nearly the whole of the reign of queen Anne; and it had been found impracticable to obtain the large sums required, without paying, in most instances, a very high interest; but upon the return of peace the current rate of interest lowered considerably, which proceeded in part from a real increase of the national capital, as well as from loans to government of any great amount being no longer necessary. It was therefore deemed a proper opportunity for effecting a reduction of the high interest payable to the public creditors, and of establishing an effectual plan for reducing by degrees the debts of the nation. Accordingly, on the 20th of May, 1717, general Stanhope, who was then first lord of the treasury, and chancellor of the exchequer, submitted to parliament the terms of a proposed agreement with the bank of England and the South Sea company, by which the interest was to be reduced from 6 to 5 per cent. on the capitals of these corporations, who were the principal public creditors, and who were likewise to furnish money, if it should be necessary, for paying off such individuals as should not agree to a similar reduction of the interest payable to them. The total annual interest saved to government by this transaction was no less than 328,560*l*. 13*s*. 7¼*d*.

The different funds on which most of the public debts had been charged were consolidated; and the produce of all the permanent taxes was distinguished into only three funds, called the aggregate fund, the South Sea fund, and the general fund. From these three funds the interest of all the public debts was payable; and the excess or overplus beyond the payments with which each fund was charged, was to be "appropriated, reserved, and applied, to and for discharging the principal and interest of such national debts and incumbrances, as were incurred before the 25th day of December 1716, and are declared to be national debts, and were provided for by act or acts of parliament, to be discharged therewith, or out of the same, and to or for none other use, intent, or purpose, whatsoever." This constituted the sinking fund; and as the plan originated while sir Robert Walpole was in office, he claimed much honour as the father of it; but it is evident that it required no invention, and but little judgment, to adopt a measure which had been found efficacious in other countries, which had been publicly recommended some years before, and the utility of which was so obvious, that not to have adopted it, when the reduction of interest rendered it so practicable, and when an example had been set in the establishment of the aggregate fund, would have been inexcusable. It was, in fact, nothing more than appropriating generally the surpluses of funds which were before established, to the uses to which the greater part had before been specifically appropriated.

For a few years the fund was strictly applied to the purposes for which it was established; and so well were its nature and importance then understood, that rather than encroach upon it, money was at the same time borrowed for extraordinary expences. This perseverance was however of no long duration; in 1722 it was made a collateral security for the interest of a million raised by exchequer bills, which prepared the way for more direct encroachments. In 1724 the sum of 15,144*l*. 19*s*. was taken from the fund, to make good the loss to the treasury from the reduction of the value of gold coin; and within twelve years from its establishment it was charged with the interest of new loans. In 1733 the gross sum of half a million was taken from it towards the supplies, at which time the medium annual produce of the fund for five years had been 1,212,000*l*. This amount, with its proper increase, would have been amply sufficient for the discharge of the debt which then existed, but the alienation of it was continued; and Dr. Price has shewn that no greater part of the public debt than about eight millions and a half was discharged by the fund from this period to the year 1786; when, in consequence of a new arrangement of the public accounts, the distinction of the different funds above-mentioned was abolished, and the produce of all the permanent taxes included under one general head, called the consolidated fund.

One of the objects of this arrangement was to lay the foundation of a new sinking fund, formed from the general surplus of the revenue, and consisting, like the old fund, in the application of the principle of compound interest. Among those whom Mr. Pitt consulted on this occasion, he particularly sought the advice and assistance of the late Dr. Price, who communicated three plans, which he conceived to be best adapted for carrying into execution a measure that he had so often urged in his different publications, particularly before the American war had swelled the public debts to what then appeared to be a hopeless magnitude: it was one of the plans thus communicated, which was afterwards adopted, but with some alterations which considerably affected its efficacy, and which it has since been found necessary to correct. By the act which was passed for carrying this scheme into execution, 26 Geo. 3. c. 31, the annual sum of 1,000,000*l*. was placed in the hands of commissioners, who are, the speaker of the house of commons, the chancellor of the exchequer, the master of the rolls, the accomptant-general of the court of chancery, and the governor and deputy-governor of the bank, for the time being respectively. This million was to be issued in four equal quarterly payments, and to be applied either in paying off such redeemable annuities as were at or above par, or in the purchase of annuities below par, at the market-price. The dividends on the sums redeemed or purchased, with the annuities for lives or terms that should fall in or expire, and the sums which might be saved by any reduction of interest, were to be added to the fund, which was thus to continue increasing till it amounted to four millions annually; this it was computed would be in about 26 years, when upwards of 56 millions of stock would have been redeemed, from which time the dividends on such capital as should afterwards be paid off or purchased by the commissioners, with such annuities as might fall in, were to be at the disposal of parliament.

On the 17th of February, 1792, Mr. Pitt proposed that the sum of 400,000*l.* should be issued in addition to the million, for the purpose of accelerating the operation of this fund; and stated, that in consequence of this and future intended additions, it might be expected that 25 millions of 3 per cents. would be paid off by the year 1800; and that in the year 1808, the fund would amount to four millions per annum, being the sum to which it was then restricted. But the most important improvement was a provision, that whenever, in future, any sums should be raised by loans on perpetual redeemable annuities, a sum equal to one per cent. on the stock created by such loans, should be issued out of the produce of the consolidated fund, quarterly, to be placed to the account of the commissioners, who were to keep a separate account of the stock redeemed by this new fund, which was not to affect the accumulation of the original fund. By these means the immediate progress of the fund was quickened, and future loans were put into a regular course of redemption.

The injudicious restriction of the fund to four millions per annum, was done away by an act passed in 1802, which directed that the produce of the two funds should continue to accumulate, without any limitation as to its amount, and be from time to time applied, according to the former provisions, in the redemption or purchase of stock, until the whole of the perpetual redeemable annuities, existing at the time of passing the act, shall have been completely redeemed or paid off. At the same time, the usual annual grant of 200,000*l.* in aid of the fund, was made a permanent charge, to be issued in quarterly payments from the consolidated fund, in the same manner as the original million per annum. In consequence of these improvements, the increase of the fund has been much greater than it was originally estimated; and its total amount, with the sources from which it arose, was on the 1st of February, 1806, as follows:

Annual charge, by act of 26 Geo. III.	£.1,000,000	0	0
Ditto, 42 Geo. III. -	200,000	0	0
Annuities for 99 and 96 years, expired 1792	54,880	14	6
Short annuities, expired 1787 - - -	25,000	0	0
Life annuities, unclaimed and expired - -	50,308	5	7
Dividend on 98,386,402*l.* at 3 per cent. -	2,951,592	1	2
Ditto on 2,617,400*l.* at 4 per cent. - -	104,696	0	0
Ditto on 142,000*l.* at 5 per cent. - -	7,100	0	0
One per cent. on capitals created since 1723	£.3,202,672	1	10
Total	£.7,596,249	3	1

This sum is exclusive of the fund for the reduction of the public debt of Ireland, funded in Great Britain, which at the above period amounted to 479,537*l.* 8*s.* and of the fund for reduction of the imperial debt, which amounted to 55,960*l.* 9*s.* 4*d.*

The commissioners are directed by the act to make their purchases "in equal portions, as nearly as may be, on every day (Saturdays and Mondays excepted) on which the same shall be transferable." So that they purchase on four days in every week in which there are no holidays. They are empowered to subscribe towards any public loan, to be raised by act of parliament, upon perpetual annuities, subject to redemption at par: and an account of the sums issued to them, and of the stock purchased to the 1st of February in every year, is to be annually laid before parliament on or before the 15th of February. The purchases, at first, were all made in the 3 per cents. probably with the view of redeeming the five per cents. if the state of the public funds should render such a measure practicable, or of inducing the proprietors to agree to a reduction of the interest at the time when they should become redeemable.

The progress of the fund from the commencement of its operation on 1st August 1786, to the 1st February 1806, will appear from the following statement of the total amount of the stock redeemed by the commissioners up to the latter period.

Consolidated 3 per cent. annuities - -	£.39,922,421
Reduced 3 per cent. annuities - -	51,493,981
Old South Sea annuities	3,492,000
New South Sea annuities	2,783,000
Three per cents. 1751 -	695,000
Consolidated 4 per cent. annuities - -	2,617,400
Navy 5 per cent. annuities	142,000
Total	£.101,145,802

The total sum which had been paid for this amount of stock, was 62,842,782*l.* 7*s.* 10*d.* the consolidated 3 per cents. having been bought up on an average at 61*l.* per cent. and the reduced at somewhat less.

The progress already made by the fund, and the important effect it has had in supporting the value of the government securities at a time when it has been necessary to borrow unprecedented sums in almost every year, sufficiently demonstrate the great utility of this measure. As its increase will be continually augmenting, it will, if steadily persevered in, and faithfully applied, become ultimately capable of discharging a debt of any amount which it is possible to suppose the country will ever be encumbered with.

It has been shewn that the fund, including the provision for the reduction of the debt in Ireland funded in Great Britain, and for the imperial loans, amounts at present to upwards of eight millions per annum; and as the stock has been bought up at little more than 60 per cent. the money has been improved at nearly 5 per cent. interest. It is neither desirable, nor to be expected, that it will always be possible to invest the produce of the fund at this rate of interest; but it will be shewn that if the fund is never diverted from its purpose, its effects will in time be almost omnipotent, particularly when it is considered that the following sums are money, and consequently much less than the nominal capital of stock that would be bought up at any of the current prices at which these securities have been for many years past:

Amount to which the present sinking fund of eight millions per annum will accumulate, if improved at 4 or 5 per cent. compound interest.

Years.	4 per cent. Millions.	5 per cent. Millions.
In 1810	33	34
1820	146	156
1830	312	356
1840	558	680
1850	923	1209
1860	1463	2070
1870	2261	3472
1880	3443	5757
1890	5193	9478
1900	7782	15540

SINNET, on board a ship, a line or string made of rope-yarn, consisting generally of two, six, or nine strings, which are divided into three parts, and are platted over one another, and then beaten smooth and flat with a wooden mallet. Its use is to save the ropes, or to keep them from galling.

SINOVIA. Within the capsular ligaments of the different joints of the body, there is contained a peculiar liquid, intended to lubricate the parts to facilitate their motion. The only analysis of sinovia is of that taken from oxen.

The sinovia of the ox, when it has just flowed from the joint, is a viscid semitransparent fluid, of a greenish-white colour, and a smell not unlike frog-spawn. It very soon acquires the consistence of a jelly; and this happens equally whether it is kept in a cold or a hot temperature, whether it is exposed to the air or excluded from it. This consistence does not continue long; the sinovia soon recovers again its fluidity, and at the same time deposits a thready-like matter.

Sinovia mixes readily with water, and imparts to that liquid a great deal of viscidity. The mixture froths when agitated; becomes milky when boiled, and deposits some pellicles on the sides of the dish; but its viscidity is not diminished.

When alcohol is poured into sinovia, a white substance precipitates, which has all the properties of albumen. One hundred parts of sinovia contain 4.52 of albumen. The liquid still continues as viscid as ever; but if acetic acid is poured into it, the viscidity disappears altogether, the liquid becomes transparent, and deposits a quantity of matter in white threads, which possesses the following properties: 1. It has the colour, smell, taste, and elasticity, of vegetable gluten. 2. It is soluble in concentrated acids and pure alkalies. 3. It is soluble in cold water; the solution froths. Acids and alcohol precipitate the fibrous matter in flakes. One hundred parts of sinovia contain 11.86 of this matter.

When the liquid, after these substances have been separated from it, is concentrated by evaporation, it deposits crystals of acetat of soda. Sinovia, therefore, contains soda. Margueron found that 100 parts of sinovia contained about 0.71 of soda.

When strong sulphuric, muriatic, nitric, acetic, or sulphurous acid, is poured into sinovia, a number of white flakes precipitate at first, but they are soon re-dissolved, and the viscidity of the liquid continues. When these acids are diluted with five times their weight of water, they diminish the transparency of sinovia, but not its viscidity; but when they are so much diluted that their acid taste is just perceptible, they precipitate the peculiar thready matter, and the viscidity of the sinovia disappears.

When sinovia is exposed to a dry atmosphere, it gradually evaporates, and a scaly residuum remains, in which cubic crystals and a white saline efflorescence are apparent. The cubic crystals are muriat of soda. One hundred parts of sinovia contain about 1.75 of this salt. The saline efflorescence is carbonat of soda.

Sinovia soon putrefies in a moist atmosphere, and during the putrefaction ammonia is exhaled. When it is distilled in a retort, there comes over, first water, which soon putrefies; then water containing ammonia; then empyreumatic oil and carbonat of ammonia. From the residuum muriat and carbonat of soda may be extracted by lixiviation. Sinovia is composed of

11.86	fibrous matter
4.52	albumen
1.75	muriat of soda
.71	soda
.70	phosphat of lime
80.13	water
100.00	

SINUATED LEAF. See BOTANY.

SINUS. See ANATOMY.

SINUS. See SURGERY.

SIPHON, or SYPHON. See HYDROSTATICS.

SIPHONATHUS, a genus of the tetrandria monogynia class and order. The corolla is one-petalled, very long, funnel-form, inferior; berries four, one-seeded. There are two species, herbs of South America.

SIPHONIA, a genus of the class and order monœcia monadelphia. The calyx is one-leaved; no corolla; male anthers five; fem. style none; stigmas three; caps. tricoccous; seed one. There is one species, a tree of Guaiana.

SIPUNCULUS, or *tube-worm*, a genus of insects of the order vermes intestina: the generic character is, body round, elongated; mouth cylindrical at the end, and narrower than the body; aperture at the side of the body, and verruciform. There are two species: the S. nudus, inhabits the European seas, under stones, and is eight inches long. The S. saccatus, body covered with a loose skin, and rounded at the lower end: inhabits the American and Indian seas.

SIREN, a genus of amphibia, of the order meantes, of which there are the following species:

1. Siren lacertina, or eel-shaped siren: This species stands eminently distinguished in the list of animals by the ambiguity of its characters, which are such as to have induced the great Linnæus to institute for it a new order of amphibia, under the title of meantes; an order, however, which does not stand among the rest of the amphibia in the Systema Naturæ, but is mentioned in a note at the end of the second part of the first volume of that work.

The genus with which the siren has the greatest possible affinity, is the lacerta or lizard. It even very much resembles the larva, or first state, of a lacerta; and it is still doubtful whether it may not really be such: yet it has never been observed in any other state, having two feet only, without any appearance of a hind pair; the feet are also furnished with claws, whereas the larvæ of all the lacertæ are observed to be without claws; or, in the Linnæan phrase, digitis muticis; the mouth has several rows of smallish teeth; the body is eel-shaped, but slightly flattened beneath, marked on the sides by several wrinkles, and slightly compressed towards the extremity of the tail, which is edged with a kind of soft skin or adipose fin; on each side the neck are three ramified branchial processes, resembling, on a larger scale, those belonging to the larva of water-newts, and at the base are the openings into the gills: the eyes are very small and blue. The general colour of the animal is a deep or blackish brown, scattered over, especially on the sides, with numerous minute whitish specks. Its size nearly equals that of an eel, being frequently found of the length of more than two feet. It is a native of North America, and more particularly of South Carolina, where it is not very uncommon in muddy and swampy places, living generally under water, but sometimes appearing on land. It has a kind of squeaking or singing voice, for which reason Linnæus distinguishes it by the title of siren. See Plate Nat. Hist. fig. 367.

It remains to be added, that the siren, if thrown on the ground with any degree of violence, has been observed to break in two or three places; in this particular resembling the anguis fragilis, or slow-worm. It is also proper to observe, that no lizard of which it may be supposed the larva, has ever yet been discovered in those parts of Carolina where it is most frequent. The species to which it seems most allied is the lacerta teguixin of Linnæus, which is a native of South America.

2. Siren anguina, anguine siren. This singular animal is found in as singular a situation, being an inhabitant of the celebrated and romantic lake called Lake Zirknitz, about six German miles from Labac, in the duchy of Carolina, in Austria. From this lake, which is somewhat more than a German mile in length, and half as much in breadth, the water regularly retires during the summer, by numerous subterraneous outlets or holes at the bottom; leaving the ground dry, and fit for pasture, the cultivation of millet, &c. &c. as well as for various kinds of hunting and other amusements; but in the month of October it again returns, with great force, springing out of the passages before mentioned from a vast depth till the lake is completely filled. It is situated in a hollow or valley, surrounded by rocky and woody mountains, in which are vast caverns, and is principally supplied by eight rivulets running into it from the adjoining mountainous region.

The species of siren at present to be described is extremely rare; and is found in the spring, and towards the decline of summer, in some particular parts of the above-mentioned lake; and commonly measures, when full-grown, from about ten to twelve or thirteen inches in length; the largest specimens being near three quarters of an inch in diameter. It is entirely of a pale rose or flesh-colour, or even nearly white, except the three pair of ramified branchial fins on each side the neck, which are of a bright red or carmine-colour. Its general shape is that of an eel; the body being cylindric, till towards the end of the tail, where it becomes flat, and is attenuated both above and below into a kind of fatty fin, scarcely distinguishable from the rest of the tail; the skin is every where smooth and even; the head of a somewhat depressed form; with a lengthened, obtuse, and widish snout, and has no external eyes; the mouth is moderately wide, and furnished with a row of very minute teeth; the legs are about $\frac{3}{4}$ of an inch in length, the fore legs being situated almost immediately behind the branchial fins, and the feet furnished with three toes, without any appearance of claws; the hind legs are situated at a great distance backwards, towards the commencement of the tail, and are of the same appearance with the fore legs; but the feet have only two toes, which, like those of the fore feet, are destitute of claws. The motions of the animal, when taken out of the water, are, in general, extremely slow and languid; as is also the case when kept in a vessel of water; but when in its native lake, it is sometimes observed to swim pretty briskly, waving its body in a serpentine direction in the manner of a leech.

3. Siren pisciformis, fish-formed siren. This animal in its natural size is supposed to be a native of Mexico, and though perhaps no other than the larva or tadpole of some large American lizard, scarcely seems a less singular and curious animal than the siren lacertina. In its general appearance it bears some resemblance to the larva of the rana paradoxa, but is furnished with gills, opening externally in the manner of a fish; the openings are very large, and the operculum or external flap is continued from the sides of the head across the throat beneath, so as completely to insulate the head from the breast; the gills themselves consist of four semicircular bony or cartilaginous arches, which are denticulated or serrated on their internal or concave part, like those of fishes; on the opercula or external flaps are situated three very large and elegant branchial fins or ramified parts, divided or subdivided into a vast number of slender or capillary processes. In these particulars it resembles the siren lacertina, except that in that animal the external opening to the gills is very small; the mouth is furnished in front with a row of extremely minute teeth; the tongue is large, smooth, and rounded at the tip: the rictus, or gape, when the mouth is closed, appears considerably wider than it really is, owing to a lateral sulcus proceeding from each corner to some distance; the feet are entirely destitute of webs, and the toes are furnished with weak

ish claws; the fore feet have four, and the hind feet five toes. Exclusive of the general colour of the animal, the whole skin, when minutely examined, appears to be scattered over with very minute white specks, resembling those on the surface of the siren lacertina. The sides of the body are marked by several strong rugæ or furrows, and an impressed lateral line or sulcus is continued from the gills to the tail.

SIREX, a genus of insects of the hymenoptera order. The generic character is, mouth with two strong jaws; feelers two, truncated; antennæ filiform, with more than twenty-four joints; piercer exserted, stiff, serrated; abdomen sessile, pointed; wings lanceolate, flat in all.

The larvæ of these insects are of a lengthened, cylindric appearance, living in the decayed parts of trees, on the substance of which they feed; the chrysalis, as in the tenthredo, exhibits the limbs of the perfect insect in a contracted state.

The largest species is the sirex gigas of Linnæus, which surpasses a hornet in size, and is principally observed in the neighbourhood of pines and other coniferous trees; it is of a black colour, with the eyes, the base, and lower half of the abdomen, bright orange-yellow; the thorax villose, and the wings of transparent yellowish brown; the sting or a terminal tube is very conspicuous. The larva, which measures about an inch and a quarter in length, is of a yellowish white colour, and inhabits decayed firs and pines; at first view it bears some resemblance to the larvæ of the beetle tribe, but is thinner in proportion, and furnished at the tip of the abdomen with a short black spine or process. It changes to a chrysalis in July, first enveloping itself in a slight silken web of a whitish colour. If the change to chrysalis takes place in summer, the fly proceeds from it in the space of about three weeks; but if at the close of autumn, the animal continues in chrysalis the whole winter, emerging in the following spring. The male insect is considerably smaller than the female, and may be farther distinguished by the want of the caudal tube or process so conspicuous in the female insect; the tip of the abdomen is also of a black colour. The eggs, which are deposited by the female in the decayed parts of the trees above mentioned, are very small, and of a lengthened oval shape with pointed extremities.

Sirex columba is an American species, and is distinguished by its black body, marked by testaceous bands.

Sirex pygmæus is one of the smallest of the European species, being, according to Linnæus, about the size of a gnat, with a black abdomen, marked by three yellow bands, the middle of which is interrupted. It is found in Sweden. There are seven species.

SIRIUS, the DOG-STAR. See ASTRONOMY.

SIRIUM, a genus of plants belonging to the class of tetrandria and order of monogynia. The calyx is quadrifid; there is no corolla; the nectarium is quadriphyllous, and crowning the throat of the calyx; the germen is below the corolla; the stigma is trifid, and the berry trilocular. There is only one species, the myrtifolium.

SIROCCO. The sirocco (so called by the Italians because it is supposed to blow from Syria, and in the south of France the Levant wind) resembles in some of its effects the harmattan, but differs from it in being extremely insalubrious. It sometimes blows for several days together, to the great annoyance of the whole vegetable and animal creation; its medium heat is calculated at one hundred and twelve degrees; it is fatal to vegetation and destructive to mankind, and especially to strangers; it depresses the spirits in an unusual degree; it suspends the powers of digestion, so that those who venture to eat a heavy supper while this wind prevails, are commonly found dead in their beds the next morning, of what is called an indigestion. The sick, at that afflicting period, commonly sink under the pressure of their diseases; and it is customary in the morning, after this wind has continued a whole night, to inquire who is dead.

We shall now insert an account of this baleful wind, from an interesting work on the present state of Sicily.

"The evil most to be dreaded in traversing these regions is, perhaps, the sirocco, or south wind, which it is imagined blows from the burning deserts of Africa, and is sometimes productive of dangerous consequences to those who are exposed to its fury. During the continuance of this wind all nature appears to languish, vegetation withers and dies, the beasts of the field droop, the animal spirits seem too much exhausted to admit of the least bodily exertion, and the spring and elasticity of the air appear to be lost. The heat exceeds that of the most fervid weather in Spain or Malta, and is felt with peculiar violence in the city and neighbourhood of Palermo.

"The sensation occasioned by the sirocco wind is very striking and wonderful. In a moment the air becomes heated to an excessive degree, and the whole atmosphere feels as if it was inflamed; the pores of the body seem at once opened, and all the fibres relaxed. During its continuance the inhabitants of Palermo shut their doors and windows to exclude the air; and where there are no window-shutters, wet blankets are hung on the inside of the window, and the servants are kept continually employed in sprinkling the apartments with water. No creature, whose necessities do not compel him to the exertion, is to be seen while this tremendous wind continues to blow, and the streets and avenues of the city appear to be nearly deserted.

"The sirocco generally continues so short a time in Sicily, that it seldom produces those complaints which are the consequence of its scorching heats in several parts of Italy, though its violence in those countries is much inferior to what is felt in this island. Here it seldom endures longer than thirty-six or forty hours; a time not sufficient to heat the ground, or the walls of the houses, in a very intense continued degree. It is commonly succeeded by the tramontane, or north wind, which in a short time restores the exhausted powers of animal and vegetable life, and nature soon assumes her former appearance. The cause of the sirocco wind has been frequently attempted to be explained, but the different hypotheses are perhaps more to be admired for their ingenuity and fancy than for being very satisfactorily explained. The superior intenseness of this scorching wind at Palermo, may perhaps be accounted for from the situation of that city, which is almost surrounded by lofty mountains, the ravines and valleys of which are parched and almost burnt up in summer. The numberless springs of warm water must also greatly increase the heat of the air; and the practice of burning brush-wood and heath on the neighbouring mountains, during the warm season, must undoubtedly tend to increase the heat of the wind in passing over the country of Sicily, though it had previously been disarmed of part of its violence by travelling over the sea which divides Sicily from Africa."

Whether the fatal effects of the sirocco depend entirely upon the degree of fever which is produced by the extreme heat which accompanies it, or whether it is really charged with any quantity of mephitic gas, we have never been sufficiently informed; but wish that any intelligent traveller would examine the state of the air by the eudiometer, and by other tests, during the prevalence of this wind. Should it be found loaded with carbonic gas, its ill effects might be easily obviated by suspending in the different apartments, cloths dipped in lime-water; but from the present state of the evidence we are disposed to think that all its evil consequences depend upon the sudden increase of the temperature only.

An extraordinary blasting wind is felt occasionally at Falkland's islands. Happily its duration is short; it seldom continues above twenty-four hours. It cuts the herbage down as if fires had been made under them; the leaves are parched up, and crumble into dust. Fowls are seized with cramps so as never to recover. Men are oppressed with a stopped perspiration, heaviness at the breast, and sore throat; but usually recover with care.

This account is extracted from the travels of Mr. Ives over land to the East Indies. Its fatal effects, if the statement is perfectly correct, evidently proceed from a certain portion of extremely putrid vapours with which it is charged, and we suspect it only happens when a strong wind chances to blow over some very putrid and stagnant lake which is not far distant; travellers, however, are on such occasions commonly in a state of too much alarm to note circumstances with accuracy, and too much of their accounts is collected upon hearsay evidence. This wind, after all, may only consist of a mephitic vapour which destroys life when inhaled; and the putridity which is said so rapidly to take place, may depend more upon the climate than the nature of the wind.

SISON, *bastard stone-parsley*: a genus of plants belonging to the class of pentandria, and to the order of digynia; and in the natural system arranged under the 45th order, umbellatæ. The fruit is egg-shaped and streaked; the involucra are subtetraphyllous. There are six species; the amomum, inundatum, segetum, salsum, canadense, and ammi. The three first are natives of Great Britain. 1. The amomum, common bastard parsley, or field stone-wort, is a biennial plant about three feet high, growing wild in many places of Britain. Its seeds are small, striated, of an oval figure and brown colour. Their taste is warm and aromatic. Their whole flavour is extracted by spirit of wine, which elevates very little of it in distillation; and hence the spirituous extract has the flavour in great perfection, while the watery extract has very little. A tincture drawn with pure spirit is of a green colour. The seeds have been esteemed aperient, diuretic, and carminative; but are little regarded in the present practice. 2. The inundatum, least water-parsnip; it grows in ditches and ponds. 3. Segetum, corn parsley or honey-wort: it grows in corn-fields and hedges.

SISYMBRIUM, *water-cresses*, a genus of plants belonging to the class of tetradynamia, and to the order of siliquosa; and in the natural system ranged under the 39th order, siliquosæ. The siliqua, or pod, opens with valves somewhat straight. The calyx and corolla are expanded. There are fifty-three species, of which eight are natives of Britain: the nasturtium, or common water-cress; sylvestre, water-rocket; amphibium, water-radish; terrestre, annual water-radish; monense; sophia, flixweed; irio, broad-leaved hedge-mustard.

SISYRINCHIUM, a genus of plants belonging to the class of monadelphia, and order of triandria; and in the natural system ranked under the 6th order, ensatæ. The spatha is diphyllous; there are six plane petals. The capsule is trilocular and inferior. There are ten species, natives of North America and the Cape.

SITTA, *nut-hatch*, a genus belonging to the class of aves, and order of picæ. It is thus characterized by Dr. Latham: The bill is for the most part straight; on the lower mandible there is a small angle; nostrils small, covered with bristles reflected over them; tongue short, horny at the end, and jagged; toes placed three forward and one backward, the middle toe joined closely at the base to both the outmost; back toe as large as the middle one. There are eleven species; the europæa, canadensis, carolinensis, jamaicensis, pusilla, major, nævia, surinamensis, cafra, longirosta, and chloris. The europæa, or nut-hatch, is in length near five inches three-quarters, in breadth nine inches; the bill is strong and straight, about three-quarters of an inch long; the crown of the head, back, and coverts of the wings, of a fine bluish grey; a black stroke passes over the eye from the mouth; the cheeks and chin are white; the breast and belly of a dull orange-colour. The female is like the male, but less in size, and weighs commonly five or at most six drams. The eggs are six or seven in number, of a dirty white, dotted with rufous; these are deposited in some hole of a tree, frequently one which has been deserted by a woodpecker, on the rotten wood mixed with a little moss, &c. If the entrance is too large, the bird nicely stops up part of it with clay, leaving only a small hole for itself to pass in and out by. While the hen is sitting, if any one puts a bit of stick into the hole, she hisses like a snake, and is so attached to her eggs, that she will sooner suffer any one to pluck off her feathers than fly away. During the time of incubation, the male supplies her with sustenance.

The bird runs up and down the bodies of trees, like the woodpecker tribe; and feeds not only on insects, but nuts, of which it lays up a considerable provision in the hollows of trees. Dr. Plott tells us, that this bird, by putting its bill into a crack in the bough of a tree, can make such a violent sound as if it was rending asunder, so that the noise may be heard at least twelvescore yards.

SIUM, *water parsnip*, a genus of plants belonging to the class of pentandria, and order of digynia, and in the natural system ranging under the 45th order, umbellatæ. The fruit is a little ovated, and streaked. The involucrum is polyphyllous, and the petals are heart-shaped. There are nineteen species; three are natives of Britain: 1. The latifolium, or great water-parsnip, which grows spontaneously in many places both of England and Scotland, on the sides of lakes, ponds, and rivulets. Cattle are said to have run mad by feeding upon this plant. 2. The angustifolium, or narrow-leaved water-parsnip, grows in ditches and rivulets, but is not common. 3. The nodiflorum, reclining water-parsnip, grows on the sides of rivulets.

The sium sisarium, or skirret, is a native of China, but has been for a long time cultivated in Europe, and particularly in Germany. The root is a bunch of fleshy fibres, each of which is about as thick as a finger, but very uneven, covered with a whitish rough bark, and has a hard core or pith running through the centre. Skirrets come nearest to parsnips of any of the esculent roots, both for flavour and nutritive qualities. They are rather sweeter than the parsnip, and therefore to some few palates are not altogether so agreeable. Mr. Margraaf extracted from half a pound of skirret-root an ounce and a half of pure sugar.

SIXTH, in music, an interval formed of six sounds, or five diatonic degrees. There are four kinds of sixths, two consonant and two dissonant. The consonant sixths, are first, the minor sixth, composed of three tones and two semitones major. Secondly, the major sixth, composed of four tones and a major semitone. The dissonant sixths are, first the diminished sixth, composed of two tones and three major semitones. Secondly, the superfluous sixth, composed of four tones, a major semitone, and a minor semitone.

SIZE, the name of an instrument used to find the bigness of fine round pearls. It consists of thin pieces or leaves, about two inches long and half an inch broad, fastened together at one end by a rivet. In each of these are round holes drilled of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains; those of the second, for pearls from eight grains or two carats, to five carats, &c.; and those of the third, for pearls from six carats and a half to eight carats and a half.

SIZE. See GELATINA.

SKAITE. See RAIA.

SKELETON. See ANATOMY.

SKIMMIA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is quadripartite; the corolla consists of four concave petals; and the berry contains four seeds. There is only one species, viz. the japonica.

SKIN. See CUTIS.

SKINNER, one who works in skins. Skinners, or fellmongers, shall not retain any journeyman, &c. to work in their trade, except they themselves have served seven years as apprentices thereto, on pain of forfeiting double the value of the wares wrought by such persons.

SKULL, cranium et calvaria. See ANATOMY.

SLAB, an outside sappy plank or board sawed off from the sides of a timber-tree; the word is also used for a flat piece of marble.

SLATE. This stone constitutes a part of many mountains. Its structure is slaty. Its texture foliated. Fracture splintery. Fragments often tabular. Lustre most commonly silky. Specific gravity from 2.67 to 2.88. Does not adhere to the tongue. Gives a clear sound when struck. Streak white or grey. Colour most commonly grey, with a shade of blue, green, or black; sometimes purplish, yellowish, mountain-green, brown, bluish-black; sometimes striped or spotted with a darker colour than the ground.

It is composed, according to Kirwan, of silica, alumina, magnesia, lime, oxide of iron. In some varieties the lime is wanting. Several varieties contain a considerable quantity of carbonaceous matter.

SLAVERY. The law of England abhors, and will not endure, the existence of slavery within this nation. A slave or negro, the moment he lands in England, falls under the protection of the laws, and becomes a free man.

SLEDGE, a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, &c.

This is also the name of a large smith's hammer, to be used with both hands. Of this there are two sorts; the up-hand sledge, which is used by under-workmen, when the work is not of the larger sort; it is used with both the hands before, and they seldom raise it higher than their head: but the other, which is called the about-sledge, and which is used for battering or drawing out the largest work, is held by the handle with both hands, and swung round over their heads at their arm's end, to strike as hard a blow as they can.

SLEEP. See PHYSIOLOGY.

SLEEPERS, in a ship, timbers lying before and aft, in the bottom of the ship, as the rung-heads do; the lowermost of them is bolted to the rung-heads, and the uppermost to the futtocks and rungs.

SLINGING, is used variously at sea, but chiefly for the hoisting up casks, or other heavy things, with slings; *i.e.* contrivances of ropes spliced into themselves, at either end, with one eye big enough to receive the cask, or other thing, to be slung.

SLOANEA, a genus of plants belonging to the class of polyandria, and order of monogynia; and in the natural system ranking under the 50th order, amentaceæ. There is no corolla; the calyx is monophyllous; the stigma is perforated; the berry is corticose, echinated. There are three species, large trees of South America and the West Indies.

SLOATH, or SLOTH. See BRADYPUS.

SLOE, prunus sylvestris, the English name for the wild plum. See PRUNUS.

SLOOP, a sort of small ship or vessel, usually with one mast, otherwise called shallop. In our navy, sloops are tenders on the men of war, and are usually of about sixty tons, and carry about thirty men.

SLOW-WORM. See ANGUIS.

SLUICE, in hydraulics, a frame of timber, stone, earth, &c. serving to retain and raise the water of the sea, a river, &c. and on occasion to let it pass; such is the sluice of a mill, which stops and collects the water of a rivulet, &c. in order to discharge it at length, in greater plenty, upon the mill-wheel; such also are those used in drains, to discharge water off lands; and such are the sluices of Flanders, &c. which serve to prevent the waters of the sea overflowing the lower lands, except when there is occasion to drown them. See CANAL.

Construction of sluices. The construction of sluices ought to be conducted by an able engineer, who is well acquainted with the action of fluids in general; and particularly with the situation of the place, the nature of the soil, &c. where the sluice is to be erected; if on the sea-shore, he ought to be perfectly well acquainted with the effects of the sea on that coast, and the seasons when it is calm or stormy, that he may be able to prevent the fatal accidents thence arising; and if in a river, it is necessary to know whether it usually overflows its banks, and at what seasons of the year its waters are highest and lowest. The machines for driving the piles should be placed about forty yards from the side of the sluice, above and below it. As to the depth of sluices, it must be regulated by the uses for which they are designed; thus, if a sluice is to be erected at the entrance of a bason for shipping, its depth must correspond with the draught of water of the largest ship that may, at any time, have occasion to enter by it. The rule usually observed, is to make the surface of the bottom of the canal on a level with the low-water mark; but if the bottom of the harbour or canal is such as to be capable of becoming deeper by the action of the water, Belidor very justly observes, that the bottom of the sluice-work should be made deeper than either.

When a sluice is to be placed at the bottom of a harbour, in order to wash away the filth that may gather in it, by means of the waters of a river or canal; in this case the bottom of the sluice-work should be two feet or eighteen inches higher than the bottom of the harbour, that the water may run with the greater violence.

An engineer ought always to have in his view, that the faults committed in the construction of sluices are almost always irreparable. We shall therefore lay down some rules, from Belidor, for avoiding any oversights of this kind: 1. In order to adjust the level of the sluice-work with the utmost exactness, the engineer ought to determine how much deeper it must be than a fixed point; and this he should mark down in his draught, in the most precise terms possible. 2. When the proper depth is settled, the foundation is next to be examined; and here the engineer cannot be too cautious, lest the apparent goodness of the soil deceive him; if the foundation is judged bad, or insufficient to bear the superstructure, it must be secured by driving piles, or a grate-work of carpentry. 3. There should be engines enough provided for draining the water; and these should be entirely under the direction of the engineer, who is to take care that they are so placed as not to be an obstacle to the work; and also cause proper trenches to be cut, to convey the water clear off from the foundation. 4. When the sluice is to be built in a place where the workmen will be unavoidably incommoded by the waters of the sea, &c. all the stones for the mason-work, as well as the timbers for that of carpentry, should be prepared beforehand; so that when a proper season offers for beginning the work, there remains nothing to be done, but to fix every thing in its place.

Sluices are made different ways, according to the uses they are intended for; when they serve for navigation, they are shut with two gates, presenting an angle towards the stream; but when made near the sea, there are two pair of gates, one to keep the water out, and the other to keep it in, as occasion requires; the pair of gates next the sea present an angle that way, and the other pair the contrary way; the space inclosed by these gates is called a chamber.

When sluices are designed to detain the water in some parts of the ditch of a fortress, they are made with shutters to slide up and down in grooves; and when they are made to cause an inundation, they are then shut by means of square timbers let down into cullises, so as to lie close and firm.

SMALT, a kind of glass of a dark-blue colour, which, when levigated, appears of a most beautiful colour; and if it could be made sufficiently fine, would be an excellent succedaneum for ultramarine, as not only resisting all kinds of weather, but even the most violent fires. It is prepared by melting one part of oxide of cobalt with two of flint-powder, and one of potass. At the bottoms of the crucibles in which the smalt is manufactured, we generally find a regulus of a whitish colour inclining to red, and extremely brittle. This is melted afresh, and when cold, separates into two parts; that at the bottom is the cobaltic regulus, which is employed to make more of the smalt; the other is bismuth.

SMARAGDITE, in mineralogy. This stone was called smaragdite by M. Saussure, from some resemblance which it has to the emerald. Never crystallized. Its texture is foliated. Easily divided into plates. The laminæ are inflexible. Fracture even. Specific gravity 3. Colour in some cases fine green; in others it has the grey colour and metallic lustre of mica; it assumes all the shades of colour between these two extremes.

According to the analysis of Vauquelin, it is composed of

50.0	silica
13.0	lime
11.0	alumina
7.5	oxide of chromium
6.0	magnesia
5.5	oxide of iron
1.5	oxide of copper
94.5	

SMELT. See SALMO.

SMELTING, in metallurgy, the fusion or melting of the ores of metals, in order to separate the metalline part from the earthy, stony, and other parts.

SMELTING, or the art of fusing the ores after roasting, is the principal and most important of metallurgic operations, all the other being preliminary or preparative to this. The whole attention of the miner is directed towards this process; to this all his efforts are applied, because it affords the truly useful product to which his hopes are directed. Though it consists in general in fusing the roasted ore to extract the metal, and in this point of view it seems to present a simple and uniform operation, there is, nevertheless, no operation which differs so much in its circumstances, according to the nature of the metal and the ore required to be treated, and according to the furnaces made use of, the nature and quantity of the combustible employed, the energy, duration, and administration of the fire, the addition of an appropriate flux, the heat being applied in the midst of the coal or in crucibles, the period, the length of time, and the mode of casting the fused metal; every thing, even the form of the metal which flows out, varies, and presents to the observer very remarkable differences.

When the ore is smelted, and the metal obtained, the whole process is not yet finished. This metal is scarcely ever pure. It is either altered by certain substances foreign to its metallic nature; or it contains a portion of another metal, which alters the properties of this which is desired in a pure state; or else it contains a portion of a metal more valuable than all the rest of the mass, which it is necessary therefore to extract; or, lastly, it is an alloy, in large proportions of several metals, which are required to be separated from each other. All the operations subsequent to the smelting, are comprehended under the general name of refining, because the effect is always to obtain a pure metal. See METALLURGY.

SMILAX, *rough bindweed*; a genus of plants belonging to the class of diœcia and order of hexandria; and in the natural system ranging under the 11th order, sarmentaceæ. The male calyx is hexaphyllous, and there is no corolla; the female calyx is also hexaphyllous, without any corolla; there are three styles, a trilocular berry, and two seeds. There are 22 species; of these, the smilax sarsaparilla, which affords the sarsaparilla root, is the most valuable. This is well described in the London Medical Journal by Dr. Wright, who, during a long residence in Jamaica, made botany his peculiar study.

"This species (says he) has stems of the thickness of a man's finger; they are jointed, triangular, and beset with crooked spines. The leaves are alternate, smooth and shining on the upper side: on the other side are three nerves or costæ, with sundry small crooked spines. The flower is yellow, mixed with red. The fruit is a black berry, containing several brown seeds.

"Sarsaparilla delights in low moist grounds and near the banks of rivers. The roots run superficially under the surface of the ground. The gatherers have only to loosen the soil a little, and to draw out the long fibres with a wooden hook. In this manner they proceed till the whole root is got out. It is then cleared of the mud, dried, and made into bundles.

"The sensible qualities of sarsaparilla are mucilaginous and farinaceous, with a slight degree of acrimony. The latter, however, is so slight as not to be perceived by many; and I am apt to believe that its medicinal powers may fairly be ascribed to its demulcent and farinaceous qualities."

The china, or oriental species of China

root, has roundish, prickly stalks and red berries, and is a native of China and Japan. The pseudo-china, or occidental species, has rounder smooth stalks and black berries, grows wild in Jamaica and Virginia, and bears the colds of our own climate. At present the China root is very rarely made use of, having for some time given place to sarsaparilla, which is supposed to be more effectual. Prosper Alpinus informs us, that this root is in great esteem among the Egyptian women for procuring fatness and plumpness.

SMITHERY, or SMITHING, a manual art, by which an irregular lump of iron is wrought into an intended shape.

SMITHIA, a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32nd order, papilionaceæ. The calyx is monophyllous and bilabiated; the corolla winged; the legumen inclosed in the calyx, with three or four joints, and containing as many seeds, which are smooth, compressed, and kidney-shaped. There is only one species, viz. the sensitiva, an annual of the East Indies.

SMOKE. See EVAPORATION, Vol. I. p. 687.

SMOKE-JACK. See JACK.

SMUT. See HUSBANDRY.

SMYRNIUM, ALEXANDERS; a genus of plants belonging to the class of pentandria, and to the order of digynia; and in the natural system ranging under the 45th order, umbellatæ. The fruit is oblong and striated: the petals have a sharp point, and are keel-shaped. There are seven species: 1. The perfoliatum, or perfoliate alexanders, which is a native of Candia and Italy; 2. The Ægyptiacum; 3. The aureum, or golden alexanders, which is a native of North America; 4. The integerrimum; 5. The olusatrum, common alexanders, a native of Britain; the leaves of which are cauline, ternate, petiolated, and serrated. It grows on the sea-coast at Dunglass on the borders of Berwickshire, North Britain. Since the introduction of celery into the garden, the alexanders is almost forgotten. It was formerly cultivated for salading, and the young shoots or stalks blanched were eaten either raw or stewed. The leaves too were boiled in broths and soups. It is a warm comfortable plant to a cold weak stomach, and was in much esteem among the monks, as may be inferred by its still being found in great plenty by old abbey-walls. 6. Laterale. 7. Apiifolium.

SNAIL. See HELIX, and LIMAX.

SNOW. See METEOROLOGY.

SNOWDROP. See GALANTHUS.

SNOWDROP-TREE. See CHIONANTHUS.

SNUFF, a powder chiefly made of tobacco, the use of which is too well known to need any description here. See NICOTIANA.

SNAPDRAGON, in botany. See ANTIRRHINUM.

SOAP. The fixed oils have the property of combining with alkalies, earths, and metallic oxides, and of forming with these bodies a class of compounds which have received the name of soaps. As these soaps differ from each other very materially, according as their base is an alkali, an earth, or an oxide, it will be proper to consider each set separately.

SOAPS, *alkaline*. As there are a great number of fixed oils, all or most of which are capable of combining with alkalies, earths, and oxides, it is natural to suppose that there are as many genera of alkaline soaps as there are oils. That there are differences in the nature of soaps corresponding to the oil which enters into their composition, is certain; but these differences are not of sufficient importance to require a particular description. It will be sufficient, therefore, to divide the alkaline soaps into as many species as there are alkalies, and to consider those soaps which have the same alkaline base, but differ in their oil, as varieties of the same species.

Soap of soda, or hard soap. The word soap (sapo σαπων) first occurs in the works of Pliny and Galen, and is evidently derived from the old German word, sepe. Pliny informs us that soap was first discovered by the Gauls; that it was composed of tallow and ashes; and that the German soap was reckoned the best.

Soap may be prepared by the following process: a quantity of the soda of commerce is pounded, and mixed in a wooden vessel, with about a fifth part of its weight of lime, which has been slacked and passed through a sieve immediately before. Upon this mixture a quantity of water is poured, considerably more than what is sufficient to cover it, and allowed to remain on it for several hours. The lime attracts the carbonic acid from the soda, and the water becomes strongly impregnated with the pure alkali, which in that state is caustic. This water is then drawn off by means of a stop-cock, and called the first ley. Its specific gravity should be about 1.200.

Another quantity of water is then to be poured upon the soda, which, after standing two or three hours, is also to be drawn off by means of the stop-cock, and called the second ley.

Another portion of water is poured on; and after standing a sufficient time, is drawn off like the other two, and called the third ley.

Another portion of water may still be poured on, in order to be certain that the whole of the soda is dissolved; and this weak ley may be put aside, and employed afterwards in forming the first ley in subsequent operations.

A quantity of oil, equal to six times the weight of the soda used, is then to be put into the boiler, together with a portion of the third or weakest ley; and the mixture must be kept boiling and agitated constantly by means of a wooden instrument. The whole of the third ley is to be added at intervals to the mixture; and after it is consumed, the second ley must be added in the same manner. The oil becomes milky, combines with the alkali, and after some hours it begins to acquire consistence. A little of the first ley is then to be added, not forgetting to agitate the mixture constantly. Portions of the first ley are to be added at intervals; the soapy substance acquires gradually greater consistency, and at last it begins to separate from the watery part of the mixture. A quantity of common salt is then to be added, which renders the separation much more complete. The boiling is to be continued still for two hours, and then the fire must be withdrawn, and the liquor must be no longer agitated. After some hours repose, the soap separates completely from the watery part, and swims upon the surface of the liquor. The watery part is then to be drawn off; and as it contains a quantity of carbonat of soda, it ought to be reserved for future use.

The fire is then to be kindled again; and, in order to facilitate the melting of the soap, a little water, or rather weak ley, is to be added to it. As soon as it boils, the remainder of the first ley is to be added to it at intervals. When the soap has been brought to the proper consistence, which is judged of by taking out small portions of it and allowing it to cool, it is to be withdrawn from the fire, and the watery part separated from it as before. It is then to be heated again, and a little water mixed with it, that it may form a proper paste. After this let it be poured into the vessels proper for cooling it; in the bottom of which there ought to be a little chalk in powder, to prevent the soap from adhering. In a few days, the soap will have acquired sufficient consistence to be taken out, and formed into proper cakes.

The use of the common salt in the above process is, to separate the water from the soap; for common salt has a stronger affinity for water than soap has.

Olive-oil has been found to answer best for making soap, and next to it perhaps tallow may be placed; but a great variety of other oils may be employed for that purpose, as appears from the experiments of the French chemists. They found, however, that linseed-oil and whale-oil were not proper for making hard soaps, though they might be employed with advantage in the manufacture of soft soaps. Whale-oil has been long used by the Dutch for this last purpose.

Soap may also be made without the assistance of heat; but in that case a much longer time and a larger proportion of alkali are necessary.

Manufacturers have contrived various methods of sophisticating soap, or of adding ingredients which increase its weight without increasing its value. The most common substance used for that purpose is water; which may be added in considerable quantities, especially to soap made with tallow (the ingredient used in this country), without diminishing its consistency. This fraud may be easily detected, by allowing the soap to lie for some time exposed to the air. The water will evaporate from it, and its quantity will be discovered by the diminution of the weight of the soap. As soap sophisticated in this manner would lose its water by being kept, manufacturers, in order to prevent that, keep their soap in saturated solutions of common salt; which do not dissolve the soap, and at the same time, by preventing all evaporation, preserve, or rather increase, the weight of the soap. Messrs. Darcet, Lelievre, and Pelletier, took two pieces equal in weight of soap sophisticated in this manner, and placed the one in a dry place in the open air, and the other in a saturated solution of common salt. After a month the first had lost 0.56 of its weight, the other had gained about 0.10 parts. Various other methods have been fallen upon to sophisticate soap; but as they are not generally known, it would be doing an injury to the public to describe them here.

Different chemists have analysed soap, in order to ascertain the proportions of its ingredients; but the result of their experiments is various, because they used soap containing various quantities of water. From the experiments of Darcet, Lelievre, and Pelletier, it appears that soap newly made and exposed to sale contains

60.94	oil
8.56	alkali
30.50	water
100.00	

Soap is soluble both in water and in alcohol. Its properties as a detergent are too well known to require any description.

Soap made with tallow and soda has a white colour, and is therefore known by the name of white soap; but it is usual for soap-makers, in order to lower the price of the article, to mix a considerable portion of rosin with the tallow; this mixture forms the common yellow or turpentine soap of this country.

Soap of potass, or soft soap. Potass may be substituted for soda in making soap, and in that case precisely the same process is to be followed. It is remarkable, that when potass is used, the soap does not assume a solid form; its consistence is never greater than that of hog's lard. This is what in this country is called soft soap. Its properties as a detergent do not differ materially from those of hard soap, but it is not nearly so convenient for use. The alkali employed by the antient Gauls and Germans in the formation of soap was potass; hence we see the reason that it is described by the Romans as an unguent. The oil employed for making soft soap in this country is whale-oil. A little tallow is also added, which, by peculiar management, is dispersed through the soap in fine white spots.

Some persons have affirmed that they knew a method of making hard soap with potass. Their method is this: After forming the soap in the manner above described, they add to it a large quantity of common salt, boil it for some time, and the soap becomes solid when cooled in the usual way. That this method may be practised with success, has been ascertained by Messrs. Darcet, Lelievre, and Pelletier; but then the hard soap thus formed does not contain potass but soda; for when the common salt (muriat of soda) is added, the potass of the soap decomposes it, and combines with its muriatic acid, while at the same time the soda of the salt combines with the oil, and forms hard soap; and the muriat of potass formed by this double decomposition is dissolved in water, and drawn off along with it.

Chaptal has lately proposed to substitute wool in place of oil in the making of soap. The ley is formed in the usual manner, and made boiling hot, and shreds of woollen cloth of any kind are gradually thrown into it; they are soon dissolved. New portions are to be added sparingly, and the mixture is to be constantly agitated. When no more cloth can be dissolved, the soap is made. This soap is said to have been tried with success. It might doubtless be substituted for soap with advantage in several manufactures, provided it can be obtained at a cheaper rate than the soaps at present employed.

Some time ago a proposal was made to substitute the muscles of fish instead of tallow or oil in the manufacture of soap; but the experiments of Mr. Jamieson have demonstrated that they do not answer the purpose.

Soap of ammonia. This soap was first particularly attended to by Mr. Berthollet. It may be formed by pouring carbonat of ammonia on soap of lime. A double decomposition takes place, and the soap of ammonia swims upon the surface of the liquor in the form of an oil; or it may be formed with still greater ease by pouring a solution of muriat of ammonia into common soap dissolved in water.

It has a more pungent taste than common soap. Water dissolves a very small quantity of it; but it is easily dissolved in alcohol. When exposed to the air, it is gradually decomposed. The substance called volatile linament, which is employed as an external application in rheumatisms, colds, &c. may be considered as scarcely any thing else than this soap.

All the alkaline soaps agree in the properties of solubility in water and alcohol, and in being powerful detergents.

Soaps, *earthy.* The earthy soaps differ essentially from the alkaline in their properties. They are insoluble in water, and incapable of being employed as detergents. They may be formed very readily by mixing common soap with a solution of an earthy salt; the alkali of the soap combines with the acid of the salt, while the earth and oil unite together and form an earthy soap. Hence the reason that all waters holding an earthy salt are unfit for washing. They decompose common soap, and form an earthy soap insoluble in water. These waters are well known by the name of hard waters. Hitherto the earthy soaps have been examined by Mr. Berthollet only.

Soap of lime. This soap may be formed by pouring lime-water into a solution of common soap. It is insoluble both in water and alcohol. Carbonat of fixed alkali decomposes it by compound affinity. It melts with difficulty, and requires a strong heat.

Soap of barytes and of strontian resemble almost exactly the soap of lime.

Soap of magnesia may be formed by mixing together solution of common soap and sulphat of magnesia. It is exceedingly white. It is unctuous, dries with difficulty, and preserves its whiteness after desiccation. It is insoluble in boiling water. Alcohol and fixed oil dissolve it in considerable quantity. Water renders its solution in alcohol milky. A moderate heat melts it; a transparent mass is formed, slightly yellow, and very brittle.

Soap of alumina may be formed by mixing together solutions of alum and of common soap. It is a flexible soft substance, which retains its suppleness and tenacity when dry. It is insoluble in alcohol, water, and oil. Heat easily melts it, and reduces it to a beautiful transparent yellowish mass.

Metallic oxides are capable of combining with oils by two different processes: 1. By mixing together a solution of common soap with a metallic salt. 2. By uniting the metallic oxide with the oil directly, either cold or by the assistance of heat. The first of these combinations is called a metallic soap; the second a plaster. See Plaster.

Soaps, *metallic.* These soaps have been examined by Mr. Berthollet; who has proposed some of them as paints, and others as varnishes; but it does not appear that any of them has been hitherto applied to these purposes.

1. Soap of mercury may be formed by mixing together a solution of common soap and of corrosive muriat of mercury. The liquor becomes milky, and the soap of mercury is gradually precipitated. This soap is viscid, not easily dried, loses its white colour when exposed to the air, and acquires a slate-colour, which gradually becomes deeper, especially if exposed to the sun or to heat. It dissolves very well in oil, but sparingly in alcohol. It readily becomes soft and fluid when heated.

2. Soap of zinc may be formed by mixing together a solution of sulphat of zinc and of soap. It is of a white colour, inclining to yellow. It dries speedily, and becomes friable.

3. Soap of cobalt, made by mixing nitrat of cobalt and common soap, is of a dull leaden colour, and dries with difficulty, though its parts are not conducted.

Mr. Berthollet observed, that towards the end of the precipitation there fell down some green coagula, much more consistent than soap of cobalt. These he supposed to be a soap of nickel, which is generally mixed with cobalt.

4. Soap of tin may be formed by mixing common soap with a solution of tin in nitro-muriatic acid. It is white. Heat does not fuse it like other metallic soaps, but decomposes it.

5. Soap of iron may be formed by means of sulphat of iron. It is of a reddish-brown colour, tenacious, and easily fusible. When spread upon wool, it sinks in and dries. It is easily soluble in oil, especially of turpentine. Berthollet proposes it as a varnish.

6. Soap of copper may be formed by means of sulphat of copper. It is of a green colour, has the feel of a resin, and becomes dry and brittle. Hot alcohol renders its colour deeper, but scarcely dissolves it. Ether dissolves it, liquefies it, and renders its colour deeper and more beautiful. It is very soluble in oils, and gives them a pleasant green colour.

7. Soap of lead may be formed by means of acetite of lead. It is white, tenacious, and very adhesive when heated. When fused it is transparent, and becomes somewhat yellow if the heat is increased.

8. Soap of silver may be formed by means of nitrat of silver. It is at first white, but becomes reddish by exposure to the air. When fused, its surface becomes covered with a brilliant iris; beneath the surface it is black.

9. Soap of gold is formed by means of muriat of gold. It is at first white, and of the consistence of cream. It gradually assumes a dirty purple colour, and adheres to the skin.

10. Soap of manganese is formed of sulphat of manganese. It is at first white, and then by absorbing oxygen it becomes red.

SOCAGE, an antient tenure, by which lands were held on condition of ploughing the lord's lands, and doing the operations of husbandry, at their own charges.

SOCCUS, in antiquity, a kind of high shoe, reaching above the ancle, worn by comedians, as the cothurnus was by tragedians.

SOCIETY. See ACADEMY.

SOCINIANS, in church history, a sect of christians, so called from their founder Faustus Socinus, a native of Sienna, in Italy. He, about the year 1574, began openly to declare against the catholic faith, and taught, 1. That the eternal father was the one only God; that the Word was no more than an expression of the godhead, and had not existed from all eternity; and that Jesus Christ was God no otherwise than by his superiority above all creatures, who were put in subjection to him by the Father. 2. That Jesus Christ was not a mediator between God and men, but sent into the world to serve as a pattern of their conduct; and that he ascended up to heaven only to take a journey thither. 3. That the punishment of hell will last but for a certain time, after which the body and soul will be destroyed. And 4. That it is not lawful for princes to make war. These four tenets were what Socinus defended with the greatest zeal. In other matters, he was a lutheran or a calvinist; and the truth is, that he did but refine upon the errors of all the antitrinitarians that went before him. The socinians spread extremely in Poland, Lithuania, and Transylvania.

SOCMEN. See SOCAGE.

SOCOME, is taken for a custom of grinding corn at the lord's mill; whence came the name or term of bond socome, by which the tenants were bound to it; and also love socome, where they did it voluntarily out of love to their lord.

SODA, called also fossil or mineral alkali, because it was thought peculiar to the mineral kingdom, was known to the antients (though not in a state of purity) under the names of νιτρον and nitrum.

It is found in large quantities combined with carbonic acid in different parts of the earth, especially in Egypt; and common salt is a compound of soda and muriatic acid. But the soda of commerce is obtained from the ashes of different species of the salsola, a genus of plants which grow upon the seashore, especially from the salsola soda, from which the alkali has obtained its name. The soda of commerce is also called barilla, because the plant from which it is obtained bears that name in Spain. Almost all the algæ, especially the fuci, contain also a considerable quantity of soda. The ashes of these plants are known in this country by the name of kelp; in France they are called varec.

The soda, or barilla of commerce, is far from being pure; besides carbonic acid it contains common salt, and several other foreign ingredients; but it may be obtained perfectly pure by the processes for purifying potass. (See that article.)

Soda and potass resemble each other so nearly, that they were confounded together till Du Hamel published his dissertation on common salt in the Memoirs of the French Academy for 1736. He first proved that the base of common salt is soda, and that soda is different from potass. His conclusions were objected to by Pott, but finally confirmed by Margraff in 1758.

Soda is of a greyish-white colour, and agrees exactly with potass in its taste, smell, and action upon animal bodies; but its specific gravity is only 1.336.

Heat produces on it exactly the same effects as upon potass. When exposed to the air, it absorbs moisture and carbonic acid, and is soon reduced to the consistence of paste; but it does not liquefy like potass; in a few days it becomes dry again, and crumbles into powder.

It has a strong affinity for water, dissolves in it like potass, and may also be obtained in crystals by evaporating its aqueous solution. It is not altered by light; nor does it combine with oxygen, hydrogen, azote, carbon, charcoal, or metals. Its action upon phosphorus and sulphur is the same with that of potass. The sulphuret and hydrogenated sulphuret of soda possess the properties of the sulphuret and hydrogenated sulphuret of potass, and are formed in the same manner. In its action on metals, metallic oxides, and in its affinities, it also agrees with potass. In short, the two fixed alkalies, in a state of purity, resemble each other very nearly in almost every particular. Its importance in manufactures is not inferior to that of potass. For several purposes, as for soap and glass, it answers even better than potass.

SOFFITA, or SOFFIT, in architecture, any plafond or ceiling formed of cross beams of flying cornices, the square compartments or pannels of which are enriched with sculpture, painting, or gilding.

SOFI, or SOPHI. See SOPHI.

SOFTENING. See PAINTING.

SOIL. See HUSBANDRY.

SOIT FAIT COMME IL EST DESIRE', *be it done as it is desired*, a form used when the king gives the royal assent to a private bill preferred in parliament.

SOL, in music, the fifth note of the gamut, ut, re, mi, fa, sol, la. See GAMUT.

SOL, or SOU, a French coin made up of copper mixed with a little silver, value the 23d part of our shilling.

SOL, the *sun*, in astronomy.

SOL, in the old chemistry, is gold.

SOLANDRA, a genus of plants belonging to the class of pentandria, and to the order monogynia. The calyx is bursting; the corolla elevate, funnel-formed, very large; berry four-celled, many-seeded. The only species is grandiflora. This genus was first named solandra in honour of Dr. Solander, by Murray, in the 14th edition of the Systema Vegetabilium. In Jamaica it is called the peach-coloured trumpet-flower.

SOLANUM, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 28th order, luridæ. The calyx is inferior; the corolla is rotate and monophyllous; the fruit a berry, bilocular, and containing many small and flat seeds. Of this genus there are 93 species, most of them natives of the East and West Indies, the most remarkable of which are the following:

1. The dulcamora, woody nightshade a native of Britain and of Africa, is a slender climbing plant, rising to six or more feet in height. The leaves are generally oval, pointed, and of a deep-green colour; the flowers hang in loose clusters, of a purple colour, and divided into five pointed segments. The calyx is purple, persistent, and divided into five; the berry, when ripe, is red, and contains many flat yellowish seeds. It grows in hedges well supplied with water, and flowers about the end of June. On chewing the roots, we first feel a bitter, then a sweet taste: hence the name. The berries are said to be poisonous, and may easily be mistaken by children for currants. The stipites or younger branches are directed for use, and may be employed either fresh or dried; they should be gathered in the autumn. This plant is generally given in decoction or infusion. Several authors take notice, that the dulcamara partakes of the milder powers of the nightshade, joined to a resolvent and saponaceous quality; hence it promotes the secretions of urine, sweat, the menses, and lochia. It is recommended in a variety of disorders; but particularly in rheumatism, obstructed menses, and lochia; also in some obstinate cutaneous diseases.

2. The nigrum, garden nightshade, common in many places in Britain about dunghills and waste places. It rises to about two feet in height. The stalk herbaceous; the leaves alternate, irregularly oval, indented, and clothed with soft hairs. The flowers are white; the berries black and shining. It appears to possess the deleterious qualities of the other nightshades in a very high degree, and even the smell of the plant is said to cause sleep. The berries are equally poisonous with the leaves, causing cardialgia and delirium, and violent distortions of the limbs in children. Mr. Getaker, in 1757, recommended its internal use in old sores, in scrofulous and cancerous ulcers, cutaneous eruptions, and in dropsies. He says, that one grain infused in an ounce of water, sometimes produced a considerable effect; that in the dose of two or three grains it seldom failed to evacuate the first passages, to increase very sensibly the discharges by the skin and kidneys, and sometimes to occasion head-ache, drowsiness, giddiness, and dimness of sight. Mr. Broomfield declares, that in cases in which he tried the solanum they were much aggravated by it; and that in one case in the dose of one grain it proved mortal to one of his patients; therefore he contends its use is prejudicial. This opinion seems tacitly to be confirmed, as it is now never given internally. In antient times it was employed externally as a discutient and anodyne in some cutaneous affections, tumefactions of the glands, ulcers, and disorders of the eyes. The solanum nigrum ε rubrum, a native of the West Indies, is called guma by the negroes. It is so far from having any deleterious quality, that it is daily served up at table as greens or spinach. It has an agreeable bitter taste.

3. Lycopersicum, the love-apple, or tomato, cultivated in gardens in the warmer parts of Europe, and in all tropical countries. The stalk is herbaceous; the leaves pinnated, oval, pointed, and deeply divided. The flowers are on simple racemi; they are small and yellow. The berry is of the size of a plum; they are smooth, shining, soft; and are either of a yellow or reddish colour. The tomato is in daly use; being either boiled in soups or broths, or served up boiled as garnishes to flesh-meat.

4. Melongena, the egg plant, or vegetable egg. This is also cultivated in gardens, particularly in Jamaica. It seldom rises above a foot in height. The fruit is as big as, and

very like, the egg of a goose. It is often used boiled as a vegetable along with animal food or butter, and supposed to be aphrodisiac and to cure sterility.

5. Longum. This plant is also herbaceous, but grows much ranker than the foregoing. The flowers are blue: and the fruit is six or eight inches long, and proportionally thick. It is boiled and eaten at table as the egg-plant.

6. Tuberosum, the common potatoe. It was introduced by sir Walter Raleigh, and first cultivated in Ireland about the year 1600. Large fortunes have been made by the culture of potatoes at Westham in Essex.

SOLDANELLA, in botany, a genus of plants of the class of pentandria, and order of monogynia, and in the natural system arranged under the 21st order, preciæ. The corolla is campanulated; the border being very finely cut into a great many segments. The capsule is unilocular, and its apex polydentate. There is one species.

SOLDER, SODDER, or SODER, a metallic or mineral composition used in soldering or joining other metals. Solders are made of gold, silver, copper, tin, bismuth, and lead; usually observing, that in the composition there shall be some of the metal that is to be soldered mixed with some higher and finer metals. Goldsmiths usually make four kinds of solder, viz. solder of eight, where to seven parts of silver there is one of brass or copper; solder of six, where only a sixth part is copper; solder of four, and solder of three. It is the mixture of copper in the solder that makes raised plate come always cheaper than flat.

As mixtures of gold with a little copper are found to melt with less heat than pure gold itself, these mixtures serve as solders for gold: two pieces of fine gold are soldered by gold that has a small admixture of copper; and gold alloyed with copper is soldered by such as is alloyed with more copper. The workmen add a little silver as well as copper, and vary the proportions of the two to one another, so as to make the colour of the solder correspond as nearly as may be to that of the piece. A mixture of gold and copper is also a solder for fine copper as well as for fine gold. Gold being particularly disposed to unite with iron, proves an excellent solder for the finer kinds of iron and steel instruments.

The solder used by plumbers is made of two pounds of lead to one of block-tin. Its goodness is tried by melting it, and pouring the size of a crown piece on a table; for, if good, there will arise little bright shining stars in it. The solder for copper, is made like that of the plumbers; only with copper and tin; and for very nice works, instead of tin, they sometimes use a quantity of silver. Solder for tin is made of two-thirds of tin and one of lead, or of equal parts of each; but where the work is any thing delicate, as in organ-pipes, where the juncture is scarcely discernible, it is made of one part of bismuth and three parts of pewter. The pewterers use a kind of solder made with two parts of tin and one of bismuth; this composition melts with the least heat of any of the solders.

Silver solder is that which is made of two parts of silver and one of brass, and used in soldering those metals. Spelter solder is made of one part of brass and two of spelter or zinc, and is used by the braziers and coppersmiths for soldering brass, copper, and iron. This solder is improved by adding to each ounce of it one pennyweight of silver; but as it does not melt without a considerable degree of heat, it cannot be used when it is inconvenient to heat the work red-hot; in which case copper and brass are soldered with silver.

Though spelter solder is much cheaper than silver solder, yet workmen in many cases prefer the latter. And Mr. Boyle informs us, that he has found it to run with so moderate a heat, as not much to endanger the melting of the delicate parts of the work to be soldered; and if well made, this silver solder will lie even upon the ordinary kind itself; and so fill up those little cavities that may chance to be left in the first operation, which is not easily done without a solder more easily fusible than the first made use of.

SOLDERING, the joining and fastening together of two pieces of the same metal, or of two different metals, by the fusion and application of some metallic composition on the extremities of the metals to be joined. To solder upon silver, brass, or iron: take silver, five pennyweights; brass, four pennyweights; melt them together for soft solder, which runs soonest. Take silver, five pennyweights; copper, three pennyweights; melt them together for hard solder. Beat the solder thin, and lay it on the place to be soldered, which must be first fitted and bound togerher with wire as occasion requires; then take borax in powder, and temper it like pap, and lay it upon the solder, letting it dry; then cover it with live coals, and blow, and it will run immediately.; take it presently out of the fire, and it is done. It is to be observed, that if any thing is to be soldered in two places, which cannot well be done at one time, you must first solder with the harder solder, and then with the soft; for, if it is first done with the soft, it will unsolder again before the other is softened. Let it be observed, that if you would not have your solder run about the piece that is to be soldered, you must rub such places over with chalk. In the soldering either of gold, silver, copper, or either of the metals above mentioned, there is generally used borax in powder, and sometimes rosin. As to iron, it is sufficient that it be heated red-hot, and the two extremities thus hammered together, by which means they will become incorporated with each other. For the finer kinds of iron and steel instruments, however, gold proves an excellent solder. This metal will dissolve twice or thrice its weight of iron in a degree of heat very far less than that in which iron itself melts; hence if a small plate of gold is wrapped round the parts to be joined, and afterwards melted by a blowpipe, it strongly unites the pieces together without any injury to the instrument, however delicate.

SOLEÆ, among the Romans, a kind of sandals or slippers which covered only the sole of the feet, and were bound on with thongs of leather, instead of which the women and the effeminate ones of the other sex tied them on with purple-coloured ribbons, or such as were variously adorned with gold and silver.

SOLECISM, *soloecismus*, in grammar, a false manner of speaking contrary to the use of language and the rules of grammar, either in respect of declension, conjugation, or syntax.

SOLEN, *razor sheath*, or *knife-handle shell*, a genus belonging to the class of vermes, and order of testacea. The animal is an ascidia. The shell is bivalve, oblong, and opening at both sides; the hinge has a tooth shaped like an awl, bent back, often double, not inserted into the opposite shell; the rim at the sides somewhat worn away, and has a horny cartilaginous hinge. There are 23 species; three of them, viz. the siliqua, vagina, and ensis, are found on the British coasts, and lurk in the sand near the low-water mark in a perpendicular direction. When in want of food they elevate one end a little above the surface, and protrude their bodies far out of the shell. On the approach of danger they dart deep into the sand, sometimes two feet at least. Their place is known by a small dimple on the surface. Sometimes they are dug out with a shovel; at other times they are taken by striking a barbed dart suddenly into them. When the sea is down, these fish usually run deep into the sand; and to bring them up, the common custom is to throw a little salt into the holes, on which the fish raises itself, and in a few minutes appears at the mouth of its hole. When half the shell is discovered, the fisherman has nothing more to do than to take hold of it with his fingers and draw it out; but he must be cautious not to lose the occasion, for the creature does not continue a moment in that state; and if by any means the fisherman has touched it, and let it slip away, it is gone for ever; for it will not be decoyed again out of its hole by salt; so that there is then no way of getting it but by digging under it, and throwing it up with the sand. The fish has two pipes, each composed of four or five rings or portions of a hollow cylinder, of unequal lengths, joined one to another; and the places where they join are marked by a number of fine streaks or rays. The reason why the salt causes these creatures to come up out of their holes, is, that it gives them violent pain, and even corrodes these pipes. This is somewhat strange, as the creature is nourished by means of salt water; but it is very evident, that if a little salt is strewed upon these pipes in a fish taken out of its habitation, it will corrode the joinings of the rings, and often make one or more joints drop off; the creature, to avoid this mischief, arises out of its hole, and throws off the salt, and then retires back again. The use of these pipes to the animal is the same with that of many other pipes of a like kind in other shell-fish; they all serve to take in water: they are only a continuation of the outer membrane of the fish, and serve indifferently for taking in and throwing out the water, one receiving and the other discharging it, and either answering equally well to their purpose.

This fish was used as food by the antients; and Athenæus, from Sophron, speaks of it as a great delicacy, and particularly grateful to widows. It is often used as food at present, and is brought up to table fried in eggs.

SOLFAING, or SOLMIZATION, the art of sounding the notes, together with the corresponding syllables of the gamut. This preparatory exercise, so necessary to sight-singing, and which, by uniting in the mind of the practitioner the ideas of the different syllables with those of the intervals, facilitates the recollection of the several sounds, was of very antient adoption.

Guido having substituted his hexachord in place of the antient tetrachord, adopted at the same time for his solmization six other syllables, ut, re, mi, fa, sol, la, taken from the hymn of St. John the Baptist.

Of the seven notes in the French scale, only four were for a while used by us, as mi, fa, sol, la; but now we, as well as the Italians, employ the first six, with the exception of changing ut for do, as a softer and more vocal syllable. By applying these syllables to the several notes, the practitioner not only utters the sound with more fulness, ease, and freedom, but, by the association of ideas, attains a ready recollection of the places of the tones and semitones, and by feeling the relation between the syllabic and the musical sounds, acquires the power of expressing them with truth and certainty.

SOLICITOR, a person employed to take care of, and manage, suits depending in the courts of equity, and those of the lower sort are too often made use of to the damage of the people, and the increase of champerty and maintenance.

Solicitors are within the statute to be sworn and admitted by the judges, before they are allowed to practise in our courts, in like manner as attorneys.

SOLID. Geometricians define a solid to be the third species of magnitude, or that which has three dimensions, viz. length, breadth, and thickness or depth.

A solid may be conceived to be formed by the revolution, or direct motion, of a superficies of any figure whatever, and is always terminated or contained under one or more planes or surfaces, as a surface is under one or more lines.

Solids are commonly divided into regular and irregular. The regular solids are those terminated by regular and equal planes, and are only five in number, viz. the tetrahedron, which consists of four equal triangles; the cube, or hexahedron, of six equal squares; the octahedron, of eight equal triangles; the dodecahedron, of twelve; and the icosihedron, of twenty equal triangles. See TETRAHEDRON, CUBE, &c.

SOLID *of least resistance*. Sir Isaac Newton, in his Principia, shews that if there is a curve figure, as DNFG, (Plate Miscel. fig. 218.) of such a nature, that from any point, as N, taken in its circumference, a perpendicular NM is let fall on the axis AB; and if from a given point, as G, there is drawn the right line GR, parallel to a tangent to the curve in the point N, cutting the axis produced in R, and the proportion then is, as $NM : GR :: GR^3 : 4 BG \times GR$; the solid generated by the revolution of this curve about its axis AB, when moved swiftly in a rare and elastic medium, will meet with less resistance from the medium, than any other circular solid whatever, of the same length and breadth.

SOLID ANGLE, is that formed by three or more planes meeting in a point, like the point of a diamond well cut.

SOLID NUMBERS, are those which arise from the multiplication of a plane number, by any other whatever; as 18 is a solid number made of 6 (which is plane), multiplied by 3; or of 9 multiplied by 2.

SOLID PROBLEM, in mathematics, is one which cannot be geometrically solved unless by the intersection of a circle and a conic section; or by the intersection of two other conic sections, besides the circle.

As to describe an isosceles triangle on a given right line, whose angle at the base shall be triple to that at the vertex.

This will help to inscribe a regular heptagon in a given circle; and may be resolved by the intersection of a parabola and a circle.

This problem also helps to inscribe a nonagon in a circle; and may be solved by the intersection of a parabola, and an hyperbola between its asymptotes, viz.

To describe an isosceles triangle, whose angle at the base shall be quadruple of that at the vertex.

And such a problem as this has four solutions, and no more; because two conic sections can cut one another but in four points.

SOLIDAGO, *golden rod*, a genus of plants of the class of syngenesia, and the order of polygamia superflua, and in the natural system ranging under the 49th order, compositæ. The receptacle is naked; the pappus simple; the radii are commonly five; the scales of the calyx are imbricated, and curved inward. There are 30 species. Among these there is only one which is a native of Britain; the virgaurea, or common golden rod, which grows frequently in rough mountainous pastures and woods. There is a variety of this species called cambrica, to be found on rocks, from six inches to a foot high.

SOLIDITY is that property of matter, by which it excludes all other bodies from the place which itself possesses.

SOLITARIES, a denomination of nuns of St. Peter of Alacantara, instituted in 1676, the design of which is to imitate the severe penitent life of that saint: thus they are to keep a continual silence, never to open their mouths to any body; employ their time wholly in spiritual exercises, and leave the temporal concerns to a number of maids, who have a particular superior in a separate part of the monastery; they always go barefooted, without sandals; gird themselves with a thick cord, and wear no linen.

SOLO, in music, a term used in pieces consisting of several parts, to mark those that are to perform alone: it is sometimes denoted by S.

When two or three parts play, or sing, separately from the grand chorus, they are called a dio soli, a tre soli, &c.

SOLSTICE. See ASTRONOMY.

SOLUTION, in chemistry, denotes an intimate mixture, or perfect union, of solid bodies with fluids, so as seemingly to form one homogeneous liquor. The dissolving fluid is termed the solvent or menstruum.

A solution is distinguished from a mixture by being perfectly clear, though not always colourless, and from the parts not separating when set at rest. See CHEMISTRY.

SOLUTION, in algebra and geometry, is the answering a question, or the resolving any problem proposed.

SOLUTION *of continuity*, in surgery, is the separation of the natural cohesion of the solid parts of the body, by a wound.

SOMMETI, a mineral named from the mountain Somma, where it was first found. It is usually mixed with volcanic productions. It crystallizes in prisms, sometimes terminated by pyramids. Colour white, and somewhat transparent. It cuts glass. The specific gravity is 3.27. Infusible by the blowpipe; and according to Vauquelin, it is composed of

49	alumina
46	silica
2	lime
1	oxide of iron
98.	

SONATA, in music, a piece, or composition, intended to be performed by instruments only; in which sense it stands opposed to cantata, or a piece designed for the voice.

There are several kinds of sonatas. The Italians, however, reduce them principally to two: the sonata da camera, or chamber sonata; and the sonata da chiesa, or church sonata. The sonata, of whatever kind, generally opens with an adagio; and after two or three movements of various descriptions, concludes with an allegro, or a presto. This definition of a sonata, however, rather belongs to what is called the antient than to the modern music, in which the sonata is chiefly composed as a lesson or exercise for a single instrument.

SONCHUS, *sow-thistle*, a genus of plants belonging to the class of syngenesia, and to the order of polygamia æqualis, and in the natural system ranged under the 49th order, compositæ. The receptacle is naked; the calyx is imbricated, bellying, and conical; the down of the seed is simple, sessile, and very soft; the seed is oval and pointed. There are 19 species; four of these are natives of Britain: 1. Palustris, marsh sow-thistle. 2. Arvensis, corn sow-thistle. 3. Oleraceus, common sow-thistle. 4. Alpinus, blue-flowered sow-thistle. All of them nefarious weeds.

SONG, in poetry, a little composition, consisting of easy and natural verses, set to a tune in order to be sung. See POETRY.

SONG, in music, is applied in general to a single piece of music, whether contrived for the voice or an instrument.

SONG *of birds*, is defined by the honourable Daines Barrington to be a succession of three or more different notes, which are continued without interruption, during the same interval, with a musical bar of four crotchets in an adagio movement, or whilst a pendulum swings four seconds. It is affirmed by this author that the notes of birds are no more innate than language in man, and that they depend upon imitation, as far as their organs will enable them to imitate the sounds which they have frequent opportunities of hearing; and their adhering so steadily, even in a wild state, to the same song, is owing to the nestlings attending only to the instruction of the parent bird, whilst they disregard the notes of all others that may perhaps be singing round them.

Birds in a wild state do not commonly sing above 10 weeks in the year; whereas birds that have plenty of food in a cage, sing the greatest part of the year; and we may add, that the female of no species of birds ever sings. This is a wise provision of nature, because her song would discover her nest. In the same manner, we may rationally account for her inferiority in plumage. The faculty of singing is confined to the cock birds; and accordingly Mr. Hunter, in dissecting birds of several species, found the muscles of the larynx to be stronger in the nightingale than in any other bird of the same size; and in all those instances where he dissected both cock and hen, the same muscles were stronger in the cock.

Some have ascribed the singing of the cock bird in the spring solely to the motive of pleasing his mate during incubation; others, who allow that it is partly for this end, believe it is partly owing also to another cause, viz. the great abundance of plants and insects in the spring, which, as well as seeds, are the proper food of singing birds at that time of the year.

Mr. Barrington remarks, that there is no instance of any singing bird which exceeds our blackbird in size; and this, he supposes, may arise from the difficulty of its concealing itself. if it called the attention of its enemies, not only by its bulk, but by the proportionable loudness of its notes. This writer further observes, that some passages of the song in a few kinds of birds, correspond with the intervals of our musical scale, of which the cuckoo is a striking and known instance: but the greater part of their song cannot be reduced to a musical scale; partly, because the rapidity is often so great, and it is also so uncertain when they may stop, that we cannot reduce the passages to form a musical bar in any time whatsoever; partly, also, because the pitch of most birds is considerably higher than the most shrill notes of those instruments which have the greatest compass; and principally, because the intervals used by birds are commonly so minute, that we cannot judge of them from the more gross intervals into which we divide our musical octave. This writer apprehends that all birds sing in the same key.

Most people, who have not attended to the notes of birds, suppose that every species sing exactly the same notes and passages; but this is by no means true, though it is admitted that there is a general resemblance. Thus the London bird-catchers prefer the song of the Kentish goldfinches, and Essex chaffinches; and some of the nightingale-fanciers prefer Surry birds to those of Middlesex.

Of all singing birds, the song of the nightingale has been most universally admired; and its superiority (deduced from a caged bird) consists in the following particulars: its tone is much more mellow than that of any other bird; though at the same time, by a proper exertion of its musical powers, it can be very brilliant. Another point of superiority is its continuance of song without a pause, which is sometimes no less than 20 seconds; and when respiration becomes necessary, it takes it with as much judgment as an opera-singer. The sky-lark in this particular, as well as in compass and variety, is only second to the nightingale. The nightingale also sings (if the expression may be allowed) with superior judgment and taste.

Mr. Barrington has observed, that his nightingale, which was a very capital bird, began softly like the antient orators; reserving its breath to swell certain notes, which by these means had a most astonishing effect. This writer adds, that the notes of birds, which are annually imported from Asia, Africa, and America, both singly and in concert, are not to be compared to those of European birds.

The following table, formed by Mr. Barrington, agreeably to the idea of M. de Piles, in estimating the merits of painters, is designed to exhibit the comparative merit of the British singing birds; in which 20 is supposed to be the point of absolute perfection.

	Mellowness of tone.	Sprightly notes	Plaintive notes.	Compass.	Execution.
Nightingale - -	19	14	19	19	19
Sky-lark - - -	4	19	4	18	18
Wood-lark - -	18	4	17	12	8
Tit-lark - - -	12	12	12	12	12
Linnet - - -	12	16	12	16	18
Goldfinch - -	4	19	4	12	12

Black-cap, or Norfolk mock-nightingale	14	12	12	14	14

SONNERATIA, a genus of plants belonging to the class of icosandria, and to the order of monogynia. The calyx is cut into six segments; the petals are six; the capsule is multilocular and succulent; and the cells contain many seeds. The only species is the acida, a tree of New Guinea.

SONNET. See POETRY.

SOOT, a substance deposited from the flame of burning vegetables. It consists chiefly of carbon, which, for want of complete contact with the air, could not be consumed, and is partly carried off mechanically with the smoke, and partly precipitated.

SOPHORA, a genus of plants belonging to the decandria monogynia class, with a papilionaceous flower: its fruit is a very long and slender unilocular pod, containing a great many roundish seeds. It agrees in every thing with the diadelphia and papilionaceous plants, except that its stamina are distinct and separate. There are 25 species, all foreign shrubs.

SORBUS, *service-tree*, a genus of plants belonging to the class icosandria, and to the order of trigynia. The calyx is quinquefid; the petals are five; the berry is below the flower, soft, and containing three seeds. There are three species; the aucuparia, domestica, and hebrida.

1. The aucuparia, mountain-ash, quicken-tree, quick-beam, or roan-tree, rises with a straight upright stem and regular branching head, 20 or 30 feet high or more, covered with a smooth greyish-brown bark; pinnated leaves, and large umbellate clusters of white flowers at the sides and ends of the branches, succeeded by clusters of fine red berries, ripe in autumn and winter. There is a variety with yellow-striped leaves. This species grows wild in many parts of this island, in mountainous places, woods, and hedge-rows, often growing to the size of timber; and is admitted into most ornamental plantations, for the beauty of its growth, foliage, flowers, and fruit..

2. The domestica, or cultivated service-tree, with eatable fruit, grows with an upright stem, branching 30 or 40 feet high, or more, having a brownish bark, and the young shoots in summer covered with a mealy down: pinnated leaves of eight or ten pair. This tree is a native of the southern warm parts of Europe, where its fruit is used at table as a dessert; and it is cultivated here in many of our gardens as a fruit-tree, and as an ornament to diversify hardy plantations.

3. The hebrida, or mongrel service-tree of Gothland, grows 20 or 30 feet high; it has half pinnated leaves, very downy underneath; and clusters of white flowers, succeeded by bunches of round reddish berries in autumn.

SOREX, *shrew*, a genus of quadrupeds of the order feræ. The generic character is, front teeth in the upper jaw two, long, bifid; in the lower, two or four, the intermediate ones shorter; canine teeth, several on each side; grinders cuspidated.

The genus sorex, of which there are 17 species, in its general appearance bears a great resemblance to the mouse tribe; but the structure, number, and situation of the teeth, prove it to constitute a very different set of animals, which are evidently rather carnivorous than frugivorous. It is more closely allied to the genus talpa; insomuch that these two genera may be considered as linked to each other by intermediate species, which in habit resemble the one genus, and in teeth the other. It is owing to this circumstance that Linnæus, in the twelfth edition of the Systema Naturæ, has placed one or two genuine species of talpa in the genus sorex. The most common species of sorex in this country is the S. araneus, commonly known by the name of the shrew-mouse.

1. Sorex araneus. This little animal, which is perhaps the smallest of the European quadrupeds, is a very common inhabitant of our fields and gardens, and measures about two inches and a half, and the tail one and a half. Its colour is nearly similar to that of a mouse, but of a somewhat more ferruginous tinge; and the animal is readily distinguished by its long and sharp snout; the eyes are small, and almost hid in the fur. It feeds on roots, grain, insects, and almost any kind of neglected animal substance. It has a very strong and unpleasant smell; and it is remarkable that cats will kill but not eat it. Mr. Pennant observes that there seems to be an annual mortality among these little animals every autumn; numbers of them being found dead at that season by paths and in the fields. It inhabits most parts of Europe, and is also said to be found in Siberia and Kamtschatka. It breeds in holes, under banks, among moss, &c. and is said to produce several young at a time.

2. Sorex moschatus, musk-shrew. This is a very singular species, which, though ex-

tremely common in some of the northern parts of Europe and Asia, does not seem to have been very distinctly understood by modern naturalists.

According to Dr. Pallas, it chiefly inhabits the river Wolga and the adjacent lakes, from Novogorod to Saratof; and is not found in Russia, nor does its existence in Lapland seem well ascertained. It is said to be very seldom seen on land; confining itself to lakes and rivers, in the banks of which it occasionally burrows to a great distance. The general length of the animal is about seven inches from nose to tail, and of the tail eight inches: but it is sometimes found of a larger size. The tail, except at its base, is perfectly naked, marked out into scaly divisions, and is of a brown colour; it is also of a laterally compressed form, and gradually tapers to the extremity; near the base of the tail are situated several small follicles, or glandular receptacles, in which is secreted a yellowish fluid, resembling in smell the strongest civet; of this substance about the quantity of a scruple may, it is said, be obtained from each animal.

These creatures are said sometimes to be seen swimming about in considerable numbers on the surface of lakes and rivers, and may often be heard to snap their mouths with a sound not unlike that of a duck; feeding on worms, leeches, water-insects, &c. as well as occasionally on vegetable substances.

In some particulars this animal makes a distant approach to that most singular of quadrupeds, the platypus.

The musk-shrew is a slow-paced animal, and easily taken, if accidentally found on land. The skins are said to be sold in Russia to put into chests in order to drive away moths; and so common is the animal in the neighbourhood of Nizney Novogorod, that the peasants are said to bring five hundred apiece to market, where they are sold for a ruble per hundred.

In the twelfth edition of the Systema Naturæ this animal is placed in the genus castor or beaver, under the title of castor moschatus. See Plate Nat. Hist. fig. 368.

3. Sorex radiatus, Canada shrew. This animal may with great propriety be termed sorex radiatus, since the snout, which is long and slender, has a dilated cartilaginous extremity, furnished with a circular series of sharp-pointed processes or soft tendrils, disposed in the manner of the rays in a spur. The whole animal is of a long form, and its habit immediately pronounces it to belong to the genus sorex, and not to that of talpa. Its body is longish, and covered with black coarsish hair; the feet far less than those of a mole; the eyes hid under the skin; the snout edged on each side with upright vibrissæ; the radiated tentacula at the end of the nose are of a bright rose-colour, and moveable at the pleasure of the animal, so as either to be brought together into a tubular form, or expanded in the form of a star.

It is said to inhabit Canada, but not to be very common there. It occasionally burrows somewhat in the manner of a mole, but far less strongly, or more slowly, and is said to pass a considerable portion of its life beneath the surface of the snow.

4. Sorex cærulescens, perfuming shrew, measures from nose to tail near eight inches; and the tail is about three inches and a half long. This animal diffuses a musky smell, so extremely powerful as to penetrate almost every substance which it touches. It inhabits fields, but is said sometimes to come into houses. It is found in the East Indian islands, as well as in India, occurring in Java, &c. &c. and is said to feed chiefly on rice.

5. Sorex minutus, minute shrew, is an extremely small animal, which inhabits moist places in Siberia, and makes its nest of lichens and mosses under the roots of trees, living on grains and seeds, &c. It is of a subferruginous brown colour above, and whitish below; the head is large; the snout very long and slender, and beset with a row of long whiskers on each side, reaching as far as the eyes. It has no tail; the eyes are small, and the ears short and naked. It is said to run swiftly, and to have a voice like that of a bat. It weighs about a dram.

SORITES, in logic, a species of reasoning in which a great number of propositions are so linked together, that the predicate of the one becomes continually the subject of the next following, till at last a conclusion is formed by bringing together the subject of the first proposition and the predicate of the last: such is the following argument: "God is omnipotent; an omnipotent being can do every thing possible; a being that can do every thing possible, can do whatever involves not a contradiction; therefore, God can do whatever involves not a contradiction."

SORREL. See Rumex.

SOUND is produced by a vibrating motion, excited in a sonorous body by a blow or a shock from another body; and the same motion is communicated by this sonorous body to the air which surrounds it, and transmitted by this fluid to the ear, which is an organ admirably adapted to receive its impression.

From this definition it follows, that sound should be considered in three different views; first, with respect to the sonorous body; which produces it; secondly, as to the medium which transmits it; and, thirdly, as to the organ which receives the impression.

Those bodies are properly called sonorous which afford a sound distinct, and of some duration; such as bells, the strings of a violin, &c. and not those which cause only a confused noise, such as a stone produces when it falls upon a pavement. When bodies are, strictly speaking, sonorous, they are necessarily elastic, as will be afterwards proved; and their sound, as to its force and duration, is proportionate to their vibrations.

Suppose, for example, the bell of a clock to be struck by any solid body, a kind of undulating or tremulous motion is imparted to the minute particles; and this motion may be even perceived by the hand or fingers when applied to the bell.

To understand this more completely, let us conceive that a bell is composed of a series of circular zones, decreasing in diameter all the way to its top, each of which may be considered as a flat ring, composed of as many concentric circles as its thickness will admit of. If this ring is struck at the point *a* (Plate Miscel. fig. 219), the part so struck tends towards *g*, and at the same time the parts *b* and *d* tend towards *i* and *m*, and this action in these parts necessarily causes the point *c* to approach towards *e*. By their elastic power, however, these parts presently regain the position in which they were before the bell was struck; but as they return with an accelerated force, they generally go beyond the point where they ought to rest. The part *a*, therefore, after having returned from *g* to *a*, tends towards *f*, the part *c* towards *h*, and the parts *b* and *d* towards *k* and *l*; whence it happens that the bell, at first of a circular form, really becomes alternately elliptical in two different directions; it follows then, that in those parts where the curvature is the greatest, their exterior points depart from each other.

The same circumstance happens to the musical chord of a harp, or other stringed instrument, when it is touched: for, in order to become angular, as BCD or BED (fig. 220) it is necessary that the string be stretched or lengthened, and consequently its particles be in some measure removed from the point of contact.

There are then two vibrations which take place in sonorous bodies: the general vibration, which changes the form of the body; and the particular vibration, which affects the minute particles, in consequence of the former. M. de la Hire has proved, that the sound is not owing to the general vibration, but rather to the vibration of the particles: for whenever the two vibrations can be separated, it is found that the former produces no sound; but when the general vibration is accompanied with a vibration of the particles, it is the latter that regulates the duration, the force, and the modulation of the sound; if, on the contrary, these vibrations are stopped or interrupted by touching the sonorous body, the sound immediately ceases. On this account clock-makers attach to the hammer which strikes the bell of the clock a small spring, which elevates it again the moment it has struck, and prevents it from remaining upon the bell, which would considerably deaden or destroy the sound.

Acute sounds are produced, when the vibrations of the sounding body are more frequent; grave or deep sounds, when they are less so; no medium between acute and grave sounds can be found. Sonorous bodies are said to be in unison when they vibrate with the same frequency; when one vibrates twice as fast as the other, they differ by an octave; and other ratios, with respect to the quickness of vibration, are distinguished by other names. Chords which are short and tightly stretched, produce acute sounds; those which are long and lax, grave sounds.

The motion or vibration of bodies at a distance from us would not affect our sense of hearing without the medium of some other body, which receives an impulse from this motion, and communicates the vibration to our organs. Thus a hard blow upon an anvil or upon a bell could not be heard by us, even at a very small distance, if there was not a medium between those objects and us capable of transmitting the vibrations to our auditory nerves. Elastic fluids are the most effective mediums for this purpose, and consequently the air is the most common vehicle of sound; which is very easily proved by ringing a bell under the receiver of an air-pump, the sound it affords being found gradually to diminish as the air becomes exhausted, till at length it ceases to be heard at all. That the air is capable of being agitated with great force, appears from the violent concussions produced by explosions of gunpowder, as well as from the power, which some persons are known to possess, of breaking drinking-glasses, by means of their voice, when sounded in unison with the note which the glass would have produced when struck. The tremulous motion excited in the air by sounding bodies, has been supposed analogous to the successive rings which are produced by disturbing the surface of the water. This hypothesis, however, was disproved by the observation that sounds, whether weak or loud, always travel with the same velocity, which does not hold true with respect to the rings on the surface of water, since these move faster or slower according to the force of the cause which excited them.

Every sound is rendered stronger or weaker, and may be heard at a greater or less distance, according to the density or rarity of that elastic fluid by which it is propagated. According to Mr. Hauksbee, who has made deep researches into this branch of philosophy, when air has acquired twice its common density it transmits sound twice as far as common air; whence he reasonably concludes, that sound increases, not only in direct proportion to the density of the air, but in proportion to the square of this density.

If sound was propagated in an elastic fluid more dense than the air, it would be carried proportionably farther. I have proved this, says M. Brisson, by putting a sonorous body into carbonic acid gas or fixable air, the density of which is about one-third more than that of atmospherical air; the consequence was, that at that time, and in that situation, the sound was very considerably increased. For the same reason, the dryness of the air, which increases its density, has a considerable effect in rendering sound louder and more audible. Sound is also much increased by the reverberation of the pulses of the air from those surrounding bodies against which they strike, whence it happens that music is so much louder in a close apartment than in the open air.

Elastic fluids are, however, not the only medium through which sound may be transmitted; for it may be propagated by means of water and other liquors, which may be proved by immersing a sonorous body in water; but it must be observed, that in this case the sound will be less perceptible, and will not extend to so great a distance; the cause of this diminution is, because mediums for the transmission of sound should be elastic, and that is a property which water and other liquors possess only in a very restricted degree.

Sound is also transmitted by solid bodies, provided they possess a sufficient degree of elasticity to produce this effect.

Light, we have already seen, is projected or reflected with incredible velocity; but sound is transmitted much more slowly, and its progression is very perceptible to our senses. The flash from a cannon, or even a musket, may be seen some seconds before the sound reaches our ears. As the motion of light, therefore, is instantaneous with respect to any moderate distance, this has been the common means employed for ascertaining the progress of sound. Sir Isaac Newton observes that "all sounding bodies propagate their motions on all sides by successive condensations and relaxations; that is, by an alternate progression and return of the particles;" and these vibrations, when communicated to the air, are termed pulses of sound.

All pulses move equally fast. This is proved by experiment; and it is found that they pass about one thousand one hundred and forty-two feet in a second, whether the sound is loud or low, grave or acute.

Some curious experiments were made, relative to the propagation of sound, by Messieurs De Thury, Maraldi, and De la Caille, upon a line fourteen thousand six hundred and thirty-six fathoms in length, having the tower of mount Lhéri at one end, and the pyramid of Montmartre at the other extremity of that distance: their observatory was placed between those two objects. The results of their observations were these: 1st. That sound moves one hundred and seventy-three fathoms, French, in a second, when the air is calm. 2d. That sound moves with the same degree of swiftness whether it is strong or weak; for these gentlemen observed, that the discharge of a box of half a pound of gunpowder exploded at Montmartre was heard at mount Lhéri in the same space of time as the report of a great gun charged with nearly six pounds of powder. 3d. That the motion of sound is uniform; that its velocity neither accelerates nor diminishes through all the intervals of its progress, as is the case with almost every other species of motion. 4th. That the velocity of sound is the same, whether a cannon is placed towards the person who hears its report, or turned a contrary way; in other words, a great gun fired from the Tower of London eastward, would be heard at Westminster in the same interval of time as if it was discharged towards the latter place. And if the gun was discharged in a direction perpendicular to the horizon, it would be heard as soon as if discharged in a right line towards the hearer. By other experiments, however, the progress of sound appears to be impeded by a strong wind, so that it travels at the rate of about one mile slower in a minute against a strong wind than with it.

A knowledge of the progression of sound is not an article of mere sterile curiosity, but in several instances useful; for by this we are enabled to determine the distance of ships or other moving bodies. Suppose, for example, a vessel fires a gun, the sound of which is heard five seconds after the flash is seen; as sound moves 1142 English feet in one second, this number multiplied by 5, gives the distance of 5710 feet. The same principle has been applied to storms of lightning and thunder, as to calculating the distance of it from us. See Electricity.

The waves or pulses of sound being reflexible in their course when they meet with an extended solid body of a regular surface, an ear placed in the passage of these reflected waves will perceive a sound similar to the original sound, but which will seem to proceed from a body situated in a similar position and distance behind the plane of reflection, as the real sounding body is before it. This reflected sound is commonly called an echo, which, however, cannot take place at less than fifty-five feet; because it is necessary that the distance should be such, and the reverberated or reflected sound so long in arriving, that the ear may distinguish clearly between that and the original sound.

Reflected sound may be magnified by much the same contrivances as are used in optics respecting light: hence it follows, that sounds uttered in one focus of an elliptical cavity are heard much magnified in the other focus. The whispering-gallery at St. Paul's cathedral in London, is of this description; a whisper uttered at one side of the dome is reflected to the other, and may be very distinctly heard. The speaking and ear trumpets are constructed on this principle. The best form for these instruments is a hollow parabolic conoid, with a small orifice at the top or apex, to which the mouth is applied when the sound is to be magnified, or the ear when the hearing is to be facilitated.

The structure of the ear is one of the most complicated and difficult subjects of physiology; and the reader is, therefore, referred to that article for what concerns this branch of acoustics.

Sound, *musical.* Sounds of such qualities and dispositions as to produce that agreeable and appreciable effect upon the ear which we call melody, or harmony. We shall at present confine our observations to that affection of sound by which it becomes distinguished into acute and grave

This difference has hitherto appeared to have no other causes than the different velocities of the vibrations of the sounding bodies. In fact, the tone or pitch of a sound seems to have been discovered, by an abundance of experiments, to depend on the nature of those vibrations, whose difference we can conceive no otherwise than as having different velocities; and since it is proved, that all the vibrations of the same chord are performed in equal time; and that the tone of a sound, which continues for some time after the stroke, is the same from first to last; it follows, that the tone is necessarily connected with a certain quantity of time in making each vibration: and it is from this principle that all the phenomena of tune are deduced.

If the vibrations are isochronous, the sound is called musical; and is said to be acuter, or higher, than any other sound whose vibrations are slower and graver, or lower than any other sound whose vibrations are quicker.

From the same principle arise what we call concords, &c. which are resolvable into the frequent unions and coincidences of the vibrations of two sonorous bodies, and consequently of the undulations of the air which they occasion. On the contrary, the result of less frequent coincidences of those vibrations is what we call discord.

Another considerable distinction of musical sounds is, that by which they are denominated long and short; not with regard to the sonorous body's retaining a motion, once received, a longer or lesser time, but to the continuation of the impulse of the efficient cause on the sonorous body for a longer or shorter time; as in the notes of a violin, &c. which are made longer or shorter by strokes of different length or quickness.

This continuity is, properly, a succession of several sounds, or the effect of several distinct strokes, or repeated impulses, on the sonorous body, so quick that we may judge it one continued sound, especially if it is continued in the same degree of strength; and hence arises the doctrine of measure and time.

Sounds again are distinguished by musicians into simple and compound.

A simple sound is the single product of one voice, or one instrument.

A compound sound consists of the sounds of several distinct voices or instruments, all united in the same individual time and measure of duration, that is, all striking the ear together, whatever may be their other differences. But in this sense there is a twofold compound, natural and artificial.

The natural compound is that proceeding from the manifold reflections of the first sound from adjacent bodies, when the reflections are not so sudden as to occasion echoes, but are all given at the same moment, as well as in the same tone, or pitch, with the first note.

The artificial compound, which alone comes under the musician's province, is that mixture of several different sounds, which being produced by art, the ingredient sounds are separable, and distinguishable from one another. In this sense the distinct sounds of several voices or instruments, or several notes of the same instrument, are called simple sounds, in contradistinction to the compound ones, in which, to answer the purposes of music, the simples must have such an agreement in all relations, chiefly as to acuteness and gravity, as that the ear may receive the mixture with pleasure.

Sound, in geography, denotes in general any streight, or inlet, of the sea, between the two headlands.

Sound-board, in an organ, is a reservoir into which the wind, drawn in by the bellows, is conducted by a port-vent, and hence distributed into the pipes placed over holes in its upper part; this wind enters them by valves, which open by pressing upon the stops or keys; after drawing the registers, which prevent the air from entering any of the pipes, except those it is required in.

SOUNDING, in navigation, the act of trying the depth of the water, and the quality of the bottom, by a line and plummet, or other artifice.

At sea there are two plummets used for this purpose, both shaped like the frustum of a cone or pyramid. One of these is called the hand-lead, weighing about eight or nine pound; and the other the deep-sea lead, weighing from 25 to 30 pounds. The former is used in shallow waters, and the latter at a great distance from the shore. The line of the hand-lead is about 25 fathoms in length, and marked at every two or three fathoms, in this manner, viz. at two and three fathoms from the lead there are marks of black leather; at five fathoms a white rag, at seven a red rag, at ten and at thirteen black leather, at fifteen a white rag, and at seventeen a red one.

Sounding with the hand-lead, which the seamen call heaving the lead, is generally performed by a man who stands in the main-chains to windward. Having the line all ready to run out, without interruption, he holds it nearly at the distance of a fathom from the plummet: and having swung the latter backwards and forwards three or four times, in order to acquire the greater velocity, he swings it round his head, and thence as far forward as is necessary; so that, by the lead's sinking whilst the ship advances, the line may be almost perpendicular when it reaches the bottom. The person sounding then proclaims the depth of the water in a kind of song resembling the cries of hawkers in a city; thus, if the mark of 5 is close to the surface of the water, he calls, "by the mark five," and as there is no mark at 4, 6, 8, &c. he estimates those numbers, and calls, "by the dip four," &c. If he judges it to be a quarter or a half more than any particular, number he calls, "and a quarter five," "and a half four," &c. If he conceives the depth to be three quarters more than a particular number, he calls it a quarter less than the next; thus, at four fathoms $\frac{3}{4}$, he calls, "a quarter less 5," and so on.

The deep-sea lead-line is marked with two knots at 20 fathoms, three at 30, four at 40, &c. to the end. It is also marked with a single knot at the middle of each interval, as at 25, 35, 45 fathoms, &c. To use this lead more effectually at sea, or in deep water on the sea-coast, it is usual previously to bring-to the ship, in order to retard her course; the lead is then thrown as far as possible from the ship on the line of her drift, so that, as it sinks, the ship drives more perpendicularly over it. The pilot feeling the lead strike the bottom, readily discovers the depth of the water by the mark on the line nearest its surface. The bottom of the lead, which is a little hollowed there for the purpose, being also well rubbed over with tallow, retains the distinguishing marks of the bottom, as shells, ooze, gravel, &c. which naturally adhere to it.

The depth of the water, and the nature of the ground, which are called the soundings, are carefully marked in the log-book, as well to determine the distance of the place from the shore, as to correct the observations of former pilots.

SOUTHERNWOOD. See Artemisia.

SOW, in the iron-works, the name of the block or lump of metal they work at once in the iron-furnace. The size of these sows of iron is very different, even from the same workmen, and the same furnace. These furnaces having sand-stones for their hearths and sides up to the height of a yard, and the rest being made of brick, the hearth by the force of the fire is continually growing wider, so that if it at first contains as much metal as will make a sow of six or seven hundred weight, it will at last contain as much as will make a sow of 2000 weight.

SOWANS. See Starch.

SOWNE, a term used in the exchequer, where estreats that sowne not, are such as the sheriff by his care and diligence cannot levy, wherefore they are not regarded; and the estreats that sowne, are such as he may levy.

SPA. See Waters, *mineral*.

SPACE, in geometry, denotes the area of any figure, or that which fills the interval or distance between the lines that terminate it.

Space, in mechanics, the line a moveable body, considered as a point, is conceived to describe by its motion.

SPAN, a measure taken from the space between the thumb's end and the tip of the little finger, when both are stretched out. The span is estimated at 3 hand's-breadths, or 9 inches. See Measure.

SPANIEL. See Canis.

SPAR. See Fluat *of lime*.

Spar, in mineralogy, a name given to those earths which break easily into rhomboidal, cubical, or laminated fragments with polished surfaces. As the term spar is thus applied to stones of different kinds, without any regard to the ingredients of which they are composed, some additional term must be used to express the constituent parts as well as the figure; for instance, calcareous spar, gypseous spar, &c. The spars found in Britain and Ireland are of four different species, opaque, refracting, diaphanous, and stalactitical. 1. The opaque spar is rhomboidal, hexangular, and triangular, of various colours, and is found in mines in Wales, Derbyshire, &c. and at Ovens near Cork. 2. The refracting spar is rhomboidal, shows objects seen through it double, and sometimes 8, 12, or 16 images at once. It is frequent in the lead-mines of Derbyshire, Yorkshire, &c. 3. Diaphanous spar is rhomboidal, triangular, hexangular, pyramidal or columnar; and is found in mines, quarries, and caverns, in many different places. 4. Stalactitical spar, icicle, or drop-stone, is formed by the running or dropping of water, containing a large proportion of calcareous earth. It is opaque, generally laminated, but from accidental circumstances assumes various forms. It occurs at Knaresborough in Yorkshire, and at Ovens near Cork.

A new species of spar has lately been found in the East Indies, which, from its extreme hardness, approaching to that of a diamond, is called adamantine spar. It was discovered by Dr. Black of Edinburgh to be a distinct species. Happening one day to visit a lapidary, it was shown to him among other specimens as a stone that was used in the East Indies for polishing gems, and grinding other hard substances. Dr. Black immediately singled out a specimen, which he sent to Mr. Greville, who requested M. Klaproth to analyse it.

There are two varieties of this spar; one of them comes from China, and crystallizes in hexagonal prisms without pyramids, the length of the sides varying from six to twelve lines; their breadth being about nine, of a grey colour with different shades. Though the entire pieces are opaque, the thin laminæ are transparent, and when broken, its surface appears slightly striated. Its crystals are covered with a very fine and strongly-adhering crust, composed of scales of silvery mica, mixed with particles of red feld-spar. Sometimes the surface has martial pyrites or yellow sulphuret of iron adhering to it. Its hardness is so great, that it not only cuts glass as easily as the diamond, but even scratches rock crystal and other very hard stones. Its specific gravity is to that of water as 3710 to 1000. Sometimes it contains crystallized grains of magnetic oxyd of iron, which may be separated from the stone when pulverized by means of the loadstone.

The other kind found in Hindostan is of a white colour, and of a more laminated texture than the former: the grains of iron contained in it are likewise of a smaller size than those of the former; they are not diffused through the substance, but only adhere to its surface. This spar is exceedingly difficult to analyse.

SPARGANIUM, *bur-reed*, a genus of plants belonging to the class of monœcia, and to the order of triandria, and in the natural system ranged under the 3d order, calamariæ. The amentum of the male flower is roundish, the calyx is triphyllous, and there is no corolla. The amentum of the female flower resembles that of the male. The stigma is bifid; the fruit is a dry berry containing one seed. There are three species, all of them natives of Great Britain and Ireland, and growing in pools and lakes.

SPARMANNIA, a genus of plants belonging to the class of polyandria, and to the order of monogynia. The corolla consists of four petals, and is bent back; the nectaria are numerous, and swell a little; the calyx is quadriphyllous; the capsule is angulated, quinquelocular and echinated. There is only one species, the africana, a shrub of the Cape.

SPARROW. See Fringilla.

Sparrow-hawk. See Falco.

SPARTIUM, *broom*, a genus of plants belonging to the class of diadelphia, and order of decandria, and in the natural system arranged under the 32d order, papilionaceæ. The stigma is longitudinal and woolly above, the filaments adhere to the germen. The calyx is produced downwards. There are 27 species. All these, except the scoparium, are exotics, chiefly from Spain, Portugal, Italy, &c. The scoparium, or common broom, is used for a variety of purposes. It has been a great benefit sometimes in dropsical complaints. The manner in which Dr. Cullen administered it was this: he ordered half an ounce of fresh broom-tops to be boiled in a pound of water till one-half of the water was evaporated. He then gave two table-spoonfuls of the decoction every hour till it operated both by stool and urine. By repeating these doses every day, or every second day, he says some dropsies have been cured. Dr. Mead relates, that a dropsical patient, who had taken the usual remedies, and been tapped three times without effect, was cured by taking half a pint of the decoction of queen-broom tops, with a spoonful of whole mustard-seed, every morning and evening. "An infusion of the seeds drunk freely (says Mr. Withering) has been known to produce similar happy effects; but whoever expects these effects to follow in every dropsical case will be greatly deceived. I knew them succeed in one case that was truly deplorable; but out of a great number of cases in which the medicine had a fair trial, this proved a single instance."

The flower-buds are in some countries pickled, and eaten as capers; and the seeds have been used as a bad substitute for coffee. The branches are used for making besoms, and tanning leather. They are also used instead of thatch to cover houses. The old wood furnishes the cabinet-maker with beautiful materials for veneering. The tender branches are in some places mixed with hops for brewing, and the macerated bark may be manufactured into cloth.

SPARGELSTEIN, a mineral found in Spain, where it forms whole mountains, in different parts of Germany, and in Cornwall. It is sometime amorphous, and sometimes crystallized. The primitive form of its crystals is a regular six-sided prism. Its integrant molecule is a regular triangular prism, whose height is to a side of its base, as 1 to $\sqrt{2}$. Sometimes the edges of the primitive hexagonal prism are wanting, and small faces in their place; sometimes there are small faces instead of the edges, which terminate the prism; sometimes these two varieties are united.

SPARUS, a genus of fishes of the order thoracici: the generic character is, the teeth strong; front teeth in some species disposed in a single row, in others in a double, triple, or quadruple row: grinders (in most species) convex, smooth, and disposed in ranges, forming a kind of pavement in the mouth: lips thick; gill-covers unarmed, smooth, scaly. The genus sparus is extremely numerous, there being more than 40 species, and as the greater number are exotic, very little is known of their history; a general survey is therefore all that can be expected; it may be observed that they are much allied to the labri, and that the distinction between these two genera is not, in all cases, so clear as might be wished: in the Systema Naturæ of Linnæus an evident confusion takes place with respect to the characters of both.

Sparus aurata. Gilt-head sparus. General length about fifteen inches, but occasionally found of far larger size; body broad and thin, the back rising into a carina: native of the Mediterranean, Atlantic, and Indian seas, and held in considerable esteem as a food; much admired by the antient Greeks and Romans, and by the former nation consecrated to Venus.

SPATHELIA, a genus of plants belonging to the class of pentandria, and to the order of trigynia. The calyx is pentaphyllous; the petals are five; the capsule is three-edged and trilocular; the seeds solitary. There is only one species, the simplex, which is a native of Jamaica, and was introduced into the botanic gardens of this country in 1778 by Dr. Wright, late of Jamaica.

SPASM. See Medicine.

SPATULA, an instrument used by surgeons and apothecaries for spreading plasters, &c.

SPECIES, in algebra, the characters or symbols made use of to represent quantities.

SPECIFIC, in medicine, a remedy whose virtue and effect is peculiarly adapted to some certain disease, is adequate thereto, and exerts its whole force immediately thereon.

Specific, in philosophy, that which is peculiar to any thing, and distinguishes it from all others.

SPECIOUS ARITHMETIC, the same with algebra.

SPECULARIS LAPIS, in natural history, a genus of talcs, composed of large plates visibly separate, and of extreme thinness; and each fissile again separated into a number of plates still finer. (See Talc.) Of this genus there are three species: 1. The white shining specularis, with large and broad leaves, commonly called isinglass and Muscovy glass; its lamellæ, or leaves, are extremely thin, elastic, and transparent; it makes sometimes not the least effervescence with aquafortis, and is not easily calcined in the fire. It is imported in great quantities; the miniature-painters cover their pictures with it; the lantern-makers use it instead of horn; and minute objects are usually preserved between two plates of it, for examination by the microscope. 2. The bright-brown specularis, with broad leaves; a very valuable species, though inferior to the former. 3. The purple bright specularis, with broad leaves, the most elegant of all the talcs, and as beautifully transparent as the first kind.

SPECULUM, a *looking-glass* or *mirror*, capable of reflecting the rays of the sun, &c. See Optics: see also Foliating *of looking-glasses*, vol. i. p. 758.

Speculum, in surgery, an instrument for dilating a wound, or the like, in order to examine it attentively.

Speculum for reflecting telescopes, is made of a kind of white copper consisting of 32 parts of fine red copper, one of brass, fifteen of grain-tin, and three of white arsenic. The process given by the late J. Edwards, who was rewarded by the board of longitude for disclosing it to the public, was published in the Nautical Almanack for 1787, and is as follows: Melt the copper in a large crucible, employing some black flux, composed of two parts of tartar and one of nitre; when melted, add to it the brass and the silver. Let the pure tin be melted into another crucible, also with some black flux. Take them both from the fire, and pour the melted tin into the fused mass in the large crucible. Stir the whole well with a dry spatula of birch; and pour off the fused metal immediately into a large quantity of cold water. The sudden chill of the water will cause the fluid metal to divide into an infinite number of small particles, which will cool instantly. 2. If the copper is completely saturated, the fracture of one piece of this mixed metal will appear bright, and of a glossy look, resembling the face of pure quicksilver. But if it is a brown reddish-colour, it wants a little more tin. To ascertain the required proportion, melt a small quantity, known by weight, of the mixed metal, with a known very small part of tin; and, if necessary, repeat the trial with different doses, till the fracture of the new mixture looks as already described. Having now ascertained the necessary addition of tin that is required, proceed to the last melting of the whole metal, together with the additional proportional dose of tin; fuse the whole, observing the same cautions as before, and you will find that the mixture will melt with a much less heat than that for the first fusion. Have ready as many ounces of white arsenic in coarse powder as there are pounds in the weight of metal; wrap up the arsenic in a small paper, and put it, with a pair of tongs, into the crucible; stir it well with the spatula, retaining the breath to avoid the arsenical fumes or vapours (which however are not found to be hurtful to the lungs) till they disappear; take the crucible off the fire, clear away the dross from the top of the metal; pour in about one ounce of powdered rosin, with as much nitre, in order to give the metal a clean surface, and pour out the metal into the moulded flasks. 3. The speculum should be moulded with the concave surface downwards, and many small holes should be made through the sand upwards, to discharge the air. The moulding-sand from Highgate near London, used by the founders, is as good as any for casting these metallic mirrors. The cast metal should be taken out from the sand of the flasks whilst it is hot, or else it may happen to crack if left to cool within.

SPEEDWELL. See Veronica.

SPELTER. See Zinc.

SPENT, in the sea-language, signifies the same as broken.

SPERGULA, *spurrey*, a genus of plants belonging to the class of decandria, and the order of pentagynia, and in the natural system arranged under the 22nd order, caryophyllеæ. The calyx is pentaphyllous; the petals five, and undivided; the capsule oval, unilocular, and containing five valves. There are seven species, five of which are British: 1. The arvensis, corn-spurrey, has linear furrowed leaves, from eight to twenty in a whorl. The flowers are small, white, and terminal. It is frequent in corn-fields. In Holland it is cultivated as food for cattle, and has the advantage of growing on the very poorest soils, but does not afford a great deal of food. Poultry are fond of the seeds; and the inhabitants of Finland and Norway make bread of them when their crops of corn fail. Horses, sheep, goats, and swine, eat it. Cows refuse it. 2. The nodosa, knotted spurrey. 3. Pentandra, small spurrey. 4. Laricina, larch-leaved spurrey. 5. Saginoides, pearlwort spurrey.

SPERMACETI. This peculiar oily substance is found in the cranium of the physeter mocrocephalus, or spermaceti-whale. It is obtained also from some other species. At first it is mixed with some liquid oil, which is separated by means of a woollen bag. The last portions are removed by an alkaline ley, and the spermaceti is afterwards purified by fusion. Thus obtained it is a beautiful white substance, usually in small scales, very brittle, has scarcely any taste, and but little smell. It is distinguished from all other fatty bodies by the crystalline appearance which it always assumes. It melts, according to the experiments of Bostock, at the temperature of 112°. When sufficiently heated it may be distilled over without much alteration; but when distilled repeatedly, it loses its solid form, and becomes a liquid oil. It is soluble in boiling alcohol, but separates again as the solution cools. About 150 parts of alcohol are necessary to dissolve it. Ether dissolves it cold, and very rapidly when hot: on cooling it concretes into a solid mass. It dissolves also in hot oil of turpentine, but precipitates again as the liquor cools.

The acids have hardly any action upon it, but it unites with the pure alkalies. With hot ammonia it forms an emulsion which is not decomposed by cooling nor by water. It dissolves sulphur, and is dissolved by the fixed oils.

SPERMACOCE, *button-wood*, a genus of plants belonging to the class of tetrandria, and order of monogynia, and in the natural system arranged under the 47th order, stellatæ. The corolla is monopetalous and funnel-shaped, and there are two bidentate seeds. The species are 20, all stove plants from warm climates.

SPHACELUS. See SURGERY.

SPHÆRANTHUS, a genus of plants belonging to the class of syngenesia, and to the order of polygamia segregata; and in the natural system arranged under the 49th order, compositæ. Each partial calyx contains eight florets; the florets are tubulated, the female being scarcely distinguishable. The receptacle is scaly; and there is no pappus. The species are four, the indicus, the africanus, the chinensis, and another.

SPHÆRIA, a genus of the class and order cryptogamia fungi. The fructifications are mostly spherical, opening at the top; while young filled with jelly, when old with blackish powder. They grow on the bark or wood of other plants. There are 29 species.

SPHÆROCARPUS, a genus of the cryptogamia class of plants, and order algæ, consisting of foliaceous matter, expanded on the ground, and producing very large and obvious fructifications. Dr. Hill thinks it probable, that the male flowers are produced on separate plants from the female, and have not been discovered to belong to the same species: no male parts of fructification are described to us; the female parts consist of a tubulated and inflated vagina, within which is contained a large globular capsule, containing a great number of small loose seeds.

SPHAGNUM, *bog-moss*, a genus of plants belonging to the class of cryptogamia and order of musci. The antheræ are globose; the mouth entire, and closed by an operculum; the calyptra is wanting. There are three species, the palustre, alpinum, and arboreum. 1. The palustre, common bog-moss, grows on our bogs in wide patches, so as frequently to cover a large portion of their surface. The stalks are from two inches to two feet long, irregularly surrounded with numerous, conical, pendant branches, and terminated with a rotaceous cluster of erect short ones. It is generally believed, that the roots and decayed stalks of this moss constitute a principal part of that useful bituminous substance called peat, which is the chief fuel of the northern regions. The Lapland matrons are well acquainted with this moss. They dry and lay it in their cradle, to supply the place of bed, bolster, and every covering; and, being changed night and morning, it keeps the infant remarkably clean, dry, and warm. It is sufficiently soft of itself; but the tender mother, not satisfied with this, frequently covers the moss with the downy hairs of the rein-deer; and by that means makes a most delicate nest for the young babe. 2. The alpinum, green bog-moss. Its branches are subulate and erect; the antheræ are oval. It grows in mountain bogs in South Britain. 3. The arboreum, creeping bog-moss, is branched; the antheræ are numerous, sessile, hairy, and grow along the branches chiefly on one side. It is found on the trunks of trees.

SPHENOIDAL SUTURE. See ANATOMY.

SPHENOIDES. See ANATOMY.

SPHERE, is a solid contained under one uniform round surface, such as would be formed by the revolution of a circle about a diameter thereof as an axis. See GEOMETRY.

SPHERE, *properties of the*, are as follow:

1. A sphere may be considered as made up of an infinite number of pyramids, whose common altitude is equal to the radius of the sphere, and all their bases form the surface of the sphere. And therefore the solid content of the sphere is equal to that of a pyramid whose altitude is the radius, and its base is equal to the surface of the sphere, that is, the solid content is equal to $\frac{1}{3}$ of the product of its radius and surface.

2. A sphere is equal to $\frac{2}{3}$ of its circumscribing cylinder, or of the cylinder of the same height and diameter, and therefore equal to the cube of the diameter multiplied by .5236, or $\frac{2}{3}$ of .7854; or equal to double a cone of the same base and height. Hence all different spheres are to one another as the cubes of their diameters, and their surfaces as the squares of the same diameters.

3. The surface or superficies of any sphere, is equal to four times the area of its great circle, or of a circle of the same diameter as the sphere. Or,

4. The surface of the whole sphere is equal to the area of a circle whose radius is equal to the diameter of the sphere. And, in like manner, the curve surface of any segment, whether greater or less than a hemisphere, is equal to a circle whose radius is the chord line drawn from the vertex of the segment to the circumference of its base, or the chord of half its arc.

5. The curve surface of any segment or zone of a sphere, is also equal to the curve surface of a cylinder of the same height with that portion, and of the same diameter with the sphere. Also the surface of the whole sphere, or of a hemisphere, is equal to the curve surface of its circumscribing cylinder. And the curve surfaces of their corresponding parts are equal, that are contained between any two places parallel to the base. And consequently the surface of any segment or zone of a sphere, is as its height or altitude.

Most of these properties are contained in Archimedes's treatise on the sphere and cylinder. And many other rules for the surfaces and solidities of spheres, their segments, zones, frustums, &c. may be seen in Bonnycastle's Mensuration.

Hence, if d denotes the diameter or axis of a sphere, s its curve surface, c its solid content, and $a = .7854$ the area of a circle whose diam. is 1; then we shall, from the foregoing properties, have these following general values or equations, viz.

$$s = 4ad^2 = \frac{6c}{d} = 6\sqrt[3]{\tfrac{2}{3}ac^2}.$$

$$s = \tfrac{1}{6}ds = \tfrac{2}{3}ad^3 = \tfrac{1}{12}\sqrt{\frac{s^3}{a}}.$$

$$d = \frac{6c}{s} = \sqrt{\frac{s}{4a}} = \sqrt[3]{\frac{3c}{2a}}.$$

SPHERE, in astronomy, that concave orb, or expanse, which invests our globe, and in which the heavenly bodies appear to be fixed, and at an equal distance from the eye.

SPHERE, *armillary*. See ARMILLARY SPHERE.

SPHERICS, the doctrine of the sphere, particularly of the several circles described on its surface, with the method of projecting the same on a plane. See PROJECTION *of the sphere*.

A circle of the sphere is that which is made by a plane cutting it. If the plane passes through the centre, it is a great circle: if not, it is a little circle.

The pole of a circle, is a point on the surface of the sphere, equidistant from every point of the circumference of the circle. Hence every circle has two poles, which are diametrically opposite to each other; and all circles that are parallel to each other have the same poles.

Properties of the circles of the sphere. 1. If a sphere is cut in any manner by a plane, the section will be a circle; and a great circle when the section passes through the centre, otherwise it is a little circle. Hence all great circles are equal to each other: and the line of section of two great circles of the sphere, is a diameter of the sphere: and therefore two great circles intersect each other in points diametrically opposite; and make equal angles at those points; and divide each other into two equal parts; also any great circle divides the whole sphere into two equal parts.

2. If a great circle is perpendicular to any other circle, it passes through its poles. And if a great circle passes through the pole of any other circle, it cuts it at right angles, and into two equal parts.

3. The distance between the poles of two circles is equal to the angle of their inclination.

4. Two great circles passing through the poles of another great circle, cut all the parallels to this latter into similar arcs. Hence, an angle made by two great circles of the sphere, is equal to the angle of inclination of the planes of these great circles. And hence also the lengths of those parallels are to one another as the sines of their distances from their common pole, or as the cosines of their distances from their parallel great circle. Consequently, as radius is to the cosine of the latitude of any point on the globe, so is the length of a degree at the equator, to the length of a degree in that latitude.

5. If a great circle passes through the poles of another, this latter also passes through the poles of the former; and the two cut each other perpendicularly.

6. If two or more great circles intersect each other in the poles of another great circle; this latter will pass through the poles of all the former.

7. All circles of the sphere that are equally distant from the centre, are equal; and the farther they are distant from the centre, the less they are.

8. The shortest distance on the surface of a sphere, between any two points on that surface, is the arc of a great circle passing through those points. And the smaller the circle is that passes through the same points, the longer is the arc of distance between them. Hence the proper measure, or distance, of two places on the surface of the globe, is an arc of a great circle intercepted between the same. See Theodosius, and other writers on spherics.

SPHEROID, a solid body approaching to the figure of a sphere, though not exactly round, but having one of its diameters longer than the other.

This solid is usually considered as generated by the rotation of an oval plane figure about one of its axes. If that is the longer or transverse axis, the solid so generated is called an oblong spheroid, and sometimes prolate, which resembles an egg, or a lemon; but if the oval revolves about its shorter axis, the solid will be an oblate spheroid, which resembles an orange, and in this shape also is the figure of the earth, and of the other planets.

The axis about which the oval revolves, is called the fixed axis, and the other is the revolving axis, whichever of them happens to be the longer.

When the revolving oval is a perfect ellipse, the solid generated by the revolution is properly called an ellipsoid; as distinguished from the spheroid, which is generated from the revolution of any oval whatever, whether it is an ellipse or not. But generally speaking, in common acceptation, the term spheroid is used for an ellipsoid; and therefore, in what follows, they are considered as one and the same thing.

Any section of a spheroid by a plane, is an ellipse (except the sections perpendicular to the fixed axis, which are circles); and all parallel sections are similar ellipses, or having their transverse and conjugate axes in the same constant ratio; and the sections parallel to the fixed axis are similar to the ellipse from which the solid was generated.

For the surface of the spheroid, whether it is oblong or oblate:

Let f denote the fixed axis,
r the revolving axis,
$a = .7854$, and $q = \frac{ff \backsim rr}{ff}$; then will

the surface s be expressed by the following series, using the upper signs for the oblong spheroid, and the under signs for the oblate one; viz.

$$s = 4arf \times (1 \mp \frac{1}{2.3} q - \frac{1}{2.4.5} q^2 \mp \frac{3}{2.4.6.7} q^3$$

&c.; where the signs of the terms, after the first, are all negative for the oblong spheroid, but alternately positive and negative for the oblate one.

Hence, because the actor $4\,arf$ is equal to 4 times the area of the generating ellipse, it appears that the surface of the oblong spheroid is less than 4 times the generating ellipse: but the surface of the oblate spheroid is greater than 4 times the same; while the surface of the sphere falls in between the two, being just equal to 4 times its generating circle.

Huygens has given two elegant constructions for describing a circle equal to the superficies of an oblong and an ovate spheroid, which he says he found out towards the latter end of the year 1657.

Of the solidity of a spheroid. Every spheroid, whether oblong or oblate, is, like a sphere, exactly equal to two-thirds of its circumscribing cylinder. So that, if f denotes the fixed axis, r the revolving axis, and $a =$ 7854; then $\frac{2}{3}\,afr^2$ denotes the solid content of either spheroid. Or, which comes to the same thing, if t denotes the transverse, and c the conjugate axis of the generating ellipse;

then $\frac{2}{3}ac^2t$ is the content of the oblong spheroid,

and $\frac{2}{3}ac^2t$ is the content of the oblate spheroid.

Consequently, the proportion of the former solid to the latter, is as c to t, or as the less axis to the greater.

Farther, if about the two axes of an ellipse are generated two spheres and two spheroids, the four solids will be continued proportionals, and the common ratio will be that of the two axes of the ellipse; that is, as the greater sphere, or the sphere upon the greater axis, is to the oblate spheroid, so is the oblate spheroid to the oblong spheroid, and so is the oblong spheroid to the less sphere, and so is the transverse axis to the conjugate.

SPHEROID, *universal*, a name given to the solid generated by the rotation of an ellipse about some other diameter, which is neither the transverse nor conjugate axis.

SPHEX, a genus of insects of the order hymenoptera. The generic character is, mouth with jaws, without tongue; antennæ of ten joints; wings flat-incumbent (not pleated) in each sex; sting concealed. As the insects of the genus ichneumon deposit their eggs in the bodies of other living insects, so those of the genus sphex deposit theirs in dead ones, in order that the young larvæ, when hatched, may find their proper food. 1. Thus the sphex figulus of Linnæus, having found some convenient cavity for the purpose, seizes on a spider, and having killed it, deposits it at the bottom: then laying her egg in it, she closes up the orifice of the cavity with clay: the larva, which resembles the maggot of a bee, having devoured the spider, spins itself up in a dusky silken web, and changes into a chrysalis, out of which, within a certain number of days, proceeds the complete insect, which is of a black colour, with a slightly foot-stalked abdomen, the edges of the several segments being of a brighter appearance than the rest of the body. It should be added, that the female of this species prepares several separate holes or nests as abovementioned, in each of which she places a dead insect and an egg: each cell costing her the labour of about two days.

2. The sphex viatica of Linnæus, which is of a black colour and slightly hairy, with brown wings, and the fore part of the abdomen ferruginous with black bands, seizes caterpillars in a similar manner, burying one in every cell, in which she deposits an egg, and then closes up the cell.

3. Sphex sabulosa Lin. is a black and hairy species, with the second and third joints of the abdomen ferruginous. It inhabits sandy and gravelly places, in which the female digs holes with her fore-feet, working in the manner of a dog, in order to form the cavity, in which she places either a spider or a caterpillar; after which she closes up the cavity, having first laid her egg in the dead insect. Linnæus, in his description of this insect, contradicts the generic character, since he observes that it has a retractile snout containing the tongue.

Many of the extra-European spheges are insects of a very considerable size. The whole genus is very much allied to those of vespa and apis. There are 38 species. See Plate Nat. Hist. fig. 369.

SPHINCTER. See ANATOMY.

SPHINX, the hawk moth, a genus of insects of the order lepidoptera. The generic character is, antennæ thickest in the middle, subprismatic, and attenuated at each extremity; wings deflected; flight strong, and commonly in the evening or morning. The insects of this genus have in general a large thorax and thick body, commonly tapering towards the extremity. The name sphinx is applied to the genus on account of the posture assumed by the larvæ of several of the larger species, which are often seen in an attitude much resembling that of the Egyptian sphinx, viz. with the fore parts elevated, and the rest of the body applied flat to the surface.

1. One of the most elegant insects of this genus is the sphinx ligustri, or privet hawkmoth. It is a large insect, measuring nearly four inches and a half from wing's end to wing's end: the upper wings of a brown colour, most elegantly varied or shaded with deeper and lighter streaks and patches; the under wings

and body are of a fine rose-colour, barred with transverse black stripes. The caterpillar, which is very large, is smooth, and of a fine green, with seven oblique purple and white stripes along each side: at the extremity of the body, or top of the last joint, is a horn or process pointing backwards. This beautiful caterpillar is often found in the months of July and August feeding on the privet, the lilac, the poplar, and some other trees, and generally changes to a chrysalis in August or September, retiring for that purpose to a considerable depth beneath the surface of the ground, and, after casting its skin, continuing during the whole winter in a dormant state, the sphinx emerging from it in the succeeding June.

2. The sphinx ocellata is perhaps still more beautiful: it is rather a smaller insect than the preceding, and has the upper wings and body brown, the former finely clouded with different shades, while the lower wings are of a bright rose-colour, each marked with a large ocellated black spot with a blue interior circle and a black centre. This insect proceeds from a green caterpillar of a rough or shagreen-like surface, marked on each side by seven oblique yellowish-white streaks, and furnished, like the preceding, with a horn at the tail. It is principally found on the willow; retires under ground, in order to undergo its change into the chrysalis state, in the month of August or September; and in the following June appears the complete insect.

3. But the largest and most remarkable, if not the most beautiful European insect of this genus, is the sphinx atropos of Linnæus, see Plate Nat. Hist. fig. 370, which very considerably exceeds in size both the species already mentioned. The upper wings are of a fine dark-grey colour, with a few slight variegations of dull orange and white: the under wings are of a bright orange-colour, marked by a hair of transverse black bands; the body is also orange-coloured, with the sides marked by black bars, while along the top of the back, from the thorax to the tail, runs a broad blue-grey stripe: on the top of the thorax is a very large patch of a most singular appearance, exactly representing the usual figure of a skull or death's-head, and of a pale grey, varied with dull ochre-colour and black. When in the least disturbed or irritated, this insect emits a stridulous sound, something like the squeaking of a bat or mouse; and from this circumstance, as well as from the mark above-mentioned on the thorax, is held in much dread by the vulgar in several parts of Europe, its appearance being regarded as a kind of ill omen, or harbinger of approaching fate. We are informed by the celebrated Reaumur, that the members of a female convent in France were thrown into great consternation at the appearance of one of these insects, which happened to fly in during the evening at one of the windows of the dormitory. The caterpillar from which this curious sphinx proceeds is in the highest degree beautiful, and far surpasses in size every other European insect of the kind; measuring sometimes near five inches in length, and being of a very considerable thickness: its colour is a bright yellow, the sides marked by a row of seven most elegant broad stripes or bands, of a mixed violet and sky-blue colour. This caterpillar is principally found on the potatoe and the jessamine, those plants being its favourite food. It usually changes into a chrysalis in the month of September, retiring for that purpose pretty deep under the surface of the earth; the complete insect emerging in the following June or July. The sphinx atropos is generally considered as a very rare insect; and as the caterpillar feeds chiefly by night, concealing itself during the day under leaves, &c. it is not often detected.

We shall not conclude the survey of the genus sphinx without observing, that it contains some species of a smaller size, and of a somewhat different habit from the kinds above described. Among these is the beautiful sphinx fillipendulæ, or dropwort sphinx, common in meadows towards the decline of summer, and which is distinguished by having the upper wings of an oblong-oval shape and of a dark shining green colour, with blood-red spots, and the lower wings red with a dark green edging: the caterpillars of a pale yellow, with rows of squarish black spots, and often seen feeding on various meadow-plants and grasses: it does not undergo its change under ground, but encloses itself in an oval shining yellow web of silk, attached to the stem of some grass, &c. In this it changes into a chrysalis, out of which in about the space of three weeks emerges the complete insect. See Plate Nat. Hist. fig. 371.

Others of the smaller sphinges are remarkable for having the wings in a considerable degree transparent: of this kind is the sphinx apiformis, which is of an aspect at first sight more resembling that of a wasp or hornet than of a sphinx, the wings being transparent with merely a slight edging of brown, and the thorax and abdomen varied with black and yellow. The caterpillar inhabits the hollows of poplar, sallow, willow, and lime trees, feeding on the substance of the bark; changing to a chrysalis in April, and the fly appearing in the month of June.

Sphinx crabroniformis is so much like the former as scarcely to be distinguished from it, and inhabits the hollows of the sallow and other willows, feeding on the wood: it changes to a chrysalis in May, and the fly appears in July.

SPICA VIRGINIS, a star of the first magnitude, in the constellation Virgo.

SPIDER. See ARANEA.

SPIDER'S WEB. See SILK.

SPIDER'S VENOM. See POISONS.

SPIELMANNIA, a genus of the didynamia angiospermia class and order. The calyx is five-cleft; corolla bearded at the throat, with five-cleft border; drupe with a two-celled, two-seeded nut. There is one species, a shrub of the Cape.

SPIES, in war, are persons employed to give intelligence of what the enemy is doing. By making a proper use of the necessary creatures, the most secret designs of an enemy may be discovered, the positions his army are to take, the stations of his fleets, and even the manner in which the former is to be secured by masked batteries, or the latter be kept firm with chain-moorings, as was the case off Boulogne in 1800. If they are apprehended, they immediately suffer death.

SPIGELIA, *worm grass*, a genus of plants belonging to the class of pentandria, and order of monogynia; and in the natural system arranged under the 47th order, stellatæ. The corolla is funnel-shaped; the capsule is didymous, bilocular, and polyspermous. There are two species, the anthelmia and marilandica. 1. The anthelmia, see Plate Nat. Hist., fig. 372, has an herbaceous stem, and its highest leaves are fourfold. This plant is generally found in low dry lands, after they have been turned up some months, and after great rains; its taste is herbaceous, and somewhat clammy; its growth is soft and sudden; its stalk hollow, smooth, and roundish. Its medical qualities are highly spoken of by Dr. Browne. 2. The marilandica, perennial worm-grass, or Indian pink. Its stem is four-cornered; all the leaves opposite. Dr. Garden gave it in what he calls continued or remitting low worm-fevers, and found its efficacy promoted by the addition of rad. serpentar. virg.

SPIKING *up the ordnance*, a sea-phrase, used for fastening a quoin with spikes to the deck close to the breech of the carriages of great guns, that they may keep close and firm to the ship's sides, and not get loose when the ship rolls, and by that means endanger the breaking out of a butt-head of a plank.

SPILANTHUS, a genus of plants belonging to the class of syngenesia, and to the order of polygamia æqualis. The common calyx is erect; the leaflets numerous, subequal, and oblong, the two exterior being longer than the rest. The calyx is almost equal; down two-toothed, rectangular, conical, chaffy. There are nine species, annuals of hot climates.

SPINACIA, *spinage*, a genus of plants belonging to the class of diœcia, and to the order of pentandria; and in the natural system arranged under the 12th order, holoraceæ. The male calyx is quinquepartite; there is no corolla: the female calyx is quadrifid; no corolla; there are four styles, and one seed within the indurated calyx. There are only two species, the oleracea and fera. 1. The oleracea, common spinage, has sessile fruits and sagittated leaves. It has been cultivated in Britain since 1568, but it is not known from what country it was originally brought. When intended for winter use, it should be sown on an open spot of ground in the latter end of July; observing to do it, if possible, when the weather is rainy. The way of gathering it to advantage is only to take off the longest leaves, leaving those in the centre to grow bigger; and at this rate a bed of spinage will furnish the table for a whole winter, till the spinage sown in spring is become fit for use, which is commonly in April. 2. The fera, wild spinage, produces its fruit on footstalks.

SPINÆ. See BOTANY.

SPINALIS. See ANATOMY.

SPINDLE, in the sea language, is the smallest part of a ship's capstan, which is betwixt the two decks. The spindle of the jeer-capstan has whelps to heave the viol. The axis of the wheel of a watch or clock is also called the spindle. Among miners, the spindle is a piece of wood fastened into either stow-blade.

SPINDLE-SHELL. See BUCCINUM.

SPINE, *spina dorsi*. See ANATOMY.

SPINEL. This stone, which comes from the island of Ceylon, is usually crystallized. The form of its integrant particles is the tetrahedron. The primitive form of its crystals is a regular octahedron, composed of two four-sided pyramids applied base to base, each of the sides of which is an equilateral triangle. In some cases two opposite sides of the pyramids are broader than the other two; and sometimes the edges of the octahedron are wanting, and narrow faces in their place. For figures and descriptions of these, and other varieties of these crystals, the reader is referred to Romé de Lisle and the abbé Estner. It occurs also in tetrahedrons, in rhomboids whose faces have angles of 120° and 60°, in rhomboidal dodecahedrons, and in four-sided prisms terminated by four-sided pyramids.

The texture of the spinel is foliated. Fracture conchoidal. Its lustre is 3. Transparency 2 to 4. It causes a single refraction. Hardness 13. Specific gravity 3.570 to 3.625. Colour red, of various shades; sometimes also blue, green, and yellow. The constituents of the spinel are, according to

Vauquelin,		Klaproth,	
86.00	alumina	76	alumina
8.50	magnesia	16	silica
5.25	chromic acid	8	magnesia
		1.5	oxide of iron
99.76		101.5	

SPINET, or Spinnet, a musical instrument ranked in the second or third place among harmonious instruments. The harpsichord is a kind of spinet, only with another disposition of the keys.

SPINIFEX, a genus of plants belonging to the class of polygamia and order of dioecia. The hermaphrodite flowers have a calyx with bivalved biflorous glumes, the valvelets being parallel to the rachis; the corolla is bivalved and awnless; there are three stamina and two styles. In the male flowers the calyx is common with the hermaphrodite; the corolla and stamina are similar. There is only one species, the squarrosus, a grass of the East Indies.

SPINNING, the act of reducing silk, flax, hemp, hair, wool, or other matter, into thread. Spinning is either performed on the wheel, or with a distaff and spindle, or with other machines proper for the several kinds of working. Hemp, flax, nettle-thread, and other like vegetable matters, are to be wetted in spinning: silks, wools, &c. are spun dry, at least they do not stand in need of water: there is, however, a way of spinning or reeling silk as it comes off the cases or balls, where hot, and even boiling, water is to be used. The vast variety, and importance of these branches of our manufactures, which are produced from cotton, wool, and flax, spun into yarn, together with the cheapness of provisions, and the low price of labour, in many foreign countries, which are the rivals of our trade, have occasioned many attempts at home to render spinning more easy, cheap, and expeditious. Mr. Arkwright has carried the invention to a high degree of perfection. He not only contrived methods for spinning cotton, but obtained a patent for making cotton, flax, and wool, into yarn.

SPINSTER, in law, an addition usually given to all unmarried women from a viscount's daughter downwards.

SPIO, a genus of vermes of the order mollusca. The generic character is, body projecting from a tube, jointed, and furnished with dorsal fibres; peduncles or feet rough with bristles, and placed towards the back; feelers two, long, simple; eyes two, oblong. There are two species, viz. 1. The seticornis, which inhabits the ocean where there is a clayey bottom, is about three inches long: the tube is composed of agglutinated particles of earth, thin, erect, and thrice as long as the body. From this the animal projects its capillary white feelers, in search of food, which consists of marine worms. 2. Filicornis, that inhabits the Greenland seas: tube fragile, erect, greenish, from which it projects its feelers in search of planariæ and other small marine worms.

SPIRACULA, in entomology, holes or pores on each side of every segment of the abdomen, through which insects breathe.

SPIRÆA, a genus of plants belonging to the class of icosandria, and to the order of pentagynia; and in the natural system arranged under the 26th order, pomaceæ. The calyx is quinquefid; petals five; capsule polyspermous. There are 22 species; of which two only are British, the filipendula and ulmaria.

SPIRAL, in geometry, a curve line of the circular kind, which, in its progress, recedes from its centre.

A spiral, according to Archimedes, its inventor, is thus generated: If a right line, as AB (Plate Miscel. fig. 222), having one end fixed at B, is equally moved round, so as with the other end A to describe the periphery of a circle; and, at the same time, a point is conceived to move forward equally from B towards A, in the right line BA, so that the point describes that line, while the line generates the circle: then will the point, with its two motions, describe the curve-line B 1, 2, 3, 4, 5, &c. which is called the helix or spiral line; and the plane space, contained between the spiral line and the right line BA, is called the spiral space.

If also you conceive the point B to move twice as slow as the line AB, so that it shall get but half-way along the line BA when that line shall have formed the circle; and if then you imagine a new revolution to be made of the line carrying the point, so that they shall end their motion at last together; there will be formed a double spiral line, and the two spiral spaces, as you see in the figure. From the genesis of this curve, the following corollaries may be easily drawn. 1. The lines B 12, B 11, B 10, &c. making equal angles with the first and second spirals (as also B 12, B 10, B 8, &c.), are in arithmetical proportion. 2. The lines B 7, B 10, &c. drawn any how to the first spiral, are to one another as the arches of the circle intercepted betwixt BA and those lines. 3. Any lines drawn from B to the second spiral, as B 18, B 22, &c. are to each other as the aforesaid arches, together with the whole periphery added on both sides. 4. The first spiral space is to the first circle as 1 to 3. And, 5. The first spiral line is equal to half the periphery of the first circle; for the radii of the sectors, and consequently the arches, are in a simple arithmetic progression, while the periphery of the circle contains as many arches equal to the greatest; wherefore the periphery to all those arches is to the spiral lines as 2 to 1.

Spiral, in architecture and sculpture, implies a curve that ascends, winding about a cone or spire, so that all the points thereof continually approach the axis. It is distinguished from the helix, by its winding round a cone, whereas the helix winds in the same manner round a cylinder.

Spirals, *proportional*, are such spiral lines as the rhumb-lines on the terrestrial globe; which, because they make equal angles with every meridian, must also make equal angles with the meridians in the stereographic projection on the plane of the equator; and therefore will be, as Dr. Halley observes, proportional spirals about the polar point. See Rhumb.

SPIRITS, ardent. See Alcohol.

SPIRITUALITIES *of a bishop*, are the profits that he receives as a bishop, and not as a baron of parliament; such are the duties of his visitation, presentation-money, what arises from the ordination and institution of priests, the income of his jurisdiction, &c.

SPIT-INSECT, or Cuckow Spit. See Cicada.

SPLACHNUM, a genus of plants belonging to the class of cryptogamia, and order of musci. The antheræ are cylindrical, and grow on a large coloured apophysis or umbraculum. The calyptra is caducous. The female star grows on a separate stem. There are six species, the rubrum, luteum, sphæricum, ampullaceum, vasculosum, angustatum.

SPITTLE. See Saliva.

SPLEEN. See Anatomy.

SPLICING, in the sea-language, is the untwisting the ends of two cables or ropes, and working the several strands into one another by a fidd, so that they become as strong as if they were but one rope, &c.

SPONDEE, *spondæus*, in antient poetry, a foot consisting of two long syllables, as omnes. Some give the appellation spondaic to verses composed wholly of spondees, or at least that end with two spondees; as,

Constitit, atque oculis Phrygia agmina circumspexit.

SPONDIAS, *hog-plum*, a genus of the decandria pentagynia class of plants, the flower of which consists of five ovated, plane, and patent petals; and its fruit is an oval berry, containing four nuts in each cell. It is called monbin by Plumier. There are four species, trees of the West Indies.

SPONDYLUS, a genus of vermes testacea. The generic character is, animal a tethys; shell hard, solid, with unequal valves; one of the valves convex, the other rather flat; hinge with two recurved teeth, separated by a small hollow. There are four species. The gœderopus, which has a shell slightly eared and spinous, inhabits the Indian and other seas, and is found in infinite varieties as to size, thickness, and colours; sometimes entirely purple, orange, white, or bloom-colour; sometimes marked with various streaks. See Plate Nat. Hist., fig. 373.

SPONGIA, *sponge*, in natural history; a genus of animals belonging to the class of vermes, and order of zoophyta. It is fixed, flexible, and very torpid, growing in a variety of forms, composed either of reticulated fibres, or masses of small spines interwoven together, and clothed with a living gelatinous flesh, full of small mouths or holes on its surface, by which it sucks in and throws out the water.

Fifty species have already been discovered, of which 10 belong to the British coasts. 1. Oculata, see Plate Nat. Hist. fig. 374, or branched sponge, is delicately soft and very much branched; the branches are a little compressed, grow erect, and often united together. They have rows of cells on each margin, that project a little. This species is of a pale yellow colour, from five to ten inches high. The fibres are reticulated; and the flesh of the gelatinous part is so tender, that when it is taken out of the water it soon dries away. It is very common round the sea-coast of Britain and Ireland. This description will be better understood by observing that along the edges, and on the surface of the branches, are rows of small papillary holes, through which the animal receives its nourishment. 2. Cristata, or cock's-comb sponge, is flat, erect, and soft, growing in the shape of cock's combs, with rows of little holes along the tops, which project a little. It abounds on the rocks to the eastward of Hastings in Sussex, where it may be seen at low water. It is commonly about three inches long, and two inches high, and of a pale yellowish colour. When put into a glass of sea-water, it has been observed to suck in and squirt out the water through little mouths along the tops, giving evident signs of life. 3. Stuposa, tow-sponge, or downy branched sponge, is soft like tow, with round branches, and covered with fine pointed hairs. It is of a pale yellow colour, and about three inches high. It is frequently thrown on the shore at Hastings in Sussex. This sponge is so closely covered with a fine down, that the numerous small holes in its surface are not discernible. 4. Dichotoma, dichotomous or forked sponge, is stiff, branched with round, upright, elastic branches, covered with minute hairs. It is found on the coast of Norway, and also, according to Berkenhout, on the Cornish and Yorkshire coasts. It is of a pale yellow colour; and full of very minute pores, guarded by minute spines. 5. Urens or tomentosa, stinging sponge, or crumb-of-bread sponge, is of many forms, full of pores, very brittle and soft, and interwoven with very minute spines. It is full of small protuberances, with a hole in each, by which it sucks in and throws out the water. It is very common on the British coast, and is frequently seen surrounding fucuses. It is found also on the shores of North America, Africa, and in the East Indies. When newly taken out of the sea, it is of a bright orange-colour, full of gelatinous flesh; but when dry it becomes whitish, and when broken has the appearance of crumb of bread. If rubbed on the hand it will raise blisters; and if dried in an oven, its power of stinging is much increased, especially that variety of it which is found on the sea-coast of North America. 6. Palmata, palmated sponge, is like a hand with fingers a little divided at the top. The mouths are a little prominent, and irregularly disposed on the surface. It is found on the beach at Brighthelmstone. It is of a reddish colour, inclining to yellow, and of the same soft woolly texture with the spongia oculata. 7. Coronata, coronet sponge, is very small consisting of a single tube surrounded at the top by a crown of little spines. The tube is open at the top. The rays that compose the little crown are of a bright shining pearl-colour; the body is of a pale yellow. It has been found in the harbour of Emsworth, between Sussex and Hampshire. 8. Botryoides, grape sponge, is very tender and branched, as if in bunches: the bunches are hollow, and are made up of oblong oval figures having the appearance of grapes; and each bunch is open at top. This species is of a bright shining colour. The openings at the top are evidently the mouths by which the animal imbibes and discharges moisture. When the surface is very much magnified, it appears covered with little masses of triple, equidistant, shining spines. 9. Lacustris, creeping sponge, has erect, cylindrical, and obtuse branches. It is found in lakes in Sweden and England. 10. Fluviatilis, river sponge, is green, erect, brittle, and irregularly disposed in numerous branches. It abounds in many parts of Europe, in the fresh rivers of Russia and England, but particularly in the river Thames. It scarcely exhibits any symptoms of life, and is of a fishy smell: its pores or mouths are sometimes filled with green gelatinous globules. It differs very little from the lacustris.

So early as the days of Aristotle, sponges were supposed to possess animal life; the persons employed in collecting them having observed them shrink when torn from the rocks, thus exhibiting symptoms of sensation. The same opinion prevailed in the time of Pliny; but no attention was paid to this subject till count Marsigli examined them, and declared them vegetables. Dr. Peysonell, in a paper which he sent to the Royal Society in the year 1752, and in a second in 1757, affirmed they were not vegetables, but the production of animals; and has accordingly described the animals, and the process which they performed in making the sponges. Mr. Ellis, in the year 1762, was at great pains to discover these animals. For this purpose he dissected the spongia urens, and was surprised to find a great number of small worms of the genus of nereis or sea scolopendra, which had pierced their way through the soft substance of the sponge in quest of a safe retreat. That this was really the case, he was fully assured of, by inspecting a number of specimens of the same sort of sponge, just fresh from the sea. He put them into a glass filled with sea-water; and then, instead of seeing any of the little animals which Dr. Peysonell described, he observed the papillæ or small holes with which the papillæ are surrounded contract and dilate themselves. He examined another variety of the same species of sponge, and plainly perceived the small tubes inspire and expire the water. He therefore concluded, that the sponge is an animal, and that the ends or openings of the branched tubes are the mouths by which it receives its nourishment, and discharges its excrement.

SPONGIOSE, in anatomy, an appellation given to several parts of the body.

SPONSORS. See GODFATHERS.

SPONTANEOUS, or EQUIVOCAL, GENERATION. See EQUIVOCAL GENERATION.

SPONTOON, is a weapon much like a halberd, formerly used instead of a half-pike, by the officers of foot. When the spontoon was planted, the regiment halted; when pointed forwards, the regiment marched; and when pointed backwards, the regiment retreated.

SPOONBILL. See PLATALEA.

SPOONING, in the sea-language, is said of a ship, which being under sail in a storm at sea, is unable to bear it, and consequently forced to put right before the wind.

SPOTS, in astronomy. See MACULÆ.

SPOUT. See WATER-SPOUT.

SPRAT. See CLUPEA.

SPRING, in natural history, a fountain or source of water, rising out of the ground. See WATER.

Origin of springs. The water which falls on the surface of the earth, in rain, snow, &c. penetrates its substance till it meets with a stratum of clay, stone, or some other matter, which stops its descent; it then glides laterally on the stratum which sustains it, and in the direction to which it leans, till meeting with an aperture, it appears on the surface of the earth in the form of a spring. As water, like other matter, obeys the force of gravity, and therefore has a tendency to descend, springs are always lower than the source from which they are supplied. Springs are most common on the sides and at the bottom of mountains; they are seldom found quite at the summit of a mountain, and are rare where a country is every where level to a considerable distance, because there the strata are parallel, and do not conduct the water to any particular point. In order to obtain water, therefore, in flat countries, it is generally necessary to dig into the earth, when it is found to flow copiously from the sides of the opening, at no great distance from the surface. When wells are dug in elevated situations, water is seldom met with till we have dug to a considerable depth, and got below the general level of the country.

A curious circumstance occurs in the making of wells at Modena and Stiria in Italy. The workmen begin by digging through several strata or soils, till they come to a very hard kind of earth much resembling chalk; here they begin their mason-work, and build a well, which they carry on at their leisure till they have finished without being interrupted with one drop of water, and without any apprehension of not finding it when they come to make the experiment. The well being finished, they bore through the hard bed of chalk, upon which the well is built, with a long auger, but take care to get out of the well before they draw it out again; which when they have done, the water springs up into the well, and in a little time rises to the brim, nay sometimes overflows the neighbouring grounds. Now there can be little doubt, that these waters flow from reservoirs which are collected within the Appenine mountains, not far from Modena, and taking their course through subterraneous passages, endeavour to force their ascent to the same height from which they descend, wherever they can find a vent.

As all the water which falls in rain has undergone a natural distillation, it is much more pure when it first falls, than after it has passed through different strata of the earth and rises in springs. Spring water is always found to contain some foreign admixture; if this should be only an earthy salt, the water is called hard; if it contains other substances, it then receives the denomination of mineral water. See SOAP.

For intermitting springs, see HYDROSTATICS, Vol. I. p. 953.

Hot springs. There is no phenomenon which has more completely baffled the efforts of modern philosophy than this. The most probable hypothesis (though not satisfactory) is, that the same causes operate to produce these which produce volcanoes; but that their permanent temperature arises from the inflammatory matter being confined by an immense pressure, while the heat may be continued to a considerable degree in the earth, without exhibiting to our affrighted senses the formidable phenomenon of a volcanic fire. It must be acknowledged that it is in volcanic regions, that tepid waters are found in the greatest quantity; and it is in these that they display the most striking phenomena. At Laugervarm, a small lake, two days journey from mount Hecla, in Iceland, there are hot spouting springs, one of which throws up a column of water to the height of twenty-four feet. A piece of mutton and some salmon-trout were almost boiled to pieces, in six minutes, in one of these springs. At Geyser in the same island, there are forty or fifty spouting springs within the compass of three miles; in some the water is impregnated with clay, and white in its appearance; in some, where it passes through a fine ochre, it is as red as scarlet; in some it spouts forth in a continued stream; in others, at intervals like an artificial jet-d'eau. The largest which Von Troil observed had an aperture nineteen feet in diameter, through which the water spouted, at intervals, nine or ten times a day; round the top of it is a bason, which, together with the pipe, is in the form of a cauldron; the margin of the bason is nine feet higher than the conduit, and its diameter fifty-six feet. The water was thrown up in an immense column, at different times, to the height of from thirty to sixty feet, and at one time to the height of ninety-two feet. Previously to this explosion the earth began to tremble in three different places, and a noise was heard like a battery of cannon.

Another writer states, that at Geyser, in Iceland, there springs up a hot water, which upon cooling, deposits siliceous earth; and that of this very matter it has formed for itself a crater, in which columns of water, of a stupendous bulk, after they have been thrown to the height of ninety feet and upwards, fall, and are again received. The heat of the water during the explosion cannot be measured; but after it has risen and fallen through a stratum of air ninety feet thick, it raises the thermometer to 212°, which evinces that the heat in the bowels of the earth must be much more intense; and at this we shall cease to wonder when we consider, that in this case the subterraneous fire acts upon the water in caverns closed up by very thick strata of stones, an apparatus far more effective than Papin's digester. The crater was at first undoubtedly formed, and is daily strengthened, by siliceous earth, which quits the menstruum on its being cooled, falls down, and, being in somewhat like a soft state, concretes.

About sixty yards from the shore of the island of Ischia, at a place called St. Angelo, a column of boiling water bubbles on the surface of the sea with great force, and communicates its heat to the water of the sea near it. It boils winter and summer, and is of great use to the inhabitants in bending their planks for ship-building, &c. The fishermen also frequently employ this curious cauldron to boil their fish. Near the shore of this island sir William Hamilton found, when bathing in the sea, many spots where the sand was so intensely hot under his feet as to oblige him hastily to retire.

There is also a boiling spring near Viterbo, in the Roman state, called the Bullicame. It is a circular pool of about sixty feet in diameter, and exceedingly deep, the water of which is constantly boiling. It is situated in a plain surrounded by volcanic mountains. A stony concretion floats on the surface of the pool, which being carried off by the superfluous water, is deposited, and is constantly forming a labes or tufa, of which the soil all around the pool is composed.

These fountains are best accounted for by supposing the pipe or conduit to communicate with a large reservoir of water, which being subject to the heat of a volcanic fire, the steam generated in the reservoir by the boiling of the water acts forcibly on the water in the shaft or pipe, and ejects it by its elastic force in the form of a fountain, which will act with more or less vigour according to the degree of heat, and according to the resistance which the water encounters in its passage.

The most singular circumstance is the number of these springs which are found in almost every country; and even in those countries which have long ceased to be volcanic. England itself has its tepid springs, and those of Bath, Buxton, &c. are well known. Camden mentions, a well near Wigan, in Lancashire, which was called the burning well. If a candle was applied to its surface, he says, a flame was excited like that of ardent spirits set on fire, and the heat and inflammation thus excited would continue sometimes for the space of a whole day, and were sufficient to boil eggs, and even meat. Camden however mentions the well as having lost its inflammable property in his time; but he notices two others of a similar description, one in the same neighbourhood, and another in Shropshire. Should, then, the fact be as it is related by Camden, the philosophic reader will not find it difficult to explain the cause. The country where the well is, or was situated, abounds in coals. The well is therefore impregnated with naphta, or some bituminous vapour; this, upon the application of an ignited body, is capable of inflammation, and can even communicate a considerable portion of heat to the water of the well itself. There is no proof, however, that the Bath or Buxton waters are impregnated with any bituminous matter, though coals are plentiful in the neighbourhood; and as these waters contain a small portion of iron, there is reason to suppose them connected with beds of pyrites, or possibly with a latent subterraneous fire. On the whole we are not sufficiently acquainted with the internal parts of the earth to account satisfactorily for these and other phenomena of a similar kind; and whatever is advanced in the way of theory on these topics should be advanced with becoming diffidence, and rather with a view of exciting the attention and curiosity of others, than for the purpose of establishing a system unsanctioned by experiment, or building a reputation on the fallible basis of mere hypothesis. See WATERS, *Mineral.*

SPRING, in mechanics, denotes a thin piece of tempered steel, or other elastic substance; which, being wound up, serves to put several machines in motion by its elasticity, or endeavour to unbend itself: such is the spring of a clock, watch, &c.

The spring of a lock, gun, or pistol, is a piece of steel, violently bent; which, being set at liberty, beats back the bolt of the lock, or strikes down the cock.

SPRINGING *of a mast*, in the sea language, is when it cracks, but is not broken in any part of it; as the partners, hounds, &c.

SPRUCE-BEER, a cheap and wholesome liquor, which is thus made: Take of water sixteen gallons, and boil the half of it. Put the water thus boiled, while in full heat, to the cold part, which should be previously put into a barrel, or other vessel; then add sixteen pounds of treacle or molasses, with a few table-spoonfuls of the essence of spruce, stirring the whole well together; add half a pint of yeast, and keep it in a temperate situation, with the bung-hole open, for two days, till the fermentation is abated. Then close it up, or bottle it off, and it will be fit for being drunk in a few days afterwards. In North America, and perhaps in other countries, where the black and white spruce-firs abound, instead of adding the essence of the spruce at the same time with the molasses, they make a decoction of the leaves and small branches of these trees, and find the liquor equally good. It is a powerful antiscorbutic, and may prove very useful in long sea-voyages.

SPUNGE. See SPONGIA.

SPUNGING, in gunnery, the cleaning a gun's inside with a spunge, in order to prevent any sparks of fire from remaining in it, which would endanger the life of him who should load it.

SQUALUS, the *shark*, a genus of fishes of the order nantes. The generic character is; mouth situated beneath the anterior part of the head, with numerous teeth disposed in rows. Spiracles on each side the neck, in most species five in number, of a semilunar shape. Body oblong, somewhat cylindric. The animals of this genus are said to be much rarer in the Baltic than in any other sea: they are viviparous, and are observed to produce more young at a time than the rays, but each included, as in those fishes, in a quadrangular capsule or involucrum, each extremity of which is extended into a long, contorted, cartilaginous thread of great length. Many of the sharks are said to emit a phosphoric light during the night: they are chiefly of a solitary nature, and, in general, devour with indiscriminating voracity, almost every animal substance, whether living or dead; some few species however are observed to feed chiefly on fuci and other marine vegetables. There are 34 species, the most remarkable of which are,

1. Squalus carcharias. White shark. The great or white shark, so remarkable for its vast size and its powers of destruction, is an inhabitant of most parts of the globe, though much more frequently seen in the warmer than the colder latitudes: it is said to reside principally in the depths of the ocean, whence it rises at intervals in order to prowl for prey, and is considered as the most voracious of all the inhabitants of the deep. It arrives at the length of more than thirty feet, and is of a somewhat thicker or broader form than most of the genus: the head is of a depressed shape, and broad; terminating in front in an obtusely pointed snout: the mouth is of vast width, and furnished on the margin of each jaw with from three to six rows of strong flat, triangular, sharp-pointed, and finely serrated teeth, which are so imbedded in their investing cartilage as to be either raised or depressed at pleasure: the tongue is broad, thick, and

cartilaginous, and the throat extremely wide: the eyes, as in most of the genus, of a blueish or greenish cast, rather small, and half overhung by their skinny veil: the pectoral fins are large, strong, broad, and pointed: the first dorsal fin moderately large, somewhat falcated behind, and pointed: the second is situated very low on the back, near the origin of the tail, which is slightly lengthened, and of a bilobate shape, the upper lobe or division slightly pointed, and the lower or terminal lobe rather rounded: so great is the strength of this part, that even a young shark of about six feet in length is able by a stroke of its tail to break a man's leg; it is usual therefore with sailors to cut off the tail the instant they drag a shark on board: the anal fin is placed somewhat beyond the middle of the abdomen, and is of moderate size, and of a somewhat square outline: the general colour of the whole animal is a pale or whitish ash, darker or browner on the upper parts: the mouth is situated considerably beneath the front, for which reason the animal is said, like most others of this genus, to be obliged to turn on its back, or rather side, in order to seize its prey.

"Sharks (says Mr. Pennant) are the dread of sailors in all hot climates, where they constantly attend the ships, in expectation of what may drop overboard: a man that has that misfortune perishes without redemption: they have been seen to dart at him like gudgeons to a worm." They are said to attack negroes in preference to Europeans, and are observed in particular to attend with unremitting assiduity the passage of the slave-ships from the coasts of Africa to the West Indian islands, and, as Cepede very happily and justly observes, may be considered as forming a proper escort to the cruel conductors of those most accursed vessels. "A master of a Guinea-ship (says Pennant) informed me that a rage of suicide prevailed among his new-bought slaves, from a notion the unhappy creatures had, that after death they should be restored again to their families, friends, and country. To convince them that at least they should not reanimate their bodies, he ordered one of their corpses to be tied by the heels to a rope, and lowered into the sea; and though it was drawn up again as fast as the united force of the crew could be exerted, yet in that short space the sharks had devoured every part but the feet, which were secured at the end of the cord." The shark does not spare even its own species. A Laplander, according to Leems, had taken a shark, and fastened it to his canoe; but soon missed it, without being able to guess how: in a short time afterwards he caught a second of much larger size, in which, when opened, he found the one he had lost.

The internal parts of the shark present many remarkable particulars: the brain is small: the heart furnished with one ventricle and one auricle, which latter is of very large size, and receives the vena cava. In the stomach and intestines, according to Commerson, are usually found a great many tæniæ or tape-worms, which not only infest the cavities of these parts, but even penetrate into and lodge themselves between the interior coats: these animals, therefore, by their vellication and motions, must be supposed to aggravate the natural voracity of the shark, and to impel it to engorge a large quantity of food, in order to allay the sensations excited by these internal enemies: the milt, in the male fish, is disposed into two portions, and equals the length of about a third of the whole animal; and in the female the ovaries are of similar length. During the breeding-season, which takes place at different periods in different climates, the sharks are observed to approach the shores, in order to deposit their young in the most favourable situations: these are discharged, to the number of two or three at a time, still adhering to the capsule in which they had been before inclosed, and are excluded before the young animal has had time to break from it: the length of the newly-hatched shark does not exceed that of a few inches.

2. Squalus maximus, basking shark. This is a very large species, scarcely, if at all, inferior in size to the white shark; its length, according to Mr. Pennant, being from three to twelve yards, and even sometimes more. Great numbers of this species of shark were observed to visit the bays of Caernarvonshire and Anglesea in the summers of 1756 and a few succeeding years; continuing there only during the hot months, and quitting the coast about Michaelmas. They appear in the firth of Clyde, and among the Hebrides, in the month of June, in small shoals of seven or eight, but more frequently in pairs; and depart again in July. "They had nothing (says Mr. Pennant), of the fierce and voracious nature of other sharks, and were so tame as to suffer themselves to be stroked: they generally lay motionless on the surface, commonly on their bellies, but sometimes, like tired swimmers, on their backs: their food seemed to consist entirely of sea-plants, no remains of fish being ever discovered in the stomachs of numbers that were cut up, but the half-digested parts of algæ, &c." Linnæus says they feed on medusæ.

Mr. Pennant adds, that a shoal of this species will permit a boat to follow them without accelerating their motion till almost within contact, when it is usual for the harpooner to strike his weapon into them as near the gills as possible; but that they are often so insensible as not to move till the united strength of two men has forced in the harpoon deeper. As soon as they perceive themselves wounded, they fling up their tail, and plunge headlong to the bottom, and frequently coil the rope round them in their agonies, attempting to disengage the harpoon from them by rolling on the ground, for it is often found greatly bent. As soon as they discover that their efforts are in vain, they swim away with amazing rapidity, and with such violence, that there has been an instance of a vessel of seventy tons having been towed away against a fresh gale: they sometimes run off with two hundred fathom of line, and with two harpoons in them, and will employ the fishers for twelve, and sometimes for twenty-four hours, before they are subdued: when killed, they are either hawled on shore, or, if at a distance from land, to the vessel's side: the liver (the only useful part) is taken out, and marked out, and melted into oil in kettles provided for the purpose. A large fish will yield eight barrels of oil, and two of useless sediment. The fishers observed on these sharks a sort of leech, of a reddish colour, and about two feet long, but which fell off when the fish was brought to the surface of the water, and left a white mark on the skin.

3. Squalus catulus. Spotted shark. Lesser spotted dog-fish. Habit rather slender: length from two to three feet; head large; snout prominent, and slightly pointed; skin rough; body cylindric; colour pale brick-red, marked with very numerous, small, rounded, blackish, or dusky spots; abdomen whitish; both the dorsal fins placed much nearer to the tail than the head; ventral fins connate, large, and of a slightly pointed form; anal fin small; tail long, bilobate, with the lower lobe continued to a considerable distance beneath. Native of the European seas: a very voracious animal, preying on the smaller fishes, crabs, &c. According to Pennant it breeds from nine to thirteen young at a time, is very numerous on our own coasts, and very injurious to the fisheries: the liver is said to be highly noxious, causing long-continued stupor, succeeded by an universal itching, with a total desquamation of the cuticle.

4. Squalus stellaris. Rock shark, or greater spotted dog-fish. The general colour of this animal is a reddish grey, with round, unequal, blackish spots scattered over the whole body. The male and female are said to differ as to the disposition of spots. Native of the European seas, generally frequenting rocky places, and preying on various mollusca and crustacea. Its skin is used in commerce for the same purposes as those of other small sharks, and the flesh is esteemed somewhat more eatable than that of the former species. In Edwards's figure of the young of this fish, the body is represented as barred across the back with several broad brown bands.

5. Squalus ocellatus. Ocellated shark. Length about two feet and a half: colour ash-brown, with a few scattered dusky spots; back crossed by a few dusky bands; abdomen greenish-grey: teeth numerous, small, sharp, compressed, and dilated at the base: pectoral fins rounded, and of a dusky or blackish colour, edged with white; first dorsal fin situated beyond the ventral, marked at its anterior edge with two black spots, and emarginated behind; second of similar shape, but smaller: anal fin placed very near the tail, which is slightly sublobate. Native of the southern Pacific: observed about the coasts of New Holland during the first voyage of sir Joseph Banks.

6. Squalus zygæna. Hammer-headed shark. Perhaps the most deformed of all the marine animals. Length from five to fifteen or seventeen feet: habit rather slender; body subcylindric: head dilated on each side to a great extent; the eyes, which are very large, being placed at each extremity; mouth beneath, as in other sharks; teeth sharp, denticulated on each side, and disposed in three rows in each jaw; first dorsal fin rather large, of a somewhat falcated shape, and placed towards the upper part of the back; the second much smaller, and situated near the tail, which is rather short than long, and lobed beneath, the fin running on nearly as far as the vent; colour brown above, paler or whitish beneath. Native of the Mediterranean and Indian seas, where it is scarcely less voracious and formidable than even the white shark itself; attacking such as are accidentally exposed to its fury, or are incautiously bathing or swimming in its neighbourhood. It is observed about the coasts of the southern islands, and particularly of Otaheite, where the natives, trusting to their dexterity in swimming, appear to

hold it in but little dread, since they bathe without apprehension in places known to be infested by it. This fish is said to produce about ten or fourteen young at a birth. See Plate Nat. Hist. fig. 375.

7. Squalus pristis. Saw-snouted shark. The saw-fish is a large species of shark, growing to the length of fifteen feet or more: the head is slightly flattened at the top, and is produced in front into a very long, flat, straight, and slightly tapering bony snout, covered, like the rest of the animal, by minute scales: along the edges project a great number of very strong, large, slightly flattened, and very sharp-pointed toothlike processes: the mouth, as in other sharks, is placed beneath, and is furnished on the edges of the jaws with several rows of small and somewhat blunt teeth, paving the lips, as in some of the rays. The habit of the fish is rather slender; the body convex above, and somewhat flattened beneath; the dorsal fins placed as in the squalus acanthias and several others. The saw-fish is an inhabitant of the Mediterranean and northern seas, and was known to the ancient writers by the title of pristis. In the embryo animal the edges of the snout are observed to be nearly smooth, or but slightly undulated by the projection of the incipient teeth or processes, which are supposed to be of very quick growth.

SQUARE. See GEOMETRY.

SQUARE NUMBER, the product of a number multiplied into itself.

SQUARE, *in the military art*, a particular formation into which troops are thrown on critical occasions; particularly to resist the charge of cavalry.

SQUARE, *solid*, is a body of foot, where both ranks and files are equal. It was formerly held in great esteem; but when the prince of Nassau introduced the hollow square, this was soon neglected.

SQUARE, *hollow*, is a body of foot drawn up, with an empty space in the centre, for the colours, drums, and baggage, facing every way to resist the charge of the horse.

SQUARE, *oblong*, a square which is not at right angles, but represents the figure of an oblong, whose sides are unequal. Thus as eight companies of equal numbers would form a perfect square, ten make an oblong.

SQUARE, *perfect*, a square whose sides are equal and at right angles. The perfect square, in the formation of troops, seems best calculated for military movements and arrangements. Battalions, for instance, which are composed of eight companies, with one hundred rank and file in each, are equal to every species of disposition. It is upon this principle, we presume, that the French have distributed their infantry. British regiments, on the contrary, consist of ten companies, and are so composed that no square of this kind can be formed. This is manifestly a defect in our system. It is indeed remedied by the grenadier and light infantry companies being occasionally detached, or cast into separate battalions; so that the remaining companies, by being told off, are brought to eight equal parts.

SQUARE ROOT. See ALGEBRA, and ARITHMETIC.

SQUIRREL. See SCIURUS.

STACHYS, a genus of plants belonging to the class of didynamia, and order of gymnospermia; and in the natural system arranged under the 42d order, verticillatæ. The upper lip of the corolla is arched, the lower lip reflexed, and the larger intermediate lacinia is marginated. The stamina, after shedding the farina, are bent towards the sides. There are 24 species. Four only are natives of Britain; viz. 1. Sylvatica, hedge-nettle. The plant is hairy all over, erect, a yard high, and branched. The whole plant has a strong fetid smell. It grows commonly in woods and shady places, and flowers in July or August. It will dye yellow. 2. Palustris, clown's all-heal. The roots are white and tuberous. The stalk is branched at the bottom, and two or three feet high. The flowers are red or purple. This plant has a fetid smell and bitter taste, and is reckoned a good vulnerary. It grows on the sides of rivers and lakes, in low moist grounds, and sometimes in corn-fields. 3. Germanica, base horehound. The stem is downy, and about two feet high. The leaves are white, downy, wrinkled, and indented. The flowers are white, purplish within, and grow in multiflorous whorls. It grows in England. 4. Arvensis, corn-stachys, petty ironwort, or all-heal. The stalk is ten or twelve inches high, square, branched, and hairy. It is frequent in corn-fields, and grows from June to August.

STADIUM, an antient Greek long measure, about a furlong.

STÆHELINA, a genus of plants belonging to the class of syngenesia, and order of polygamia æqualis; and in the natural system arranged under the 49th order, compositæ. The receptacle is paleaceous, the chaff being very short; the pappus is branchy, and the antheræ caudated. There are 10 species, the gnaphaloides, dubia, arborescens, fruticosa, ilicifolia, corymbosa, chamæpeuce, imbricata, spinosa, and hastila.

STAG. See CERVUS.

STAG-BEETLE. See LUCANUS.

STALACTITÆ, or STALACTAGNIA, stony concretions resembling icicles, in natural history, or crystalline spars formed into oblong, conical, round, or irregular bodies, composed of various crusts, and usually found hanging in form of icicles from the roofs of grottoes, &c. See SPAR.

Of this class there are various species: as the hard, white stalactitæ; the white, shattery stalactitæ; and the yellow, shattery, crystalline stalactitæ. See Plate Nat. Hist. fig. 384.

STALAGMITIS, a genus of the monœcia order, in the polygamia class of plants; and in the natural method ranking under the 38th order, tricoccæ. The calyx is either quadriphyllous or hexaphyllous; the corolla consists of four or of six petals; the receptacle is fleshy, and somewhat square-shaped; the filaments about 30. In the hermaphrodite flower the stylus is short, thick, and erect; the fruit is a berry of a globular shape, unilocular, and browned with the stylus and stigma: they contain three oblong jointed triangular seeds. Of this there is only one species, viz. the cambogioides, a native of the East Indies and of the warmer parts of America. From this plant is obtained the gutta cambogia, or gum gamboge of the shops. See GUM RESINS, and GAMBOGE.

Till very lately botanists were at a loss for the true nature of the plant which yields this gum. Koenig, a native of Ireland, and an excellent botanist, travelled over a great part of India, and collected a great number of new plants, and among the rest the stalagmitis. These he bequeathed to sir Joseph Banks.

STALK. See BOTANY.

STAMINA. See BOTANY.

STAMINA, in the animal body, are defined to be those simple original parts, which existed first in the embryo. See PHYSIOLOGY.

STAMP DUTIES, a branch of the public revenue, raised by requiring, that all deeds or documents, in order to be valid, shall be written on paper or parchment bearing a public mark or seal, for which a tax is paid.

Stamp-duties are said to have originated in Holland, and were introduced into England in 1671, by "an act for laying impositions on proceedings at law:" these duties were very numerous, and were at first granted for nine years; they were afterwards continued for three years from 1680, when, in consequence of the unfortunate jealousies between the crown and parliament, they were suffered to expire. It was not long, however, before the necessities of the government caused this mode of taxation to be again resorted to as a source of revenue more to be depended on than some of the taxes which then existed: an act was accordingly passed in 1694, for imposing several duties upon vellum, parchment, and paper, which may be considered as the commencement of the present stamp-office, as a particular set of commissioners were then appointed for managing the duties; and about four years after, several new duties were granted, to continue for ever, to which numerous additions have at different times been since made.

The total gross produce of the stamp-duties, in the year 1713, was 107,779*l.*, the charges of management of which amounted to 14,296*l.*, leaving a nett produce of only 93,483*l.* In 1723, the nett produce had increased to 130,409*l.*; and it seldom exceeded this amount till 1757, when some new stamp-duties were imposed, by which the total nett amount of this revenue was increased to 267,725*l.*: in 1766 it amounted to 285,266*l.*; and no material additions were made till towards the conclusion of the American war. In 1782, a duty was imposed on fire-insurances, which, though not actually collected by means of stamps, was classed with the stamp-duties. In 1784, additional duties were laid on gold and silver plate. In 1785, duties were laid on post-horses, quack medicines, game-licences, attorneys' licences, and pawnbrokers; all of which were deemed stamp-duties, and considerably augmented the annual amount. But a far greater increase took place in the course of the war which began in 1793, during which new stamp-duties were imposed on receipts, bills of exchange, attorneys' articles, sea-insurances, licences to wear hair-powder, horse-dealers' licences, legacies, hats, stage-coaches, deeds, armorial bearings, small notes, medicines, and several other articles, which soon increased this branch of the revenue to more than double its former amount; and it is a mode of taxation which it is in general so difficult to evade, and is attended with such a comparatively small expence in collecting, that there can be little doubt that it will be extended as far as possible.

Total gross produce of the stamp-duties of

Great Britain, in the year ending 5th January 1806:

England and Wales	£3,931,616	8	$6\frac{3}{4}$
Scotland - -	262,669	4	$3\frac{1}{2}$
	£4,194,285	12	$10\frac{1}{4}$

This amount is subject to various deductions, as, the charges of management, discounts, and other parliamentary allowances, the cost of parchment and paper for the country distributors, an allowance to the two universities on almanacks, and many incidental expences, which reduced the actual nett produce paid into the exchequer to the following sums:

England and Wales	£3,672,793	5	2
Scotland - -	246,170	17	2
	3,918,964	2	4

The expence of collection amounted to 3*l*. 5*s*. per cent. on the gross revenue, or 3*l*. 9*s*. 5*d*. per cent. on the nett produce, which is considerably less than the management of this branch of the public income amounted to a few years back.

The total gross produce of the stamp-duties of Ireland for the year ending 5th January 1806, was 501,943*l*. 9*s*. $10\frac{1}{4}$*d*., and the nett sum paid into the exchequer 456,535*l*. 11*s*. $4\frac{1}{4}$*d*.; the expence of collection amounted to 5*l*. 0*s*. 1*d*. per cent. on the gross produce, or 5*l*. 7*s*. $6\frac{1}{4}$*d*. per cent. on the nett produce.

The following are the stamp-duties at present in force:

Actions, entry of, in inferior courts, for 40*s*. and upwards, 1*s*. 6*d*. 12 Geo. c. 22.

Acts. See Notarial Acts.

Adjudications, apprisings, charter, resignation, clare-constat, cognition of heirs, heritable right, confirmation, novodamus, principal and original instrument of surrender, retour, sasine, and service in Scotland, 9*s*. 6*d*. 37 Geo. III. c. 90.

Administration. See Probate.

Admiralty, or cinque-ports. Any answer exhibited in these courts, 7*s*. 41 Geo. III. c. 86.

Any libel, allegation, deposition, or inventory, exhibited in the courts of admiralty or cinque-ports, 5*s*. 37 Geo. III. c. 90.

Any copy of any citation, monition, or answer, made in the courts of admiralty or cinque-ports, 5*s*. 37 Geo. III. c. 90.

Any copy of any libel, allegation, deposition, or inventory, exhibited in the courts of admiralty or cinque-ports, 5*s*. 37 Geo. III. c. 90.

Any personal decree, warrant, or monition, in any court of admiralty, or the cinque-ports, or any copy thereof, 10*s*. 27 Geo. III. c. 90.

Any sentence given in the courts of admiralty or cinque-ports, or any attachment made out by the same, or relaxation thereof, 1*l*. 37 Geo. III. c. 90.

Any sentence or final decree exhibited in the courts of admiralty or cinque-ports, or any copy thereof, 4*s*. 37 Geo. III. c. 90.

Admission into corporations or companies, 8*s*. 37 Geo. III. c. 90.

Admission into any inn of chancery, 4*l*. 2*s*. 37 Geo. III. c. 90.

Admission into any of the four inns of court, 16*l*. 4*s*. 37 Geo. III. c. 90.

Admittance of fellow of college of physicians, attorney, clerk, advocate, proctor, notary, or other officer of any court whatsoever in Great Britain, except under 10*l*. per annum, 16*l*. 37 Geo. III. c. 50.

Advertisement in newspapers, 3*s*. 37 Geo. III. c. 50.

Advertisement in periodical pamphlets, 3*s*. 29 Geo. III. c. 50.

Advocate. See Admittance.

Affidavit in any court of law or equity, at Westminster, or in any court of great session for the counties in Wales, or in the court of the county palatine of Chester, or copies thereof, 2*s*. 35 Geo. III. c. 30.

Affidavits in inferior courts, 1*s*. 35 Geo. III. c. 30.

Agreements (except where the matter of agreement shall not exceed twenty pounds, and also except those for lease at rack rent) of messuages under five pounds, those for hire of labourers, artificers, manufacturers or menial servants, and those relating to sale of goods, &c. 10*s*. 37 Geo. III. c. 90.

No memorandum or agreement written upon an unstamped paper shall be deemed void, in case it is stamped at the head office and the duty paid within 21 days after the same shall have been entered into.

Allegation. See Citation.

Almanack, book or sheet, 8*d*. 37 Geo. III. c. 90.

Answer in court of equity. See Bills, copy.

Answer, sentence, and final decree, in ecclesiastical courts, and copies thereof, and copies of citation or monition, 2*s*. 23 Geo. III. c. 58.

Appeal, writ of. See Certiorari.

Appeal from the admiralty, arches, or prerogative courts of Canterbury or York, 12*l*. 37 Geo. III. c. 90.

Appearance on common bail, in the courts at Westminster, great sessions, or counties palatine, 1*s*. 6*d*. 32 Geo. II. c. 35. In all other courts, 1*s*.

Appearance on special bail, 2*s*. 10 W. III. c. 25.

Apprentices. The stamps upon apprentices' indentures amount to 25*s*. for each indenture, except parish-apprentices, or charity-children, for whom a sixpenny stamp is sufficient. Also where the fee given with the apprentice does not amount to 10*l*., each indenture is subject to a stamp of 15*s*. only. See Deeds.

And if a fee is given with an apprentice, clerk, or servant, bound or articled for a term of years, the following duty must be paid in respect of such fee:

From 1*l*. to 50*l*. sixpence for every pound.

All above 50*l*. and upwards, 1*s*. for every pound; to be paid by the master or mistress.

The full sum given must be set down in the indentures, or forfeit double the amount if the deception can be discovered.

And the indentures must be brought to the stamp-office: if executed within the bills of mortality, within one month; or if executed in the country, to their agents within two months after binding, and the duty paid, or the indentures become void, and forfeit 50*l*. besides.

Apprisings. See Adjudication.

Articles of clerkship. See Attorneys' clerks.

Assignments. See Deeds.

Assignments of bail-bonds, 1*s*. 10 W. III. c. 25.

Assurance of houses and policy. See Insurance.

Attachment in admiralty or cinque-ports, 1*l*. 37 Geo. III. c. 90.

Attested copies. See Copy.

Attorney, letter of. See Deeds.

Attorney, admittance of. See Admittance.

Every solicitor, attorney, notary, proctor, agent, or procurator, practising in any of the courts at Westminster, ecclesiastical, admiralty, or cinque-port courts, in his majesty's courts in Scotland, the great sessions in Wales, the courts in the counties palatine, or any other courts holding pleas to the amount of 40*s*. or more, shall take out certificates annually, upon which there shall be charged, if the solicitor, &c. reside in any of the inns of courts or in London, Westminster, Southwark, St. Pancras, St. Mary-le-bone, or within the bills of mortality, a stamp-duty of 5*l*.; in any other part of Great Britain, 3*l*. 25 Geo. III. c. 80.

And every solicitor, attorney, notary, proctor, agent, or procurator, in any court in England, holding pleas of 40*s*., shall annually, between November 1. and the end of Michaelmas term, deliver at the head office for stamps, a note containing his name and place of abode; and thereupon, and upon payment of the duties in respect of his abode, every such person shall be entitled to his certificate, to be issued by the commissioners of stamps, or their proper officer. 37 Geo. III. c. 90.

And every such certificate so obtained, shall be entered with the proper officer of the court where the party shall practise, who shall be paid 1*s*. for the entry, and the books of such entry may be inspected by all persons gratis.

And every such certificate shall bear date the 2d day of November, and shall cease on the 1st day of November next following.

Persons who shall, from and after the 1st day of November, 1797, act without obtaining a certificate, or without entering the same as aforesaid, or shall deliver in to any person at the stamp-office any account of a residence with intent to evade the higher duties, shall forfeit 50*l*. and be incapable of suing for any fees.

And every person admitted, sworn, inrolled, or registered in any of the courts, who shall neglect to obtain his certificate in manner aforesaid for the space of one whole year, shall from thenceforth be incapable of practising in his own name, or in the name of any other; but the courts may re-admit him on payment of the duty accrued since the expiration of his last certificate, and such further sum as the court shall order by way of penalty.

And by 39 and 40 Geo. III. c. 72. from and after November 1., 1800, every person who shall act as a public notary, or use or exercise the office of a notary in any manner, or do any notarial act whatsoever, without having been duly admitted in the court where notaries are usually admitted, and without having delivered in his name and usual place of residence, and taken out such certificate as is directed by the acts, shall forfeit 50*l*. and be incapable to do any act as a notary-public, or recover any fee.

Attorneys' clerks. By 34 Geo. III. c. 14, there shall be paid for every contract in writing, whereby any person shall become bound to serve as a clerk, in order to his admission as a solicitor or attorney, the additional duties following, viz. For every piece of vellum, parchment, or paper, upon which shall be written any such contract, whereby any person shall become bound to serve as a clerk as aforesaid, in order to his admission as a solicitor or attorney in any of the courts at Westminster, there shall be charged a stamp-duty of 100*l.*

And in order to his admission as a solicitor or attorney in any of the courts of great session in Wales, or in the counties palatine of Chester, Lancaster, or Durham, or in any court of record in England, holding pleas to the amount of 40*s.* and not in any of the said courts at Westminster, there shall be charged a stamp-duty of 50*l.*

Award, 10*s.* 37 Geo. III. c. 90.

Bail-bonds, and assignments thereof, 1*s.* 10 W. III. c. 25.

Beneficial warrant under sign manual (except for navy, army, or ordnance), 1*l.* 5*s.* 37 Geo. III. c. 90.

Bill of exchange, promissory or other note, draft, or order, where the sum amounts to 40*s.* and does not exceed 5*l.* 5*s.*, 6*d.* 41 Geo. III. c. 10.

Above 5*l.* 5*s.*, and not exceeding 30*l.*, 1*s.* 41 Geo. III. c. 10.

Above 30*l.*, and not exceeding 50*l.*, 1*s.* 6*d.* 41 Geo. III. c. 10.

Above 50*l.*, and not exceeding 100*l.*, 2*s.* 41 Geo. III. c. 10.

Above 100*l.*, and not exceeding 200*l.*, 3*s.* 41 Geo. III. c. 10.

Bills and notes not exceeding 200*l.* value, and for every bill of exchange, promissory or other note, draft or order, payable on demand, or otherwise, where the sum shall exceed 200*l.*, there shall be charged 4*s.* 41 Geo. III. c. 10.

Foreign bills of exchange, drawn in sets according to the custom of merchants, where the sum shall not exceed 100*l.*, 1*s.* 1*d.* 41 Geo. III. c. 10.

Above 100*l.*, and not exceeding 200*l.*, 1*s.* 6*d.* 41 Geo. III. c. 10.

And exceeding 200*l.* 2*s.* 41 Geo. III. c. 10.

Bill of lading, 2*s.* 37 Geo. III. c. 90.

Bill of Middlesex. See Original Writ.

Bills, answers, replications, rejoinders, demurrers, interrogatories, depositions taken by commissions, and other proceedings in courts of equity, 2*s.* 6*d.* 23 Geo. III. c. 58.

Bonds (except such as are given as security for money), 15*s.* 41 Geo. III. c. 86.

Coast bonds, and bonds on wills or administrations not exceeding 20*l.*, and bonds given by the widow of any soldier or sailor, are exempt from the duty imposed by 37 Geo. III. c. 90.

Bonds given as security for payment of money, if not above 100*l.*, 15*s.* 41 Geo. III. c. 86.

Above 100*l.*, and under 500*l.*, 1*l.* 37 Geo. III. c. 90.

If of 500*l.* or upwards, 1*l.* 10*s.* 37 Geo. III. c. 90.

When the amount shall be of the value of 100*l.* or upwards, 2*l.* 37 Geo. III. c. 90.

When the amount shall be of the value of 200*l.* or upwards, 3*l.* 37 Geo. III. c. 90.

When the amount shall be of the value of 5000*l.* or upwards, 5*l.* 37 Geo. III. c. 90.

Briefs for collecting charitable benevolence, &c. 4*l.* 23 Geo. III. c. 58.

Capias writ. See Original Writ.

Cards per pack, 2*s.* 6*d.* 41 Geo. III. c. 86.

Catalogue. See Inventory.

Certificate of barrister in any of the inns of court, 28*l.* 37 Geo. III. c. 90.

Certificate or debenture for drawback, 4*s.* 37 Geo. III. c. 90.

Certificate of marriage, except of seamen's widows, 5*s.* 5 W. III. c. 21.

Certificate. See Register, Registry, Sacrament.

Certiorari, writ of error, or writ of appeal, except to delegates, 10*s.*

Certificate to kill game, 3*l.* 3*s.* See Game.

Certificate of appointment of game-keeper, 10*s.* 6*d.*

Certificate for wearing hair-powder, 1*l.* 1*s.* 41 Geo. III. c. 69.

Certificate for attorneys. See Attorney.

Charter. See Adjudication.

Charter-party. See Deeds.

Charity-children's indenture. See Apprentice.

Citation or monition, libel or allegation, deposition or inventory, exhibited in any ecclesiastical court, and all copies thereof (except copies of citation or monition, for which see Answer), 2*s.* 6*d.* 23 Geo. III. c. 58.

Clare-constat. See Adjudication.

Clerk. See Admittance.

Clerks to attorneys. See Attorneys' Clerks.

Cognition of heirs. See Adjudication.

Collation, donation, or presentation to any ecclesiastical dignity, promotion, or benefice, of the yearly value of 10*l.* and upwards in the king's books, 12*l.* 37 Geo. III. c. 90.

And to any other benefice, dignity, or spiritual or ecclesiastical promotion, 6*l.* 37 Geo. III. c. 90.

Commission, ecclesiastical, 5*s.* 10 W. III. c. 25.

Common bail in the courts at Westminster, great sessions, or county palatine, 1*s.* 6*d.* 32 Geo. II. c. 35.

Confirmation. See Adjudication.

Contract. See Deed.

Conveyance, surrender, or grants of offices, release, or other deed inrolled in any court of record, or by any custos rotulorum, or clerk of the peace, 1*l.* 37 Geo. III. c. 90.

Copy of court-roll. See Surrender.

Copy of depositions in chancery, or other court of equity at Westminster, copy of any bill, answer, plea, demurrer, replication, rejoinder, interrogatories, or other proceedings whatsoever, in such courts of equity, 3*d.* 19 Geo. III. c. 66.

Copies of wills, 6*d.* 37 Geo. III. c. 90.

Any copy purporting to be a true copy, or attested to be a true copy, of any indenture, lease, or other deed, or any part thereof, for the security or use of any person, being a party to the same deed, and not having the custody of the original, or where such copy shall not be made in lieu of such original, 6*s.* 8*d.* 40 Geo. III. c. 72.

And the number of stamps required to be used for such copies of deeds is, one for every ten common law sheets of 72 words: but if after a calculation of that number, there shall remain a number of words less in quantity than ten common law-sheets, no further stamp is required for the excess.

And by 39 and 40 Geo. III. c. 72. from August 1, 1800, in lieu of the stamp-duty o 6*s.* 8*d.* upon the copy of any deed, when it is for the use of any person, other than any of the parties to the same deed, and who shall not have the custody of the original, or where such copy shall not be made in lieu of such original, there shall be paid a stamp-duty of 6*d.* on every piece of vellum or parchment, or sheet or piece of paper, on which any such copy shall be written.

And the number of stamps to be put upon every copy, is to be calculated according to the last act.

And by 39 and 40 Geo. III. c. 84. copies of indentures or other deeds, liable to the duties granted by 37 Geo. c. 90., may be stamped within sixty days after date of the attestation, on payment of the duty only.

Copy of any surrender of, and admittance to, any custom-right estate, not being copyhold, which shall pass by surrender and admittance only, and which shall not pass by deed, within England, Wales, and town of Berwick upon Tweed, 12*s.* 41 Geo. III. c. 86.

Copyhold estate. See Surrender.

Covenant, writ of. See Writ of Covenant.

Debenture for drawbacks. See Certificate.

Declaration, plea, replication, rejoinder, demurrer, or other pleading whatsoever, in any court of law at Westminster, or in any of the courts of the principality of Wales, or in any of the counties palatine of Chester, Lancaster, or Durham, and copies thereof, 3*d.* 32 Geo. II. c. 35.

Declaration, plea, replication, rejoinder, demurrer, or other pleading whatsoever, in any inferior court of law, and copies thereof, 2*d.* 10 W. III. c. 15.

Decree, personal. See Warrant.

Dedimus potestatem. See Original Writ.

Deeds. Any indenture (except parish-indentures), lease or deed-poll; and any charter-party, release, contract, or other obligatory instrument; or any procuration of letters of attorney; for every 15 common law-sheets, of 72 words each, 15*s.* 41 Geo. III. c. 86.

And moreover, by 37 Geo. III. there shall be paid upon every deed which shall be made after August 1, 1797, an additional stamp-duty of 10*s.* over and above all duties now payable on the vellum or paper whereon such deed shall be engrossed (but this is upon the first skin only), the provisions of this act being as follow:

It shall not extend to any bond or letter of attorney, bearing date before Aug. 1, 1797.

Also it shall not extend to any indenture of apprenticeship, where a sum not exceeding 10*l.* shall be given; nor to any lease for not exceeding twenty-one years, the full and improved value whereof, and rent reserved thereby, shall not be more than 10*l.* nor to any lease for lives, or years determinable on lives, where the fine shall not exceed 20*l.* nor the rent reserved 40*l.*

But by 39 and 40 Geo. III. c. 42, the above duties shall extend to every deed, which by lease may form, or is intended to form, a part of any conveyance of lands or tenements, whereby a greater interest in the same shall be conveyed than a term of twenty-one years, whatever may be the value thereof.

Nor shall any deed be subject to the payment of any greater duty than the sum before mentioned, or to be stamped on more than one skin, with the additional stamp; or to be stamped with more than one such stamp.

Nor shall the duty by this act imposed, be liable to the regulations respecting the stamping of parchment and paper, according to the number of common law-sheets engrossed thereon.

Upon payment, within sixty days after the date of the deed, of the duty hereby imposed, the stamp-officers may stamp any vellum, parchment, or paper, to which any deed shall have been engrossed, or on which any deed shall be intended to be engrossed with the additional stamp.

And if the duty shall not be paid within sixty days, then it shall be lawful to send the deed to the head office, and on payment of the duty, and the further sum of 10*l.* by way of penalty, the same may be stamped.

But grants, conveyances, and assurances, under the seal of the duchy of Lancaster, according to 19 Geo. III. c. 45. where the consideration does not exceed 10*l.* are exempted by that act, and 39 and 40 Geo. III. c. 72. from all duty.

The number of stamps required to be used on deeds, is, one for every fifteen common law-sheets (of seventy-two words each) contained in the deed, or in any schedule or instrument annexed thereto, or any indorsement thereon.

Deeds to be inrolled. See Conveyance.

Degrees in universities. See Register.

Demurrer at law. See Declaration.

Demurrer in equity. See Bills, copy.

Depositions in courts of equity. See Bills.

Depositions in ecclesiastical courts. See Citation.

Dice, per pair, and all other things used for any game of chance, 17*s.* 6*d.* 41 Geo. III. c. 86.

Dispensation to hold two ecclesiastical dignities, or benefices, or other dispensation from the archbishop of Canterbury, 20*l.* 37 Geo. 3. c. 90.

Donation. See Collation.

Draft for money. See Bill of Exchange.

Drawbacks. See Certificate.

Ecclesiastical commission. See Commission.

Entry, writ of. See Writ of Covenants.

Error, writ of. See Certiorari.

Exemplifications under the seal of any court, 2*l.* 37 Geo. 3. c. 90.

Faculty from the archbishop of Canterbury, or master of the faculty, 20*l.* 37 Geo. 3. c. 90.

Fellow of the college of physicians. See Admittance.

Final decree. See Answer.

Grant, or letters patent. Any grant or letters patent, under the great seal, or the seal of the duchy of Lancaster, of any honour, dignity, promotion, franchise, liberty, or privilege, or the exemplification thereof, 16*l.*. 37 Geo. 3. c. 90.

Grant from his majesty of money exceeding 100*l.*, which shall pass the great seal or privy seal, 12*l.* 37 Geo. 3. c. 90.

Grant of land in fee, lease for years, or other profits, not particularly charged under the great seal, seal of exchequer, duchy or county palatine of Lancaster, or privy seal, 10*l.* 37 Geo. 3. c. 90.

Grant of office or employment above 50*l.* a year, 6*l.* 12 Anne c. 9.

If above 100*l.* (to be calculated on the salary, fees, and perquisites), 12*l.* 37 G.3.c. 90.

Habeas corpus, 5*s.* 5 W. 3. c. 21.

Hats. Duty on every hat of 4*s.* or under, 3*d.* 36 G. 3. c. 12.

Above 4*s.* and not exceeding 7*s.*, 6*d.* 36 G. 3. c. 12.

Above 7*s.* and not exceeding 12*s.*, one shilling. 36 G. 3. c. 12.

Above 12*s.* and upwards, 2*s.* 36 Geo. 3. c. 12.

Heritable right. See Adjudication.

Horses. See Race-horses.

Indenture. See Deed.

Indentures, parish or charity. See Apprentices.

Institution, or licence ecclesiastical, in England, Wales, or Berwick upon Tweed (except licences of any ecclesiastical court or ordinary, appointing any stipendiary curate, in which the annual amount of the stipend shall be inserted), 1*l.* 10*s.* 37 G. 3. c. 90.

Instrument obligatory. See Deed.

Insurance of houses or goods from fire, 2*s.* per cent. 37 G. 3. c. 90.

Insurance upon any ship, goods, or merchandize, when the sum shall amount to 100*l.* five shillings, 41 G. 3. c. 10. and so progressively for every sum of 100*l.* insured.

And where the sum to be insured shall not amount to 100*l.* a like duty of five shillings. 41 G. 3. c. 10.

And where the sum to be insured shall exceed 100*l.* or any progressive sums of 100*l.* each, by any fractional part of 100*l.*, a like duty for each fractional part of 100*l.*, five shillings. 41 G. 3. c. 10.

And upon every insurance where the premium shall not exceed the rate of 20*s.* there shall be paid where the sum shall amount to 100*l.* a duty of 2*s.* 6*d.*: and so progressively for every sum of 100*l.* so insured. 41 G. 3. c. 10.

And where the sum to be insured shall not amount to 100*l.* a like duty of 2*s.* 6*d.*

And where the sum to be insured shall exceed 100*l.* or any progressive sums of 100*l.* each, by any fractional part of 100*l.* a like duty of 2*s.* 6*d.* 41 G. 3. c. 10.

Which duties shall be payable by the assured.

This does not extend to any insurance of houses, furniture, goods, wares, merchandizes, or other property, from loss by fire, already subject to duty, nor any insurance on lives. 41 G. 3. c. 10.

Interrogatories. See Bills, copy.

Inventories or catalogue of furniture with reference to any agreement, 5*s.* 37 Geo. 3. c. 90.

Inventory in ecclesiastical courts. See Citation.

Judgment. See Record.

Lading. See Bill of Lading.

Latitat. See Original Writ.

Lease of land, house, &c. See Deed.

Lease for years, or other profits, not particularly charged, under the great seal, seal of exchequer, duchy or county palatine of Lancaster, or privy seal, 10*l.* 37 G. 3. c. 90.

Lease by copy of court roll. See Surrender.

Legacies, wives, children, and grandchildren, to pay for a legacy or share of a personal estate.

Of the value of 20*l.* or under, 2*s.* 6*d.* 20 G. 3. c. 28.

Above 20*l.* and under 100*l.*, five shillings. 20 G. 3. c. 28.

For 100*l.* and upwards, 1*l.* 20 G. 3. c. 28.

Any other lineal descendant, or the father, mother, and other lineal ascendant, or the husband of the deceased, to pay for a legacy or share of a personal estate.

Of the value of 20*l.* or under, 5*s.* 23 G. 3. c. 58.

Above 20*l.* and under 100*l.* ten shillings. 23 G. 3. c. 58.

For 100*l.* two pounds. 23 G. 3. c. 58.

For 200*l.* three pounds. 23 G. 3. c. 58.

For 300*l.* four pounds. 23 G. 3. c. 58.

And for every further sum of 100*l.* two pounds. 29 G. 3. c. 51.

All collateral relations, and strangers, to pay for a legacy or share of a personal estate, under the value of 20*l.* five shillings. 23 G. 3. c. 58.

Letter of attorney for transfer or disposal of stock, or any other purpose, fiteen shillings. 41 G. 3. c. 86.

Letters of administration. See Probate.

Letters of mart. See Mart.

Letters patent. See Grant.

Libel. See Citation.

Licence ecclesiastical. See Institution.

Licence to pawnbrokers within the bills of mortality, 10*l.* per annum.

Out of the bills, 5*l.* per ann. 25 G. 3. c. 48.

Licence for marriage, 5*s.* 5 W. 3. c. 21.

Licence for selling quack medicines. See Medicines.

Licence for retailing beer and ale, 2*l.* 2*s.*

Licences for spirituous liquors, sweets, and wines, to be taken out annually at the excise-office.

Licence for a mad-house, 5*s.*

Licence to keep lying-in hospitals, 5*s.*

Licence to keep lottery-office, in London, Edinburgh, or Dublin, 50*l.*, elsewhere 10*l.*

Mandate. See Original Writ.

Marine Insurance. See Insurance.

Marriage licence. See Licence.

Mart, letters of, 1*l.* 10*s.* 37 G. 3. c. 90.

Matriculation in the universities, 8*s.* 37 G. 3. c. 90.

Medicines. See Quack Medicines.

Middlesex, bill of. See Original.

Monition. See Citation, Warrant.

Newgate, and general circuit pardon, 4*l.* 23 G. 3. c. 58.

Newspapers. Every newspaper, or paper containing public news, intelligence, or occurrences, contained in half a sheet or less, 3½*d.* 37 G. 3. c. 90.

Being larger than half a sheet, and not exceeding a whole sheet, 4*d.* 37 G. 3. c. 90.

Nisi prius. See Record.

Notary. See Admittance, and Attorney.

Notarial acts. Any protest or notarial act whatever, 4*s.* 37 G. 3. c. 90.

Note, promissory. See Bills of Exchange.

Novodamus. See Adjudication.

Obligatory instrument. See Bond.

Officer of any court. See Admittance.

Order for payment of money. See Bills of Exchange.

Order in any court of Westminster, and copy, 1*s.* 6*d.* 32 G. 2. c. 35.

Original Writ (unless præ capias), subpœna, bill of Middlesex, latitat, writ of capias, quo minus, writ of dedimus potestatem, every other writ, process, or mandate, for 40*s.* or upwards, 3*s.* 6*d.* 35 G. 3. c. 30.

Pamphlets of half a sheet, or less, ½*d.*

——— of one sheet, 1*d.*

——— per sheet, for every sheet in one copy of every pamphlet not exceeding six sheets in octavo, or a less size, twelve sheets in quarto, and twenty in folio, 2*s.*

Pardon of corporal punishment, crime, forfeiture, offence, or money above 100*l.* twelve pounds. 37 G. 3. c. 90.

Pardon. See Newgate Pardon.

Parish, charity indentures. See Apprentice.

Passports, 2*s.* 37 Geo. 3. c. 90.

Patents. See Grant.

Personal decree. See Warrant.

Plate. All gold plate made or wrought in Great Britain, except watch-cases, per oz. troy, 16*s.* 37 Geo. 3. c. 90.

And for every ounce troy of all silver plate, 1*s.* 37 Geo. 3. c. 90.

Plea at law. See Declaration.

Plea in equity. See Copy.

Pleadings in superior courts. See Bills, Copy, Declaration.

Pleadings in inferior courts. See Declaration.

Policy of assurance, on house, goods, or life, on any sum not exceeding 1000*l.* 6*s.* 25 Geo. 3. c. 58.

If above 1000*l.* eleven shillings. 17 Geo. 3. c. 50.

But by stat. 37 Geo. 3. c. 90. the above duties on policies, so far as the same relate to policies for insuring houses, furniture, goods, wares, merchandize, or other property, from loss by fire, are repealed from and after July 5, 1797, and from that period there shall be paid in lieu thereof:

For every policy of insurance, where the sum insured shall not amount to 1000*l.* the sum of 3*s.*

And where it shall amount to 1000*l.* or upwards, 6*s.* These policies are exempted from the additional ten shillings duty on deeds.

Policy of assurance upon ships. See Insurance.

Postea. See Record.

Presentation to any ecclesiastical dignity, promotion, or benefice, of the yearly value of 10*l.* and upwards in the king's books; 12*l.* 37 Geo. 3. c. 90.

And to any other benefice, dignity, or spiritual or ecclesiastical promotion, 6*l.* 37 Geo. 3. c. 90.

Probate of wills, or letters of administration, of any estate above 24*l.* and under 100*l.* ten shillings.

If the estate is of the value of 100*l.* and under 300*l.* two pounds ten shillings.

If the estate is of the value of 300*l.* and under 600*l.* eight pounds. 37 Geo. 3. c. 90.

If the estate is of the value of 600*l.* and under 1000*l.* fifteen pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 1000*l.* and under 2000*l.* thirty pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 2000*l.* and under 5000*l.* fifty pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 5000*l.* and under 10,000*l.* seventy-five pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 10,000*l.* and under 15,000*l.* one hundred and ten pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 15,000*l.* and under 20,000*l.* one hundred and sixty pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 20,000*l.* and under 30,000*l.* two hundred and ten pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 30,000*l.* and under 40,000*l.* three hundred and ten pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 40,000*l.* and under 50,000*l.* four hundred and ten pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 50,000*l.* and under 60,000*l.* five hundred and ten pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 60,000*l.* and under 70,000*l.* six hundred and ten pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 70,000*l.* and under 80,000*l.* seven hundred and ten pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 80,000*l.* and under 90,000*l.* eight hundred and ten pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 90,000*l.* and under 100,000*l.* nine hundred and ten pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 100,000*l.* and upwards, 1000*l.* 41 Geo. 3. c. 86.

And if any person shall administer any personal estate, without proving the will, or taking out letters of administration, within six months after the death of the party, such person shall forfeit 50*l.* to be recovered by action or information. 37 Geo. 3. c. 90.

Proctor. See Admittance.

Quack medicines, by 25 Geo. 3. c. 79. For every packet, box, bottle, pot, phial, or other inclosure, containing drugs, herbs, pills, waters, essences, tinctures, powders, or other preparation or composition whatsoever, used or applied externally, or internally, as medicines, or medicaments, for the prevention, cure, or relief, of any disorder or complaint, incident to, or in any wise affecting, the human body, which shall be uttered or vended in Great Britain, there shall be charged a stamp duty, after the rates following, viz.

Where the contents of any such packet, box, &c. shall not exceed the price of 1*s.* there shall be charged a stamp duty of 1½*d.*

Above 1*s.* and not exceeding			2*s.* 6*d.*,	3*d.*
2*s.* 6*d.*	-		4*s.*	6*d.*
4*s.*	-		10*s.*	1*s.*
10*s.*	-	-	20*s.*	2*s.*
20*s.*	-	-	30*s.*	3*s.*
30*s.*	-	-	50*s.*	10*s.*

And above 50*s.*, 20*s.*

Quó minus. See Original Writ.

Race-horses. For every horse entered to start or run for any plate, prize, sum of money, or any thing whatsoever, 2*l.* 2*s.*

Receipts. By 31 Geo. 3. c. 25, the following stamp duties shall be paid upon receipts:

For every piece of paper, &c. upon which shall be written, &c. any receipt, discharge, or acquittance for money, amounting to 40*s.* and not amounting to 10*l.*, two-pence.

Amounting to

10*l.* and not exceeding			20*l.*	4*d.*
20*l.*	-	-	50*l.*	8*d.*
50*l.*	-	-	100*l.*	1*s.*
100*l.*	-	-	200*l.*	2*s.*
200*l.*	-	-	500*l.*	3*s.*

Amounting to 500*l.* or upwards, 5*s.*

Receipt or discharge for legacies. See Legacies.

Recognizances and entries thereof, statute staple, or statute merchant, 1*l.* 37 Geo. 3. c. 90.

Record of nisi prius and postea, 5*s.* 10 W. 3. c. 25.

Register, entry, testimonial, or certificate of degree in any inn or court, 28*l.* 37 Geo. 3. c. 90.

Rejoinder at law. See Declaration.

Rejoinder at equity. See Bills, Copy.

Sasine and service. See Adjudication.

Sentence. See Answer.

Sentence in the admiralty. See Admiralty.

Significavit pro corporis deliberatione, 10*s.* 10 W. 3. c. 25.

Special bail, and appearance therein. See Appearance.

Statute merchant. See Recognizance.

Statute staple. See Recognizance.

Subpœna. See Original Writ.

Surrender of, or admittance to, any copyhold land or tenement in England, Wales, or Berwick upon Tweed; or grant, or lease, by copy of court-roll, or any other copy of court-roll, of any honour or manor, within the same parts, except the original surrender to the use of a will, and the court book or roll itself, 10*s.* 37 Geo. 3. c. 90.

And for every copyhold tenement of 20*s.* per annum mentioned in any surrender, for which a several fine shall be due, a distinct stamp duty shall be charged, if the tenements mentioned in the surrender shall, before June 22, 1797, have been surrendered by the different surrenders, and from and after 28 June, 1798, shall be added to any other tenement, or mentioned therewith, to be surrendered by the same surrender, 38 Geo. 3. c. 85.; and if any officer of a copyhold or customary court, shall receive a fine for any surrender without demanding the duty for each distinct tenement, he shall forfeit 20*l.* and if he shall receive the duties, and neglect to purchase the proper stamps for three months, he shall forfeit 5*l.* and double duty. 37 Geo. 3. c. 90.

Surrender, copy of. See Copy.

Surrender of grants or offices. See Conveyance.

Surrender, principal and original instrument of. See Adjudication.

Testimonial. See Register, and Registry.

Transfer of stock, in any company, society, or corporation, except the bank of England, or South-sea company, 1*l.* 37 Geo. 3. c. 90.

Transfers at the bank of England, 7*s.* 9*d.* 23 Geo. 3. c. 58.

Universities, degrees in. See Register.

Warrant, beneficial. See Beneficial Warrant.

Warrant, mandate, or authority, given to an attorney or solicitor, to carry on or defend a suit, &c. in any of the courts at Westminster, ecclesiastical, admiralty, or cinque port courts, or in his majesty's courts in Scotland, the grand session in Wales, or courts in the counties palatine, wherein the debt shall amount to 40*s.* or more, 2*s.* 6*d.* to be paid by the attorney, and not charged to the client. 25 Geo. 3. c. 80.

Warrant of attorney, to enter up judgment. See Letter of Attorney.

Wills. See Copy.

Wills, probate of. See Probate.

Writ. See Original Writ.

Writ of covenant for levying fines, 1*l.* 10*s.* 37 Geo. 3. c. 90.

Writ of entry, 1*l.* 10*s.*

Writ of error. See Certiorari.

Writ of habeas corpus, 5*s.*

STANDARD, in commerce, the original of a weight, measure, or coin, committed to the keeping of a magistrate, or deposited in some public place, to regulate, adjust, and try, the weights used by particular persons in traffic. The standards of weights and measures in England are appointed by Magna Charta to be kept in the exchequer, by a special officer, called the clerk or comptroller of the market.

The standard of gold coin is twenty-two carats of fine gold and two carats of alloy in the pound-weight troy; and the French, Spanish, and Flemish gold, is nearly of the same fineness. The pound-weight is cut into forty-four parts and a half, each current for twenty-one shillings. The standard of silver is eleven ounces and two pennyweights of silver, and eighteen pennyweights of alloy of copper. Whether gold or silver is above or below standard, is found by assaying, and the hydrostatical balance.

Standard, in military affairs, a measure by which men enlisted into his majesty's service, have the regulated height ascertained.

According to the regulations and orders published in 1799, the standard for men raised for the heavy cavalry shall be five feet seven inches, and for the light cavalry and infantry five feet five inches; but no recruits are to be taken, even of those sizes, who exceed thirty-five years of age, or who are not stout and well made. Lads between sixteen and eighteen years of age, who are well limbed, and likely to grow, may be taken as low as five feet six inches for the heavy cavalry, and as low as five feet four inches for the light cavalry and infantry. In those regiments which are specially authorised to enlist boys, healthy lads, under sixteen years of age, who are likely to grow, may be taken as low as five feet one inch. It will be recollected, that this standard is for men enlisted during a war; when regiments are put upon a peace establishment, a higher standard is resorted to. Thus by a letter, dated 28th January, 1802, it is directed, that the standard for the infantry of the line shall be five feet seven inches; that no man shall be enlisted who is above twenty-five years of age; but growing lads from seventeen to nineteen years of age, shall be taken as low as five feet five inches.

Standard, in war, a sort of banner or flag, borne as a signal for the joining together of the several troops belonging to the same body.

4

The standard is usually a piece of silk one and a half feet square, on which are embroidered the arms, device, or cypher, of the prince or colonel. It is fixed on a lance eight or nine feet long, and carried in the centre of the first rank of a squadron of horse, by the cornet.

Standards, belonging to the cavalry. Standards are posted in the following manner:

The king's, with the right squadron; the second with the left; and the third with the centre.

In advancing to the front on foot, the advanced standards and their serjeants must not slacken their pace, or deviate from right to left, as the lieutenant-colonel or leading officer may happen to do; but if he is in their way, they must call to him, because they alone regulate the march.

The standards must always be brought to the parade by a troop, viz. by that which has its private parade nearest to head-quarters. They must be accompanied by as many trumpeters as can conveniently assemble with that troop. Swords must be drawn, and the march sounded. The cornets parade, of course, with that troop to receive the standards. The standards are received by the regiment or squadron at open ranks, with swords drawn, officers saluting, and the march sounding by the remaining trumpeters. They must march off from head-quarters, and be lodged with the same form.

STANDING, in the sea-language. Standing part of the sheet, is that part of it which is made fast to a ring at the ship's quarter. Standing part of a tackle, is the end of the rope where the block is fastened. Standing ropes, are those which do not run in any block, but are set tawt or let slack, as occasion serves; as the sheet-stays, back-stays, &c.

STANGENSPATH, a sulphat of barytes, in bars: colour white; sometimes grey, red, green; always crystallized. The crystals are four-sided prisms, terminated by two-sided or four-sided summits, or six-sided prisms terminated by two-sided summits. Crystals very long and small, united in clusters. Longitudinal fracture, radiated cross, fracture even; brittle.

STANNARIES, the mines and works where tin is dug and purified, as in Cornwall, Devonshire, &c. There are four courts of the stannaries in Devonshire, and as many in Cornwall, and great liberties were granted them by several acts of parliament, in the time of Edward I. &c. though somewhat abridged under Edward III. and Charles I.

STANZA. See Poetry.

STAPELIA, a genus of the pentandria digynia class of plants, the corolla whereof consists of a large, plane, single petal, quinquefid beyond the middle; the fruit consists of two oblong subulated follicles, made up of only one valve, and containing one cell; the seeds are numerous, imbricated, compressed, and pappose. See Plate Nat. Hist. fig. 376.

Of this very curious genus, there are 49 species; though only two species were known to Linnæus, when he published his Species Plantarum, in 1762. They are all succulent plants of warm climates, and require either a dry store or a very good greenhouse. They should not be watered in the winter-season.

STAPES. See Anatomy.

STAPHYLEA, Bladder-nut, a genus of plants, belonging to the class of pentandria, and order of trigynia; and in the natural system arranged under the 23d order, trihilatæ. The calyx is quinquepartite. There are five petals. The capsules are three, inflated, and joined together by a longitudinal suture. The seeds are two, and are globose with a scar. There are three species. The pinnata, or bladder-nut tree, is a tall shrub or tree. The leaves are pinnated; the pinnæ are generally five, oblong, pointed, and notched round the edges. The flowers are white, and grow in whorls on long pendulous footstalks. This plant flowers in June, and is frequent in hedges about Pontefract and in Kent. The trifoliata, or three-leaved bladder-nut is a native of Virginia.

STAPHYLINUS, a genus of insects of the order coleoptera: the generic character is, antennæ moniliform; wing-sheaths halved, wings, covered; tail simple, protruding occasionally two oblong vesicles. In the genus staphylinus, which is pretty numerous, the wings which are rather large, are curiously pleated or convoluted beneath the short abruptly terminated wing-sheaths. The larger species are of an unpleasing appearance, and generally run with considerable swiftness. One of the most remarkable, as well as the largest of the British species, is the staphylinus major of Degeer, which is more than an inch long, entirely of a deep-black colour, and when disturbed, sets up the hinder parts of its body, as if in a posture of defence; it is very frequently seen, during the autumnal season, about sunny pathways, fields, and gardens, and is furnished with a large head, and very strong forcipated jaws. This species has often been quoted as the staphylinus maxillosus of Linnæus, but it appears from late observations to be a larger, and totally distinct species from that insect. There are nearly 200 species.

STAPLE, primarily signifies a public place or market, whither merchants, &c. are obliged to bring their goods to be bought by the people. Formerly the merchants of England were thus obliged to carry their wool, cloth, lead, and other staple-like commodities of this realm, in order to utter the same by wholesale: and these staples were appointed to be constantly kept at York, Lincoln, Newcastle upon Tyne, Norwich, Westminster, Canterbury, Chichester, Winchester, Exeter, and Bristol; in each of which a public mart was appointed to be kept, and each of them had a court of the mayor of the staple, for deciding differences, held according to the law-merchant in a summary way.

The staple-commodities of this kingdom are said by some to be these, viz. wool, leather, wool-fells, lead, tin, butter, cheese, cloth, &c. but others allow only the first five to be staple-commodities.

STAR. See Astronomy.

STARS, *falling*, in meteorology, meteors which dart through the sky in form of a star. See Meteors.

Mr. John Farey (Monthly Mag. xxii, 144) has given the name Satellitulæ, to the numerous masses of solid matter, probably composed of iron and nickel principally, which are supposed by him to be revolving in all directions round this earth in elliptical orbits; and which, by passing through the higher parts of the atmosphere, with the immense velocity peculiar to planetary motion, are rendered luminous for a short space, when in perigæo, and occasion the appearance of shooting-stars; which are found to move in all directions so numerously, that M. Benzenberg, in the space of one night, observed 500 of them (Monthly Mag. xxii. 223). The same masses, when they dip deeper into the atmosphere, being more heated, are supposed to appear as meteors; and, by the increasing resistance of the air in each of their revolutions, to fall at length to the earth in the fragments called meteoric stones, (see that article, where the opinions of different philosophers on the origin of these very curious substances may be seen.) In the same manner that Dr. Herschel uses the term asteroids, to express the planetary bodies revolving round the sun, which are smaller than the anciently known planets; satellitula are bodies, smaller than the moon, revolving round the earth as their centre of gravitation.

STAR. See HERALDRY.

STAR, in pyrotechny, a composition of combustible matters, which, being thrown aloft in the air, exhibits the appearance of a real star. See PYROTECHNY.

STAR-BOARD, in the sea-language, denotes the right-hand side of a ship: thus they say, star-board the helm, or helm a star-board, when he that conds would have the men at the helm, or steering-wheel, put the helm to the right side of the ship.

STAR-FISH. See ASTERIAS.

STAR-SHOT, a gelatinous substance frequently found in fields, and supposed by the vulgar to have been produced from the meteor called a falling-star; but, in reality, is the half-digested food of herons, sea-mews, and the like birds; for these birds, when shot, have been found to disgorge a substance of the same kind.

STAR-STONE, asteria, in natural history, a name given to certain extraneous fossil stones, in form of short, and commonly somewhat crooked, columns, composed of several joints; each resembling the figure of a radiated star, with a greater or smaller number of rays in the different species: they are usually found of about an inch in length, and of the thickness of a goose-quill. Some of them have five angles, or rays, and others only four; and in some the angles are equidistant, while in others they are irregularly so; in some also they are short and blunt, while in others they are long, narrow, and pointed; and some have their angles so very short and obtuse, that at first sight they might be taken for entrochoasteriæ. The several joints in the same specimen are usually all of the same thickness; this however is not always the case, but in some they are larger at one end, and in others at the middle, than in any other part of the body; and some species have one of the rays bifid, so as to emulate the appearance of a six-rayed kind.

STARCH. If a quantity of wheat-flour is formed into a paste, and then held under a very small stream of water, kneading continually till the water runs off from it colourless, the flour by this process is divided into two distinct constituents. A tough substance of a dirty-white colour, called gluten, remains in the hand; the water is at first milky; but soon deposits a white powder, which is known by the name of starch. A sweet-tasted mucilaginous substance remains dissolved in the water.

The starch obtained by this process is not altogether free from gluten; hence its colour is not very white, and it has not that fine crystallized appearance which distinguishes the starch of commerce. Manufacturers employ a more economical and more efficacious process. Good wheat, or the bran of wheat, is allowed to steep in cold water till it becomes soft, and yields a milky juice when squeezed. It is then taken out of the water; put into coarse linen sacks, which are subjected to pressure in a vat filled with water; a milky juice containing abundance of starch exudes, and mixes with the water of the vat. This process is repeated as long as the wheat yields any milky juice. The sack and its contents are then removed. The starch soon falls to the bottom of the vat; and the water which covers it gradually ferments, in consequence of the substances which it holds in solution. Alcohol and vinegar are formed in it; partly, no doubt, at the expence of the starch. The vinegar, thus formed, dissolves all the impurities, and leaves nothing behind but starch. It is then poured off, and the starch edulcorated with water. It is afterwards dried by a moderate heat. During the drying it usually splits into small columnar masses, which have a considerable degree of regularity. The water which has stood over the starch was analyzed by Vauquelin. It contains a considerable portion of alcohol and of acetic acid. The acid holds in solution gluten somewhat altered, phosphat of lime, and ammonia.

Starch was well known to the antients. Pliny informs us, that the method of obtaining it was first invented by the inhabitants of the island of Chio.

Starch has a fine white colour, and is usually concreted in longish masses; it has scarcely any smell, and very little taste. When kept dry, it continues for a long time uninjured though exposed to the air.

Starch does not dissolve in cold water, but very soon falls to powder, and forms with it a kind of emulsion. It combines with boiling water, and forms with it a thick paste. Linen dipt into this paste, and afterwards dried suddenly, acquires, as is well known, a great degree of stiffness. When the paste is allowed to cool, it assumes the form of a semi-transparent jelly; which, when dried by artificial heat, becomes brittle, and assumes an appearance not unlike that of gum. Hence it is supposed that starch, by being boiled in water, undergoes a certain degree of decomposition, which brings it nearly to the state of gum. When this paste is left exposed to damp air, it soon loses its consistency, acquires an acid taste, and its surface is covered with mould.

Starch is so far from dissolving in alcohol, even when assisted by heat, that it does not even fall to powder.

When starch is thrown into any of the mineral acids, at first no apparent change is visible; but if an attempt is made to reduce the larger pieces, while in acids, to powder, they resist it, and feel exceedingly tough and adhesive. Sulphuric acid dissolves it slowly, and at the same time a smell of sulphurous acid is emitted; and such a quantity of charcoal is evolved, that the vessel containing the mixture may be inverted without spilling any of it. Indeed, if the quantity of starch is sufficient, the mixture becomes perfectly solid. The charcoal may be separated by dilution and filtration. In muriatic acid starch dissolves still more slowly. The solution resembles mucilage of gum-arabic, and still retains the peculiar odour of muriatic acid. When allowed to stand for some time, the solution gradually separates into two parts: a perfectly transparent straw-coloured liquid below; and a thick, muddy, oily, or rather mucilaginous substance, above. When water is poured in, the muriatic smell instantly disappears, and a strong smell is exhaled, precisely similar to that which is perceived in corn-mills. Ammonia occasions a slight precipitate, but too small to be examined.

Nitric acid dissolves starch more rapidly than the other two acids; it acquires a green colour, and emits nitrous gas. The solution is never complete, nor do any crystals of oxalic acid appear unless heat is applied. In this respect starch differs from sugar, which yields oxalic acid with nitric acid, even at the temperature of the atmosphere. When heat is applied to the solution of starch in nitric acid, both oxalic and malic acid are formed, but the undissolved substance still remains. When separated by filtration, and afterwards edulcorated, this substance has the appearance of a thick oil, not unlike tallow; but it dissolves readily in alcohol. When distilled, it yields acetic acid, and an oil having the smell and the consistence of tallow.

The alkalies dissolve starch; but their action has not been examined with care. In pure potass it swells, and assumes the appearance of a transparent jelly. In this state the solution is soluble in alcohol.

When starch is thrown upon a hot iron, it melts, blackens, froths, smells, and burns with a bright flame like sugar, emitting, at the same time, a great deal of smoke; but it does not explode, nor has it the calomel smell which distinguishes burning sugar. When distilled, it yields water impregnated with an acid, supposed to be the pyromucous, a little empyreumatic oil, and a great deal of carbonic acid and carbureted hydrogen gas. The charcoal which remains is easily dissipated when set on fire in the open air; a proof that it contains very little earth.

Barley-grain consists almost entirely of starch, not however in a state of perfect purity. In the process of malting, which is nothing else than causing the barley to begin to vegetate, a great part of the starch is converted into sugar. During this process oxygen gas is absorbed, and carbonic acid gas is emitted. Water, too, is absolutely necessary; hence it is probable that it is decomposed, and its hydrogen retained. Starch, then, seems to be converted into sugar by diminishing the proportion of its carbon, and increasing that of its hydrogen and oxygen. Its distillation shews us that it contains no other ingredient than these three.

Starch is contained in a great variety of vegetable substances; most commonly in their seeds or bulbous roots, but sometimes also in other parts. Mr. Parmentier, whose experiments have greatly contributed towards an accurate knowledge of starch, has given us the following list of plants from the roots of which it may be extracted.

Arctium lappa,
Atropa belladonna,
Polygonum bistorta,
Bryonia alba,
Colchicum autumnale,
Spiræa filipendula,
Ranunculus bulbosus,
Scrophularia nodosa,
Sambucus ebulus,
——— nigra,
Orchis morio,
Imperatoria ostrutheum,
Hyoscyamus niger,
Rumex obtusifolius,
——— acutus,
——— aquaticus,
Arum maculatum,
Orchis mascula,
Iris pseudacorus,
— fœtidissima,
Orobosus tuberosus,
Bunium bulbocastanum.

It is found also in the following seeds;

Oats,	Millet,	Peas,
Rice,	Chesnut,	Beans,
Maize,	Horse-chesnut,	Acorn.

Indeed the greater number, if not the whole, of the vegetable seeds employed by man as an article of food, consists chiefly of starch. But that substance is always combined with some other which serves to disguise its properties; such as sugar, oil, extractive, &c. It is only by processes similar to those described in the beginning of this article, that it is extracted from these substances in a state of tolerable purity. The following substances, which may be considered as varieties of starch, deserve particular attention:

1. Potatoe starch. We are not yet in possession of a precise chemical analysis of the potatoe. When raw, its taste is exceedingly disagreeable, and it is said to be in some degree noxious; but it loses these qualities when boiled. The water acquires a deep brown colour, and the potatoe itself, when broken, appears to be composed of a congeries of fine soft shining crystals, to which it owes its mealy appearance. When exposed to the action of frost, it becomes soft, and acquires a very sweet taste. The nature of this change has not been examined into. When the potatoe is grated down to a pulp, and placed on a fine searce, if water is poured on it, a great deal of starch passes through the meshes of the searce, and may be collected in proper vessels. When washed with water and dried, it assumes a fine white colour, and possesses all the essential properties of starch. Indeed it goes much farther; a smaller quantity being sufficient to form a thick paste with water than is required of wheat-starch. It has a very perceptible crystallized appearance, and is much heavier apparently than common starch. It is not likely therefore that it could be employed with the same advantage as a hair-powder.

2. Sago. This substance is extracted from the pith of several species of palm in the Moluccas, Philippines, and other East Indian islands. The palm is cut into pieces of five or six feet in length; the woody part is cut off one side, exposing the pith lying, in a manner, in the hollow of a canoe. Cold water is poured in, and the pith well stirred; by which means the starch is separated from the fibrous part, and passes through with the water when the whole is thrown on a searce. The sago, thus separated, is allowed to settle; the water is poured off; and when it is half dry it is granulated, by being forced through a kind of funnel. It is said to acquire its grey colour while dried in an artificial heat. This substance is employed as an article of food, and its nourishing properties are well known.

3. Salop. This substance comes from Persia; but is said also to be manufactured in Europe. It is supposed to be the prepared roots of different species of orchis, as the morio, mascula, bifolia, pyramidalis. According to Moult, the bulbous roots of these plants are deprived of their cuticle, baked in an oven for ten or twelve minutes, which gives them their semitransparency, and then fully dried in a moderate heat. Like sago, salop is used as a nourishing article of food.

4. Cassava is prepared from the roots of the jatropha manihat, an American plant. They are peeled, and subjected to pressure in a kind of bag made of rushes. The juice that is forced out is a deadly poison, and is employed by the Indians to poison their arrows; but it deposits gradually a white starch, which when properly washed is innocent. What remains in the bag consists chiefly of the same starch. It is dried in smoke, and afterwards passed through a kind of sieve. Of this substance the cassava bread is made.

5. Sowans. This very nutritious article of food is made in this country from the husk of oats, by a process not unlike that by which common starch is made. The husk of the oat (called seeds) is separated from oatmeal by the sieve. It still retains a considerable portion of farinaceous matter, which forms a very nourishing food.

STARLING. See STURNUS.

STATICE, THRIFT, a genus of plants belonging to the class of pentandria, and order of pentagynia; and in the natural system ranging under the forty-eighth order, aggregatæ. The calyx is monophyllous, entire, folded, and scaricose. There are five petals, with one superior seed. There are thirty-nine species; three of these are British plants. 1. The armeria, thrift, or sea gilly-flower, has a simple naked stem about six inches high. The radical leaves are like grass. The flowers are terminal, pale red, with a round head, and not very large. This plant flowers in July or August, and grows in meadows near the sea. 2. Limonium, sea-lavender. The stem is naked, branched, and about a foot high. 3. Reticulata, matted sea-lavender. The stem is prostrate, and terminated by a panicle of flowers. This species is also found on the sea-coast of South Britain.

STATICS, that branch of mathematics which considers the motion of bodies arising from gravity. See MOTION.

Statics then is the doctrine, or theory, of motion, considered merely as arising from the weight of bodies; in which sense it is distinguished from mechanics, which is the application of statics to machines, engines, &c. though, it must be owned, that statics and mechanics are frequently confounded. See MECHANICS. For the laws and principles whereon the doctrine of statics is founded, see the articles GRAVITY, GRAVITATION.

STATIONARY. See ASTRONOMY.

STATISTICS, a word lately introduced to express a view or survey of any kingdom, county, or parish.

A grand and extensive work of this kind was undertaken in Scotland in the year 1790 by sir John Sinclair, whose patriotic exertions in favour of his country will be gratefully remembered by posterity. The great object of it is to give an accurate view of the state of the country, its agriculture, its manufactures, and its commerce; the means of improvement, of which they are respectively capable; the amount of the population of a state; and the causes of its increase or decrease: the manner in which the territory of a country is possessed and cultivated; the nature and amount of the various productions of the soil; the value of the personal wealth or stock of the inhabitants, and how it can be augmented; the diseases to which the people are subject, their causes and their cure: the occupations of the people; where they are entitled to encouragement, and where they ought to be suppressed; the condition of the poor, the best mode of maintaining them, and of giving them employment; the state of schools, and other institutions, formed for purposes of public utility; the state of the villages and towns, and the regulations best calculated for their police and good government; the state of the manners, the morals, and the religious principles of the people, and the means by which their temporal and eternal interests can best be promoted.

STATUARY, a branch of sculpture, said to be the invention of Dædalus, amidst other productions of ingenious talents: others assert him to have been only the improver of an art known long before his time, and that he was the first who endeavoured to give the appearance of motion and action to figures.

The Phenicians are said to have been the first who erected statues in honour of their gods; but, if we believe the accounts generally given of the Phenician worship, the religious statuary of that nation did not exhibit human forms, but merely pointed stones or other symbolical expressions of their divinities.

STATUES, are figures, representing living or deceased creatures, of whatever species, real or imaginary; and carved, cast, modelled, or moulded, in full relievo, insulated on every part.

Statues are formed with the chisel, of several materials, such as marble, stone, &c.: they are carved in wood; or cast in plaister of Paris, or other matter of the same nature; they are also cast in several metals, as lead, brass, silver and gold.

Statues are divided into

Colossal, or considerably exceeding the dimensions of nature; as, for instance, the celebrated statue of Apollo, at Rhodes.

Allegorical, or such as, under human or other symbolical forms, represent subjects of a different kind, as Time, Ocean, Winds, or qualities of an intellectual nature, as Mercy, Justice, &c. &c.

Statues of deities, demi-gods, and heroes were, among the antients, generally represented somewhat larger than life.

Monumental, either representing the person, the virtues, or the actions of the deceased.

Equestrian, generally of some illustrious person on horseback.

Pedestrian; or on foot.

The most celebrated statues are those of the Egyptians, Grecians, and Romans. Of the Egyptian statues, sufficient has been said under the article sculpture. See SCULPTURE. Of the Grecian and Roman we propose to add some important particulars.

STATUES, *antique*. The denomination of antique statues is applicable to all antient statues, found either in India, Egypt, &c.; but is especially given, in preference, to the statues wrought by the antient Greek and Roman sculptors. The works of the Grecians are considered as the most perfect examples of sculpture. Their statues are eminently admirable for the various beauty of their forms, for characteristic expression and grace. See SCULPTURE.

The Grecian statues of men are generally naked. The Roman are clothed agreeably to the manner of the country, and are distinguished into

Paludatæ (statuæ), those of emperors with long robes over their armour.

Loricatæ, those of soldiers with cuirasses.

Thoracatæ, those with coats of armour.

Togatæ, those of magistrates with the toga, or robe worn in office.

Trabeatæ; those of senators and augurs.

Tunicatæ, those clothed with a plain tunic.

Stolatæ, those of women with long trains.

The antique statues are most particularly remarkable for their systematic representation of the human form. As the principle most apparent in their system is that of proportions, we shall give, first, an account of their general proportions to which they chiefly adhered, and next, an accurate measurement of the various parts of the body, taken at Rome, from some of their most celebrated original statues.

It is to be observed, however, that although the inferior antique possesses little other merit than that of proportion, the excellence of the finer works of Greece is of a much more comprehensive description.

Proportions of the antique statues.

Proportion is the basis of beauty, and there can be no beauty without it; on the contrary, proportion may exist where there is little beauty. Experience teaches us, that knowledge is distinct from taste; and proportion, therefore, which is founded on knowledge, may be strictly observed in any figure, and yet the figure have no pretensions to beauty. The antients considering ideal beauty as the most perfect, have frequently employed it in preference to the beauty of nature.

It is probable that the Grecian, as well as the Egyptian artists, determined the great and small proportions by fixed rules; that they established a positive measure for the dimensions of length, breadth, and circumference. This supposition alone can enable us to account for the great conformity which we meet with in antient statues. Winkelman thinks that the foot was the measure which the antients used in all their great dimensions, and that it was by the length of it that they regulated the measure of their figures by giving to them six times that length. This, in fact, is the length which Vitruvius assigns, L. 3, cap. 1. That celebrated architect thinks the foot is a more determinate measure than the head or the face, the parts from which modern painters and sculptors often take their proportions. This proportion of the foot to the body, which has appeared strange and incomprehensible to the learned Huetius, and has been entirely rejected by Perrault, is, however, founded upon experience. After measuring with great care a vast number of figures, Winkelman found this proportion not only in Egyptian statues, but also in those of Greece. This fact may be determined by an inspection of those statues, the feet of which are perfect; and one may be more fully convinced of it by examining some figures of the Greek divinities, in which the artists have made some parts beyond their natural dimensions. In the Apollo Belvedere, which is a little more than seven heads high, the foot is three Roman inches longer than the head. The head of the Venus de Medicis is very small, and the height of the statue is seven heads and a half; the foot is three inches and a half longer than the head, or precisely the sixth part of the length of the whole statue.

Other writers are of opinion, that the following rules form a principal part of the system of Grecian sculpture:

The body consists of three parts, as well as the members. The three parts of the body are, the trunk, the thighs, and the legs. The inferior part of the body are the thighs, the legs, and the feet. The arms also consist of three parts. These three parts must bear a certain proportion to the whole, as well as to one another. In a well formed man, the head and body must be proportioned to the thighs, the legs, and the feet, in the same manner as the thighs are proportioned to the legs and the feet, or the arms to the hands. The face also consists of three parts, that is, three times the length of the nose; but the head is not four times the length of the nose, as some writers have asserted. From the place where the hair begins to the crown of the head, are only three-fourths of the length of the nose, or that part is to the nose as 9 to 12.

MEASUREMENTS TAKEN AT ROME FROM ORIGINAL ANTIQUE STATUES.

Hercules (Farnese).

Length of the face as nearly as can be found, 11 inches and a half.

From the pit between the clavicles to the bottom of the belly, 2 feet 10 inches.

From the point of the (right) os ilium to the top of the petella, the same, viz. 2 feet 10 inches.

From the top of the patella to the sole of the right foot, 2 feet 10 inches and a half.

From the top of the head as nearly as can be guessed, to the bottom of the belly, 4 feet 2 inches and a half.

From the bottom of the belly to the sole of the foot, 5 feet 2 inches and three-fourths.

Colossal Commodus (of the Capitol).

Length of the face from the top of the forehead to the bottom of the chin, as nearly as can be guessed, (the hair being down on the forehead) 3 feet 2 inches.

Flora (Farnese).

From the pit between the clavicles to the bottom of the belly; from the point of the (right) os ilium to the centre of the patella; and from the centre of the patella to the sole of the foot, exactly equal.

From the pit between the clavicles to the right nipple, 14 inches and a half.

From the bottom of the belly to the sole of the foot, 5 feet 8 inches.

Length of the leg from the centre of the patella to the sole of the foot, 3 feet 1 inch.

The measurements of the four following female statues, have for their rule the real length of their respective faces, divided into three parts, and those parts subdivided into twelve minutes. See Plate No. 9, (entitled Antique Statues.)

Venus de Medicis.

From the bottom of the right ear to the pit between the clavicles, 3 parts.

From the bottom of the left ditto to the said pit, 2 parts 9 minutes.

From the said pit to the bottom of the sternum, as near as can be found, 3 parts 6 minutes and one-third.

From the said pit to the bottom of the belly, as near as can be found, 9 parts 1 minute and three-fourths.

From the point of the (right) os ilium, as near as can be found, to the centre of the patella, 9 parts 4 minutes and one-third.

From the said pit to the right pap, 3 parts 5 minutes; to the left ditto, 3 parts 6 minutes.

From the centre of the right patella to the sole of the foot, 9 parts 8 minutes and one-third.

From the point of the left ilium, as near as can be found, to the centre of the patella, 9 parts 1 minute.

From the centre of the said patella to the sole of the foot, 9 parts.

Length of the right foot from the heel to the joint of the great toe, 4 parts 9 minutes and two-thirds.

Length of the left ditto, 4 parts 8 minutes.

Breadth of the face from ear to ear, 2 parts 3 minutes.

From the right ear to the tip of the nose, 2 parts 1 minute and one-third.

Thickness of the neck, measured with the face in front, 1 part 11 minutes and a half.

Distance from pap to pap, 3 parts 11 minutes.

From point to point of the ileum, as near as can be found, 4 parts and half a minute.

Breadth of the shoulder, just below the heads of the humerus, measured obliquely, viz. parallel with the shoulders, 7 parts 9 minutes and a half.

Breadth of the breast, from the point where the pectoral and deltoid muscles join, 5 parts 5 minutes and one-fourth.

Narrowest part of the body, a little above the navel, 4 parts 9 minutes and a half.

Breadth of the hips, measured upon the ilium under the obliq. descend. 6 parts 4 minutes and a half.

Thickest part of the right thigh measured as near as can be across the centre of the rectus, 3 parts 6 minutes.

Thickness of the said knee across the centre of the patella, 2 parts 1 minute.

Thickest part of the calf of the said leg, 2 parts 2 minutes and a half.

Small ditto, just above the ancle, 1 part 2 minutes and three-fourths.

Thickness of the said ancle from centre to centre of each bone, 1 part 5 minutes and one-fourth.
Thickness of the left knee measured across the patella, 2 parts.
Thickest part of the calf of the left leg, 2 parts 2 minutes.
Small ditto, just above the ancle, 1 part 2 minutes.
From centre to centre of the ancle bones of the left leg, 1 part 4 minutes and one-fourth.
Breadth of the left foot upon the joints, at the roots of the toes, 1 part 9 minutes.
Length from the head of the deltoid to the tip of the left elbow, 7 parts; right ditto, 7 parts 2 minutes.
Length of the lower right arm from the tip of the elbow to the centre of the wrist bone, 4 parts 11 minutes.
Length of the left ditto, ditto, 5 parts 1 minute, and two-thirds.
Thickest part of the right arm above the elbow, 1 part 11 minutes.
Thickness of the lower arm, measured with the back of the hand in front, 1 part 8 minutes and a half.
Ditto of the said wrist from bone to bone, 1 part three-fourths of a minute.
Thickest part of the left arm, measured in front, 1 part 9 minutes and a half.
Thickness of the lower arm ditto, measured like the former, 1 part 7 minutes and one-fourth.
Thickness of the said wrist from bone to bone, 1 part and one-half minute.
From the centre of the wrist to the root of the middle finger, 1 part 10 minutes.
Length of the middle finger, 1 part 8 minutes and one-fourth.
Breadth of the hand across the joints at the roots of the fingers, 1 part 4 minutes and a half.
Ditto of the body from the most prominent part of the breast bone to ditto of the shoulder behind, measuring and observing the curve of the figure, 4 parts 2 minutes and one-third.
Narrowest part of the body, measured from the hollow above the navel, to the most prominent part of the sacro-umbalis, observing the curve of the figure, 3 parts 10 minutes.
Distance from the navel to the bottom of the belly, 4 parts and one-half minute.
Length from the point of the (left) os ilium, as near as can be found, to the most prominent part of the glutæus below, 5 parts.
Distance from ditto to ditto, of the right side, 4 parts 7 minutes.
Thickest part of the right thigh in profile, from the centre of the rectus, 3 parts 7 minutes.
Thickness of the said knee in profile from the centre of the patella, 2 parts 4 minutes and two-thirds.
Ditto of the calf of the right leg, in ditto, 2 parts 3 minutes; smallest part ditto, 1 part 5 minutes and one-fourth.
Thickness of the left thigh from just under the glutæus to the rectus above in profile, 3 parts 8 minutes.
Ditto of the left knee, in profile, from the centre of the patella, 2 parts 4 minutes.
Thickness of the said leg above, 2 parts 4 minutes; ditto of ditto at the small, 1 part 5 minutes and one-fourth.
Total length of the figure, allowing 4 parts for the head, and measuring down the centre of the figure, 31 parts 11 minutes and a half.

Flora Vestita, or draped.

From the bottom of the ear to the pit between the clavicles, 2 parts 8 minutes and a half.
Length of the neck from where it joins the bottom of the chin to the said pit, 1 part 4 minutes.
From the said pit to the right nipple, 3 parts 5 minutes and a half; left ditto, 3 parts 2 minutes.
From the pit between the clavicles to the bottom of the belly as near as can be guessed, 11 parts 10 minutes.
From nipple to nipple, 3 parts 7 minutes and a half.
From the roots of the hair on the forehead to the sole of the foot, 10 faces, or 30 parts 8 minutes.
Length of the leg bent from the top of the patella to the sole of the foot, 9 parts 3 minutes.

Cleopatra of the Belvidere.

From the bottom of the chin to the pit between the clavicles, 1 part 7 minutes.
From the tip of the right ear to the said pit, 3 parts 3 minutes.
From the said pit to the left nipple, 3 parts 4 minutes; right ditto 3 parts.
Total length of the body, as it lies, from the said pit to the bottom of the belly, 9 parts 4 minutes.
From the bottom of the belly to the middle of the patella, as near as can be guessed, 9 parts 2 minutes.
From the middle of the patella to the instep, 9 parts 5 minutes.
From the instep to the sole of the foot within, 1 part 9 minutes.
Length of the left arm underneath, from where it joins to the pectoral, to the point of the elbow, 5 parts 9 minutes.
From the same elbow to the joint of the wrist, 5 parts 6 minutes and a half.
Thickness of the same arm above the elbow, measured from underneath, to about where the deltoid muscle is inserted, 2 parts 5 minutes.
Thickest part of the same arm below the elbow, 2 parts 3 minutes.
Breadth of the wrist from bone to bone, 1 part 5 minutes.
Thickness of ditto from the centre below to the centre above, 9 minutes.
Breadth of the body across the breasts as near as can be measured, 7 parts 3 minutes.
Ditto of ditto, as near, &c. across the belly just below the navel from hip to hip, 7 parts 10 minutes and a half.
Breadth from nipple to nipple, 4 parts 3 minutes.
Thickness of the upper thigh, measured over and across about the middle, 3 parts 10 minutes and a half.
Ditto knee ditto, across the middle of the patella, 2 parts 9 minutes and a half.
Calf of the leg, ditto, 2 parts 10 minutes and a half.
Ancle ditto from bone to bone, 1 part 7 minutes and a half.
Total length of the figure, allowing 1 part above the roots of the hair upon the forehead, and measuring down the middle of the figure, down the centre of the uppermost thigh and leg to the sole of that foot, as near as can be known, somewhat less than 36 parts.
Breadth of the right foot from the joint at the root of the great toe to the joint on the other side at the root of the little toe, 2 parts 3 minutes.
Length of the great toe from the centre of the joint, 1 part 7 minutes.

Beautiful daughter of Niobe.

From the chin next the throat to the pit between the clavicles, 1 part 10 minutes.
From the tip of the left ear to ditto, 3 parts 1 minute and a half.
From the tip of the right to ditto, 2 parts 7 minutes and three-fourths.
From the said pit to the left nipple, 2 parts 10 minutes.
From ditto to the right nipple, 3 parts 2 minutes.
From nipple to nipple, as near as can be guessed, 4 parts.
Length of the body from the pit between the clavicles to the bottom of the belly, 9 parts.
From the point of the ilium, (guessed) to the centre of the patella, 8 parts 5 minutes.
From the centre of the patella to the sole of the foot, 8 parts 8 minutes and a half.

The measurements of the following male figures, have for their rule, the real length of their respective heads, divided into four equal portions, called fourths, and those fourths subdivided into twelve equal parts. See the Plate.

Apollino.

From the bottom of the chin next the throat to the pit between the clavicles 1 fourth 9 parts.
From the pit between the clavicles to the pit at the bottom of the breast, 2 fourths 6 parts and one-half
From ditto to the pap of the right breast, 2 fourths 6 parts and one-half.
From ditto to the pap of the left breast, 2 fourths 8 parts; from pap to pap 1 head.
Whole length of the body from the pit between the clavicles to the bottom of the belly, about 3 faces.
From point to point of the os ilium next the belly, 1 head wanting 2 parts.
From the point of the right os ilium to the middle of the patella, 3 faces.
From the left ditto to the upper edge of the patella, 3 faces.
From the middle of the right patella to the sole of the foot, 3 faces.
Breadth of the face from ear to ear, 2 fourths 3 parts.
Thickness of the neck immediately under the ears, 2 fourths and half a part.
Thickness of the body in a line drawn across the paps, almost 6 fourths.
Narrowest part of the body from the lowest rib to rib, 5 fourths.
Breadth of the body where it joins the thigh, 6 fourths 8 parts.
Utmost thickness of the thigh, 3 fourths, 1 part.
Thickness of the knee across the centre of the right patella, 2 fourths nearly.
Thickest part of the calf of the leg in front, 2 fourths 2 parts.
Thinnest part of the right ancle, above the ancle bone 1 fourth 1 part and two-thirds.

Thinnest part of the right instep, below the ancles, 1 fourth 2 parts.
Thickest part of the ancle from the centre to the centre of each bone, 1 fourth 4 parts.
Thickest part of the foot, across the joint at the roots of the toes, 1 fourth 10 parts.
Utmost length of the right foot, 4 fourths 9 parts and a half.
Utmost length of the left arm from the top of the shoulder to the tip of the elbow, 6 fourths 4 parts.
From the same elbow to the joint of the wrist, nearly, 5 fourths.
From the same joint to the root of the middle finger, 1 fourth 9 parts and a half.
Thickest part of the left arm, across the insertion of the deltoid, 1 fourth 11 parts.
Thickest part of the ditto below the elbow, 1 fourth 7 parts and a half.
Thickest part of the wrist, measured from above, 1 fourth and two-thirds of a part.
From the elbow to the centre of the right arm, below where the latissimus dorsi passes, as near as can be guessed, 5 fourths and a half.
Thickest part of that arm, measured in front across the biceps, 1 fourth 10 parts.
Thickest part of the body, measured in profile on the left side, from the pit between the breasts to the back in a horizontal direction, 4 fourths 3 parts.
Thinnest part of the body on the same side, measured just above the navel, 3 fourths 9 parts.
Thickest part of the thigh in profile, measured in a horizontal direction, from the root of the penis to the glutæus, 4 fourths 6 parts.
Thinnest part, just above the knee, 2 fourths 2 parts and three-fourths.
Thickest part of the right knee, 2 fourths and 3 parts.
Thickest part of the calf of the leg, 2 fourths 3 parts and a half.
Thinnest part of the same leg, just above the instep, 1 fourth 6 parts and one-fourth.
From the centre of the inner ancle to the bottom of the heel, 1 fourth 6 parts.
From the centre of the outer ditto to ditto, 1 fourth 2 parts.

Apollo Belvidere.

From the tip of the right ear to the pit between the clavicles, 2 fourths 10 parts.
From the bottom of the left ear to the same pit, 3 fourths and half a part.
From the pit between the clavicles to the centre of the pit at the bottom of the sternum, 2 fourths 11 parts and a half.
From the pit between the clavicles to the bottom of the belly, 2 fourths 9 parts and a half.
From the point of the right ilium to the centre of the patella, 8 fourths 11 parts and a half.
From the point of the left ditto to the centre of the patella, 9 fourths 3 parts and three-fourths.
Length of the right leg from the centre of the patella to the sole of the foot, 9 fourths 1 part and one-third.
Length of the left ditto ditto, 9 fourths 5 parts and a half.
Breadth of the face from ear to ear, 2 fourths 2 parts and a third.
Breadth of the neck, taken in front like the face, 2 fourths exactly.
From the pit between the clavicles to the right pap, 3 fourths 4 parts.
From ditto to the left pap, 3 fourths 5 parts and one-fourth.
Distance across from pap to pap, 4 fourths 9 parts and three-fourths.
Breadth of the body across the paps, 6 fourths and half a part.
Narrowest part of the body, measured a little above the navel, 5 fourths 1 part and one-fourth.
Breadth of the hips, measured upon the ilium just under the obliq. descendens, 5 fourths 2 parts and a half.
Breadth from point to point of the ilium, 3 fourths 10 parts and a half.
Thickest part of the right thigh, measured in front across the head of the rectus, 2 fourths 11 parts.
Thickest part of the left ditto, 2 fourths 11 parts and a half.
Thickness of the right knee across the centre of the patella, 1 fourth 10 parts.
Thickness of the left ditto, 1 fourth 9 parts and a half.
Thickness of the calves of the legs, taken in front, 2 fourths 1 part and a half.
Small of the right leg just above the ancle, 1 fourth 2 parts and a half.
Ditto of the left leg ditto, 1 fourth 1 part.
From centre to centre of the ancle bones of each leg, 1 fourth 4 parts.
Thickness of the instep on the foot immediately under the right ancle, 1 fourth and half a part.
Length of the right foot from the point of the heel to the point of the great toe, 4 fourths 5 parts and one-fourth.
Ditto of left ditto ditto, 4 fourths 8 parts.
Breadth of the right foot on the joints at the roots of the toes, 1 fourth 6 parts and two-thirds.
Length of the right arm from the head of the deltoid to the tip of the elbow, 6 fourths 3 parts.
From the tip of the elbow to the centre of the wrist bone, 4 fourths 10 parts and two-thirds.
Thickness of the right arm, taken in front, 1 fourth 6 parts and one-third.
Ditto in profile about the middle, 2 fourths and one-third of a part.
Thickest part of the right thigh in profile as near as can be taken, 3 fourths 5 parts and three-fourths.
Thickness of the right knee ditto to the centre of the patella, 2 fourths and two-thirds of a part.
Thickness of the calf of the leg in profile, 2 fourths 2 parts.
Thickness of the small of the leg in profile, 1 fourth 5 parts and a fourth.
Total length of the Apollo, including four parts to the head, and measuring down the centre of the body, 32 fourths 2 parts.

Borghese Faun.

From the bottom of the right ear to the pit between the clavicles, 4 fourths.
Total length of the body from the pit between the clavicles to the bottom of the belly, 8 fourths 3 parts.
Length of the right thigh from the point of the ilium to the centre of the patella, 9 fourths 2 parts and one-third.
Length of the right leg from the centre of the patella to the sole of the foot, 9 fourths 6 parts.
Breadth of the shoulders just below the head of the deltoid, 8 fourths 1 part.
Breadth of the body below, measured on the obliquus descendens, 5 fourths 2 parts.
Utmost breadth of the right thigh, measured from the bottom of the testicles, 2 fourths 10 parts and a half.
Breadth of the right knee across the patella, 1 fourth 10 parts and a half.
Narrowest part immediately below the knee, 1 fourth 8 parts.
Thickest part of the calf of the right leg, 2 fourths 1 part; left leg ditto.
Narrowest part just above the ancle, 1 fourth.
Broadest part of the ancle from centre to centre of each bone, 1 fourth 4 parts and a third.
Narrowest part of the instep immediately under the ancle bone, 1 fourth.
Ditto of the left ditto, 1 fourth 1 part and a half.
Utmost length of the right foot, 4 fourths 7 parts and three fourths; ditto of the left foot, 4 fourths 7 parts.
Length of the left arm leaning from the shoulder to the point of the elbow, 6 fourths 8 parts and a third.
Ditto of the right as near as can be guessed, 6 fourths 5 parts.
From the elbow ditto to the centre of the wrist bone, 5 fourths and half a part.
Utmost thickness of the left arm across the centre of the biceps, 1 fourth 10 parts.
Breadth of the left wrist across the centre of the bones, 1 fourth 3 parts.
Thickest part of the thigh in profile from the most prominent part of the glutæus, 4 fourths 4 parts.
From the bottom of the same glutæus, measured horizontally from back to front, 3 fourths 6 parts.
Thickest part of the right knee from the head of the patella, 2 fourths 2 parts and a third.
Ditto of the calf of the right leg, 2 fourths 2 parts and a third; left leg ditto.
Thinnest part immediately under the knee, 1 fourth 11 parts and a half.
Thinnest part of the right ancle just above the instep, 1 fourth 6 parts and a half.
From the centre of the inner ancle to the sole of the foot, 1 fourth 1 part and a third.
Length of the right leg from the head of the patella to the instep, 7 fourths 8 parts and a half.
Ditto of the left from the centre of the patella, as near as can be guessed, 7 fourths 3 parts and a half.
From point to point of the ilium, 4 fourths.

Sleeping Faun (Barberini).

Distance from the right ear to the pit between the clavicles, 3 fourths.
Length of the neck from the bottom of the chin to the pit between the clavicles, 1 fourth 9 parts and a half.
From the said pit to the pit at the bottom of the sternum, 2 fourths 6 parts and a half.
Total length of the body from the said pit to the bottom of the belly, 7 fourths 1 part.
Length of the left thigh in its restored state

from the point of the ilium to the top of the patella, 9 fourths 7 parts.
From the top of the patella to the sole of the foot, 8 fourths 10 parts and a half.
Breadth of the face from ear to ear, as near as can be measured, 2 fourths 5 parts and a half.
Breadth of the neck from side to side, 2 fourths 1 part.
Ditto of the breast from pap to pap, 3 fourths 3 parts and a half.
Breadth from point to point of each ilium, 3 fourths 11 parts and one-third.
From the pit at the bottom of the sternum to the navel, 2 fourths 6 parts and a half.
Utmost thickness of the thigh across the head of the rectus, 3 fourths 2 parts and a third.
Utmost thickness of the body across the paps, 6 fourths 4 parts.
Narrowest part of ditto at the bottom of the ribs, 5 fourths 3 parts and a half.
Length of the arm over the head, from the centre of the head of the humerus, as near as can be found, to the tip of the elbow, 6 fourths.
Length of that arm below, from the tip of the elbow to the centre of the wrist, 5 fourths and one-third of a part.
Utmost thickness of the body from the most prominent part of the breast to the trapezius behind below the shoulder, measured in a right line, 4 fourths 8 parts and a half.
From the hollow part of the rectus before, a little above the navel, to the sacro-lumbalis behind, measured in a right line, 4 fourths 7 parts and a half.
Thickness of the arm from the centre of the biceps to the triceps behind, 2 fourths and half a part.

N. B. The tip of the right elbow; all the left arm below the deltoid; all the right thigh and leg, with so much of the left thigh as is between the broadest part of the rectus and its insertion at the knee, (all of which is antique, together with a part of the solæus, gasterocnemius, and peronei withoutside of the leg) and all the other part of that leg and foot, have been restored by Bernini.

Laocoon.

From the bottom of the right ear to the pit between the clavicles, 3 fourths 3 parts and one-third.
From ditto of the left ear to the said pit, 2 fourths 10 parts and a half.
From the said pit to the centre of the pit at the bottom of the sternum, 3 fourths 4 parts.
From the pit ditto to the top of the navel in a straight line, 3 fourths 4 parts.
From the top of the navel to the privities, 2 fourths 8 parts.
From the point of the ilium to the centre of the patella of the left thigh, 9 fourths 8 parts.
From the point ditto of the right thigh to the centre of the patella, 9 fourths 2 parts.
From the centre of the left patella to the instep or annular ligament, 8 fourths 2 parts.
From the said point at the instep to the bottom of the heel ditto, 1 fourth 11 parts.
Length of the right leg from the centre of the patella to the instep, 7 fourths 9 parts and a quarter.
From the said point at the instep to the bottom of the heel, 1 fourth 5 parts.

From the pit between the clavicles to either pap, 3 fourths 2 parts and three-fourths.
Length of the left arm from the head of the deltoid to the tip of the elbow, 6 fourths 7 parts and a quarter.
From the tip of the said elbow to the centre of the joint of the wrist, 5 fourths 1 part and a half.
Length of the back of the hand from the centre of the wrist to the joint of the middle finger, 1 fourth 4 parts and a third.
Length of the first joint of the middle finger, 1 fourth 1 part.
Thickness of the neck in front, about the middle, 2 fourths 3 parts.
Distance across from pap to pap, 4 fourths 2 parts and two-thirds.
Breadth of the body measured horizontally across the nipples, 6 fourths 5 parts and a half.
Breadth of ditto measured horizontally at the narrowest part across the bottom of the ribs, 5 fourths.
Breadth across on the ilium immediately under the obliquus descendens, 5 fourths 4 parts.
Thickness of the left thigh measured across the centre of the rectus, 3 fourths 3 parts and one-third.
Thickness of the knee measured across the centre of the patella, 1 fourth 11 parts and a half.
Thickness of the right ditto, 1 fourth 11 parts and a half.
Thickness of the calf of either leg, 2 fourths 2 parts.
Thickness of the smallest part just above the ancle, 1 fourth and half a part.
From centre to centre of the left ancle bone, 1 fourth 5 parts; right, ditto.
Narrowest part of the instep just under the ancles, 1 fourth and two-thirds of a part.
Breadth of the foot from the centre of the joint at the root of the great toe to ditto of the little one, 1 fourth 11 parts and one-third.
Thickest part of the left arm measured across the centre of the biceps, 2 fourths 2 parts and one-third.
Ditto of the said arm measured on the supinator just below the elbow, 1 fourth 9 parts and a half.
Breadth across the wrist measured from the centre of the joint, 1 fourth 3 parts.
Breadth of the hand measured upon the joint at the roots of the fingers, 1 fourth 10 parts and two-thirds.
Thickness of the body in profile measured from the centre of the pectoral muscle to the most prominent part of the trapezius behind, 4 fourths 9 parts.
Thinnest part of the body in profile measured just above the navel, 3 fourths 6 parts and a half.
Thickness of the knee from the head of the gasterocnemius to the centre of the patella, 2 fourths 6 parts and a half.
Thickest part of the calf of the right leg in profile, 2 fourths 4 parts.
Thinnest part of the small of the left leg in profile, 1 fourth 6 parts.
Length of the left foot from the heel to the top of the great toe, 4 fourths 8 parts.
Total length of the figure of the Laocoon, allowing 4 fourths for the head, and measuring from the bottom of the chin to the pit between the clavicles, and from thence, following with the utmost exactness the line of the centre of the body, then measuring on the centre of the left thigh (after having found the point by laying a rule across from the bottom of the belly parallel with the two points of the ilium), and so down the centre of the patella, and upon the leg to the sole of the foot, 34 fourths.

Laocoon's elder son.

From the bottom of the left ear to the pit between the clavicles, 2 fourths 11 parts.
From ditto of the right ear to the said pit, 2 fourths 6 parts and a half.
From the said pit to the centre of the pit at the bottom of the sternum, 2 fourths 7 parts and a half.
From the centre of the said pit to the centre of the navel, 2 fourths 7 parts.
From the centre of the navel to the privities, 2 fourths 3 parts and one-third.
From the point of the right ilium to the centre of the patella, 8 fourths 7 parts and a half.
From the centre of the patella to the instep, 8 fourths 1 part.
From the said instep to the bottom of the heel, 1 fourth 8 parts and one-third.
From the centre between the clavicles to either pap, 2 fourths 10 parts and three-fourths.
Distance from pap to pap, 4 fourths 5 parts and one-third.
Ditto from point to point of the ilium, 3 fourths 4 parts.
Length of the left arm measured from the head of the humerus, as near as can be guessed, to the tip of the elbow, 5 fourths 8 parts and two-thirds.
From the tip of the elbow to the centre of the wrist bone, 4 fourths 7 parts and one-third.
Broadest part of the body measured across the paps, 6 fourths 4 parts.
Narrowest part of ditto measured across the bottom of the ribs, 5 fourths 3 parts.
Breadth of the body measured upon the ilium immediately under the obliquus descendens, 5 fourths 7 parts and a half.
Thickest part of the right thigh in front, across the centre of the rectus, 2 fourths 7 parts and a half.
Thickness of the knee across the centre of the patella, 1 fourth 11 parts and one-third.
Thickest part of the calf of the leg, 2 fourths 3 parts.
Thickness of the small of ditto just above the ancle, 1 fourth 1 part and a half.
Thickness of the ancle from the centre of each bone, 1 fourth 4 parts and a quarter.
Broadest part of the right foot across the joints at the roots of the toes, 1 fourth 8 parts.
Thickness of the upper arm in profile across the middle of the biceps, 1 fourth 11 parts and a half.
Ditto of the lower arm just below the elbow, ditto, 1 fourth 6 parts.
Thickness of the right thigh in profile, 3 fourths 4 parts and three-fourths.
Ditto of the knee ditto from the centre of the patella, 2 fourths 6 parts.
Thickness of the calf of the leg ditto, 2 fourths 4 parts.

Thickness just above the ancle ditto, 1 fourth 5 parts.

Thickness of the body in profile from the most prominent part of the pectoral muscle to the trapezius behind, 4 fourths 3 parts and a half.

Narrowest part of ditto measured a little above the navel, 3 fourths 3 parts.

Total length of the figure measured down the centre, allowing 4 fourths to the head, and observing the same method as with the foregoing statue of the father, 30 fourths exact.

Younger son of Laocoon.

From the tip of the right ear to the pit between the clavicles, 2 fourths 8 parts.

From the said pit to the pit at the bottom of the sternum, 2 fourths 8 parts.

From ditto to the right pap, 2 fourths 8 parts.

From the pit between the clavicles to the bottom of the belly, 8 fourths.

From the point of the right ilium to the top of the patella, 7 fourths 9 parts.

From the top of the patella ditto to the sole of the foot, 8 fourths 7 parts.

Length of the right foot from the heel to the great toe, 4 fourths 2 parts and one-third.

Breadth of the narrowest part of the body in front at the bottom of the ribs, 4 fourths 2 parts.

Thickness of the thigh measured across the centre of the rectus, 3 fourths and half a part.

Thickness of the calf of the leg ditto, 2 fourths 3 parts.

Thickness of the smallest part of the leg just above the ancle, 1 fourth 2 parts.

From centre to centre of each ancle bone 1 fourth 4 parts.

Thickness of the body from the most prominent part of the pectoral muscle to the trapezius behind, 4 fourths.

Narrowest part of the body just above the navel, 2 fourths 9 parts and two-thirds.

Thickness from the most prominent part of the glutæus, to the point of the ilium, 3 fourths 8 parts and a half.

Thickest part of the thigh in profile about the centre of the rectus, 2 fourths 10 parts and two-thirds.

Thickness of the calf of the leg, 2 fourths 2 parts.

Thickness of the smallest part in profile, 1 fourth 5 parts.

Length of the arm on the body from the head of the deltoid to the tip of the elbow, 5 fourths 6 parts and two-thirds.

From the tip of the elbow to the centre of the wrist bone, 4 fourths 5 parts and one-third.

From the joint of the wrist upon the extensores communes to the joint of the middle finger, 2 fourths 9 parts.

Meleager.

From the left ear to the pit between the clavicles, 2 fourths 10 parts and a half; from the right ditto, 2 fourths 9 parts and a half.

From the pit between the clavicles to the bottom of the belly, 9 fourths.

From ditto to the centre of the pit at the bottom of the sternum, 3 fourths.

From ditto to the pap on the right breast, 4 fourths 1 part and a half.

Length of the right thigh from the point of the ilium to the top of the patella, 9 fourths.

From the top of the patella to the sole of the foot ditto, 9 fourths 3 parts.

Distance from pap to pap, 4 fourths 2 parts.

Broadest part of the body measured across the paps, 8 fourths 9 parts and two-thirds.

Narrowest part of ditto measured at the bottom of the ribs, 5 fourths 5 parts.

Breadth of the hips measured on the ilium immediately under the obliquus descendens, 5 fourths 7 parts and a half.

Thickest part of the thigh measured in front, 2 fourths 10 parts and one-third.

Thickness of the right knee across the centre of the patella, 1 fourth 10 parts and a half.

Thickest part of the calf of the leg, 2 fourths 1 part and one-third.

Thickness of the small of the leg ditto just above the ancle, 1 fourth.

From centre to centre of each ancle bone, 1 fourth 5 parts.

Length of the right foot from the heel to the tip of the toe, 4 fourths and 9 parts.

Broadest part of the said foot from the joint at the root of the great toe to ditto of the little toe, 1 fourth 9 parts.

Breadth of the face from ear to ear in front, 2 fourths 3 parts.

Ditto of the neck ditto in front about the middle, 2 fourths and half a part.

Length of the arm from the head of the deltoid to the tip of the elbow, 6 fourths 11 parts and one-third.

Thickest part of the arm measured in front across the biceps, 1 fourth 7 parts and a half.

Thickness of the arm in profile from the biceps to the triceps behind, 2 fourths 1 part and three-fourths.

Ditto of the body measured from the most prominent part of the pectoral muscle to the trapezius, 4 fourths 6 parts and one-third.

Narrowest part of the body in profile ditto, just above the navel, 3 fourths 7 parts and one-third.

Thickest part of the thigh on the rectus just under the glutæus, 3 fourths 4 parts and one-third.

Thickness of the knee in profile on the centre of the patella, 2 fourths 2 parts.

Thickest part of the calf of the leg in profile, 2 fourths 2 parts and three-fourths.

Smallest of ditto, 1 fourth 4 parts.

Breadth from point to point of the ilium, 3 fourths 9 parts and two-thirds.

Total length of the figure, allowing 4 fourths to the head, and measuring down the line of the centre of the body, then laying a line parallel with the points of the ilium, and measuring down the middle of the thigh to the sole of the right foot, 31 fourths 4 parts.

Antinous.

From the bottom of the left ear to the pit between the clavicles, 2 fourths 9 parts.

From the pit between the clavicles to the pit at the bottom of the breast, 2 fourths 10 parts and two-thirds.

From ditto to either pap, 3 fourths 4 parts.

From ditto to the bottom of the belly, 9 fourths.

From the point of the ilium to the centre of the patella, 9 fourths.

From ditto to the sole of the foot, 9 fourths.

From pap to pap, 4 fourths 10 parts.

From point to point of the ilium, 3 fourths 10 parts and one-third.

Breadth of the face from ear to ear, 2 fourths 3 parts and two-thirds.

Thickness of the neck about the middle, 2 fourths 1 part and a half.

Broadest part of the shoulders from deltoid to deltoid, 8 fourths 9 parts and a half.

Narrowest part of the body at the bottom of the ribs, 5 fourths 1 part.

Breadth measured on the ilium immediately under the obliquus descendens, 5 fourths 4 parts and a half.

Ditto of the thickest part of the left thigh across the rectus, 3 fourths 1 part.

Ditto of the right ditto, 2 fourths 11 parts.

Thickness of the left knee across the centre of the patella, 1 fourth 11 parts.

Ditto of the right ditto, 2 fourths.

Thickness of the right leg at the thickest part, 2 fourths 3 parts.

From centre to centre of the ancle bones, 1 fourth 4 parts and one-third.

The foot is not antique.

Length from the head of the deltoid to the centre of the right elbow, 6 fourths 9 parts and a half.

From ditto to the centre of the wrist bone, 4 fourths 6 parts and a half.

From the centre of the wrist bone to the joint of the little finger, 1 fourth 6 parts and a half.

Breadth of the body in profile from the shoulder to the most prominent breast, 4 fourths 10 parts and a half.

Narrowest part of the body ditto at the bottom of the ribs, 3 fourths 4 parts and three-fourths.

Thickness from the most prominent part of the glutæus to the head of the rectus ditto, 4 fourths 1 part.

Thickest part of the thigh about the middle of the rectus, 3 fourths 5 parts.

Thickest part of the knee ditto, 2 fourths 3 parts.

Thickness of the arm ditto about the middle of the breasts, 2 fourths 2 parts and one-third.

Germanicus.

From the bottom of the chin to the pit between the clavicles, 1 fourth and two-thirds of a part.

From the tip of each ear to the said pit, 2 fourths 7 parts and a third.

From the pit between the clavicles to the bottom of the belly, 9 fourths exactly.

From the point of the ileum to the centre of the patella of the left leg, 9 fourths 3 parts.

From the centre of the patella to the sole of the foot of ditto, 7 fourths 9 parts and a third.

From the pit between the clavicles to the pit at the bottom of the sternum, 3 fourths 3 parts and a half.

From ditto to the right and left pap of the breast, 3 fourths 3 parts and a half.

From pap to pap, 4 fourths 5 parts and a half.

From point to point of each ilium, (in their oblique situation) 3 fourths 10 parts.

From ear to ear measured across the face, 2 fourths 5 parts and a half.
Utmost thickness of the neck in front, 2 fourths 1 part.
From the pit between the clavicles to the left shoulder measured horizontally, 4 fourths 4 parts.
From the great trochanter of the left thigh to the most prominent part of the right thigh measured horizontally, 5 fourths 9 parts and one-half.
Thickest part of the right thigh measured horizontally across the middle of the rectus, 3 fourths.
Ditto of the left ditto continuing the same horizontal line, 2 fourths 8 parts.
Right knee across the centre of the patella, 1 fourth 10 parts; left ditto, ditto.
Thickest part of the calf of the right leg, 2 fourths 1 part and a half; ditto of the left, 2 fourths and a third of a part.
Thinnest part of the ancle of the left leg, 1 fourth 1 part and a fourth; right, ditto.
Thickest part of the ancles from the centre of bone to bone, 1 fourth 2 parts and three-fourths.
Thickest part of the right foot from the joint at the root of the great toe, 1 fourth 9 parts.
Ditto, ditto of the left foot, 1 fourth 8 parts.
From the head of the deltoid muscle to the tip of the right elbow measured within, in front, 6 fourths 2 parts.
From the tip of the elbow to the centre of the ulna at the right wrist, 4 fourths 4 parts and a half.
From the head of the deltoid to the left elbow, 5 fourths 9 parts and a half.
Thickest part of the body from the most prominent part of the pectoral muscle before, to the most prominent part of the scapula, taken horizontally in profile, 4 fourths 10 parts and a half.
Narrowest part of the body measured just above the navel, 3 fourths 6 parts.
From the hollow of the thigh at the head of the rectus before, to the most prominent part of the glutæus behind, 4 fourths 2 parts.
Thickest part of the right thigh measured below the glutæus, 3 fourths 5 parts and a half.
Thickness of the right knee in profile from the centre of the patella to the hollow behind, 2 fourths 2 parts and a half.
Thickest part of the calf of the right leg in profile, 2 fourths 2 parts; ditto above the ancle, 1 fourth 5 parts.
Length of the right foot, 4 fourths 4 parts and three-fourths.
Thickest part of the right arm from the biceps to the triceps, 1 fourth 11 parts and one-third.
Broadest part of the wrist from bone to bone, 1 fourth 2 parts.
Thickest part of the neck taken in profile, 2 fourths.

Far the greatest number of the so much admired Grecian statues lay, for a long series of years, buried under the ruins of Rome. The following is a brief account of the

Discovery of several of the most celebrated statues, or groups, in various parts of Rome.

I. The equestrian statue of M. Aurelius was found on the Cælian hill, near the present church of St. John Lateran, in the pontificate of Sixtus IV. (1471 to 1484) who placed it in that area. About the year 1540 it was removed to the capitol, under the direction of Michel Angelo.

II. The torso of Hercules in the Vatican, was found in the Campo de Fiori, in the time of Julius II.

III. The group of the Laocoon was discovered in the vineyard of Gualtieri, near the baths of Titus, by Felix de Fredis, in 1512, as recorded on his tomb in the church of Ara Cœli.

IV. In the reign of Leo X: the Antinous, or Mercury according to Visconti, was found on the Esquiline hill, near the church of St. Martin.

V. Leo was likewise successful in recovering from oblivion the Venus called de Medicis. It was found in the portico of Octavia, built by Augustus, near the Theatre of Marcellus, in the modern Pescheria. Removed to the gallery at Florence by Cosmo III. in 1676.

VI. The colossal Pompey of the Spada palace, was found during the pontificate of Julius III. (1550 to 1555) near the church of St. Lorenzo in Damasco.

VII. The Hercules, and the groupe of Dirce, Zethus, and Amphion, called "Il toro," now at Naples, were dug up in the baths of Caracalla, and placed in the Farnese palace, about the middle of the sixteenth century.

VIII. The Apollo Belvidere, and the Gladiator of the Villa Borghese, were taken from under the ruins of the palace and gardens of Nero at Antium, 40 miles from Rome, when the Casino was made there by cardinal Borghese, during the reign of Paul V. (1605 to 1621).

IX. Soon afterward, the sleeping Faun, now in the Barberini palace, was found near the mausoleum of Hadrian.

X. The Mirmillo Expirans, or Dying Gladiator of the capitol, was dug up in the gardens of Sallust, on the Pincian hill, now the Villa Borghese: it was purchased by Benedict the 14th, of cardinal Lodovisi.

XI. The small Harpocrates and the Venus of the Capitol were found at Tivoli in the same reign.

XII. The Meleager, once in the Picchini collection, now in the Vatican, was found near the church of St. Bibiena.

STATUTE, in its general sense, signifies a law, ordinance, decree, &c. Statute, in our laws and customs, more immediately signifies an act of parliament made by the three estates of the realm; and such statutes are either public, of which the courts at Westminster must take notice, without pleading them; or they are special and private, which last must be pleaded. It is held, that a public statute, made in affirmation of the common law, extends to all times after the making thereof, although it mentions only a remedy for the present; and where a thing is given or granted by statute, all necessary incidents are at the same time granted with it. The most natural exposition of a statute is, to construe one part by another of the same statute, because that best expresses the intent of the makers; also statutes, in general, ought to be expounded in suppression of the mischief, and for the advancement of the remedy designed by any statute, yet so that no innocent person may suffer or receive any damage thereby. It is held, that statutes will continue in force, though the records of them are destroyed. &c. But if a statute is against reason, or impossible to be performed, the same is void of course.

When a statute is repealed, all acts done under it, while it was in force, are good; but if it is declared null, all these are void. Jenk. 233., pl. 6.

Where a statute, before perpetual, is continued by an affirmative statute, for a time, this does not amount to a repeal of it at the end of that time. Lord Raym. 397.

Where two acts contradictory to each other, are passed in the same session, the latter only shall take effect. 6 Mod. 287.

STATUTE MERCHANT, is a bond of record, acknowledged before one of the clerks of the statute merchant, and lord mayor of the city of London, or two merchants of the said city, for that purpose assigned, or before the mayor or warden of the town, or other discreet men for that purpose assigned. This recognizance is to be entered on a roll, which must be double, one part to remain with the mayor, and the other with a clerk, who shall write with his own hand a bill obligatory, to which a seal of the king for that purpose appointed, shall be affixed, together with the seal of the debtor. 2 Bac. Abr. 331.

The design of this security was to promote and encourage trade, by providing a sure and speedy remedy for merchant-strangers, as well as natives, to recover their debts at the day assigned for payment.

But though the statute-merchant seems first to be introduced, and wholly calculated, for the ease and benefit of merchants, as the name itself imports; yet they were not long engrossed by them: for other men finding from their own observation, that they have much of the same nature with judgments in Westminster-hall, but obtained with less trouble and expence, out of regard to their own interest and quiet, easily fell into this way of contracting, and by degrees it came to be improved into a common assurance, as we find it at this day. Winch. 83. See INSURANCE.

STATUTE STAPLE, is a bond of record, acknowledged before the mayor of the staple, in the presence of all or one of the constables. But now statute staple, as well as statute merchant, are in a great measure become obsolete.

STATUTES, or STATUTES SESSIONS, otherwise called petit sessions, are a meeting in every hundred, of all the shires in England, where by custom they have been used, whereto the constables and others, both householders and servants, repair for the debating of differences between masters and servants, the rating of servants' wages, and bestowing such people in service, as being fit to serve, either refuse to seek or get masters. Stat. 5 Eliz. c. 5.

STAVE, in music, the five horizontal and parallel lines on and between which the notes are placed.

Guido, the great improver of the modern music, is said by some to have first used the stave; but others give an earlier date to its introduction. Kircher affirms, that in the jesuit's library at Messina he found a Greek manuscript of hymns more than seven hundred years old, in which some of the music was written on staves of eight lines, marked at the beginning with eight Greek letters; the notes, or rather points, were on the lines, but no use was made of the spaces. This, however, at most, only deprives Guido of the original invention of the stave, and still leaves him the credit of its great improvement by reducing it to five lines, and employing both lines and spaces.

STAUROLITE, in mineralogy. This stone has been found at Andreasberg in the Hartz. It is crystallized, and the form of its crystals has induced mineralogists to give it the name of cross-stone. Its crystals are two four-sided flattened prisms, terminated by four-sided pyramids, intersecting each other at right angles; the plane of intersection passing longitudinally through the prism. Sometimes these prisms occur solitary. Primitive form, an octahedron with isosceles triangular faces. The faces of the crystals striated longitudinally.

Its texture is foliated. Its lustre glassy. Brittle. Specific gravity 2.33 to 2.36. Colour milk-white. When heated slowly, it loses 0.15 or 0.16 parts of its weight, and falls into powder. It effervesces with borax and microcosmic salt, and is reduced to a greenish opaque mass. With soda it melts into a frothy white enamel. When its powder is thrown on a hot coal, it emits a greenish-yellow light.

A specimen analysed by Westrum was composed of

44 silica
20 alumina
20 barytes
16 water

100.

Klaproth found the same ingredients, and nearly in the same proportions.

A variety of staurolite has been found only once, which has the following properties:

Its lustre is pearly, 2. Specific gravity 2.361. Colour brownish-grey. With soda it melts into a purplish and yellowish frothy enamel. It is composed, according to Westrum, of

47.5 silica
12.0 alumina
20.0 barytes
16.0 water
4.5 oxides of iron and manganese

100.0.

STAY, in the sea-language, a strong rope fastened to the top of one mast, and to the foot of that next before it, towards the prow, serving to keep it firm, and prevent its falling aftwards or towards the poop. All masts, top-masts, and flag-staves, have their stays, except the sprit-sail top-masts. That of the main-mast is called the main-stay. The main-mast, fore-mast, and those belonging to them, have also back-stays to prevent their pitching forwards or overboard.

STEALING, the fraudulent taking away of another man's goods, with an intent to steal them, against, or without, the will of him whose goods they are. See BURGLARY, LARCENY, and ROBBERY.

STEAM. See WATER.

STEAM-ENGINE. See ENGINE, *steam*.

STEATITES, in mineralogy, is usually amorphous, but sometimes crystallized in six-sided prisms. Its texture is commonly earthy: specific gravity 2.61 to 2.79; feels greasy; seldom adheres to the tongue: colour white or grey, with a tint of other colours; the foliated green. Does not melt per se before the blowpipe. There are three varieties: specimens analyzed by Klaproth and Chenevix, contained as follows;

By Klaproth.	By Chenevix.
59.5 silica	60.00 silica
30.5 magnesia	28.50 magnesia
2.5 iron	3.00 alumina
5.5 water	2.50 lime
	2.25 iron
98.0	97.25.

STEEL, a carburet of iron, or that metal combined with a small portion of carbon. See IRON.

STEERAGE, on board a ship, that part of the ship next below the quarter-deck, before the bulk-head of the great cabin, where the steersman stands in most ships of war. See the next article.

STEERING, in navigation, the directing of a vessel from one place to another by means of the helm and rudder. He is held the best steersman who causes the least motion in putting the helm over to and again, and who best keeps the ship from making yaws, that is, from running in and out. There are three methods of steering: 1. By any mark on the land, so as to keep the ship even by it. 2. By the compass, which is by keeping the ship's head on such a rhumb or point of the compass as best leads to port. 3. To steer as one is bidden or conned, which, in a great ship, is the duty of him that is taking his turn at the helm.

STELLARIA, *stichwort*, a genus of plants belonging to the class of decandria, and order of trigynia, and in the natural system arranged under the 22d order, caryophylleæ. The calyx is pentaphyllous and spreading. There are five petals, each divided into two segments. The capsule is oval, unilocular, and polyspermous. There are 17 species; three of these are British plants. 1. Nemorum, broad-leaved stichwort. 2. Holostea, greater stichwort; it is common in woods and hedges. 3. Graminea, less stichwort. The stem is near a foot high. It is frequent in dry pastures.

STELLATE. See BOTANY.

STELLERA, *German groundsel*, a genus of plants belonging to the class of octandria, and order of monogynia, and in the natural system arranged under the 31st order, vepreculæ. There is no calyx; the corolla is quadrifid. The stamina are very short; there is only one seed, which is black. The species are two in number, passerina and chamaejasme.

STEM. See BOTANY.

STEM *of a ship*, that main piece of timber which comes bending from the keel below, where it is scarfed, as they call it, that is, pieced in; and rises compassing right before the forecastle. This stem it is which guides the rake of the ship, and all the butt-ends of the planks are fixed into it. This, in the section of a first-rate ship, is called the main stem. See SHIP-BUILDING.

STEMMATA, in the history of insects, are three smooth hemispheric dots, placed generally on the top of the head, as in most of the hymenoptera and other classes.

STEMODIA, a genus of plants belonging to the class of didynamia, and order of angiospermia, and in the natural system ranging under the 40th order, personatæ. The calyx is quinquepartite; the corolla bilabiated; there are four stamina; each of the filaments is bifid, and they have two antheræ. The capsule is bilocular. There are four species, herbs of the East and West Indies.

STENOGRAPHY. The art of stenography, or short-hand writing, was known and practised by most of the antient civilized nations. The Egyptians, who were distinguished for learning at an early period, at first expressed their words by a delineation of figures called hieroglyphics. A more concise mode of writing seems to have been afterwards introduced, in which only a part of the symbol or picture was drawn. This answered the purpose of short-hand in some degree. After them the Hebrews, the Greeks, and the Romans, adopted different methods of abbreviating their words and sentences, suited to their respective languages. The initials, the finals, or radicals, often served for whole words; and various combinations of these sometimes formed a sentence. Arbitrary marks were likewise employed to determine the meaning, and to assist legibility; and it seems probable that every writer, and every author of antiquity, had some peculiar method of abbreviation, calculated to facilitate expression of his own sentiments, and intelligible only to himself.

It is also probable, that some might by these means take down the heads of a discourse or oration; but few, very few, it is presumed, could have followed a speaker through all the meanders of rhetoric, and noted with precision every syllable, as it dropt from his mouth, in a manner legible even to themselves. To arrive at perfection in the art was reserved for more modern times, and is still an acquisition by no means general.

In every language of Europe, till about the close of the 16th century, the Roman plan of abbreviating (viz. substituting the initials or radicals, with the help of arbitrary characters for words), appears to have been employed. Till then no regular alphabet had been invented expressly for stenography, when an English gentleman of the name of Willis invented and published one; since which we have had a multitude of others by Mason, Gurney, Byrom, Palmer, &c. &c. The following is extracted from Dr. Mavor's treatise on the art, which has met with general approbation:

Rules for Orthography in SHORT HAND.

1. All quiescent consonants in words are to be dropped; and the orthography to be directed only by the pronunciation: which, being known to all, will render this art attainable by those who cannot spell with precision in long hand. 2. When the absence of consonants, not entirely dormant, can be easily known, they may often be omitted without the least obscurity. 3. Two, or sometimes more consonants, may, to promote greater expedition, be exchanged for a single one of nearly similar sound; and no ambiguity as to the meaning ensue. 4. When two consonants of the same kind or same

sound come together, without any vowel between them, only one is to be expressed; but if a vowel or vowels intervene, both are to be written: only observe, if they are perpendicular, horizontal, or oblique lines, they must only be drawn a size longer than usual; and characters with loops must have the size of their heads doubled. See Plate.

Might is to be written *mit*, fight *fit*, machine, *mashin*, enough *enuf*, laugh *laf*, prophet *profet*, physics *fisiks*, through *thro'*, foreign *foren*, sovereign *soveren*, psalm *sam*, receipt *reset*, write *rite*, wright *rit*, island *iland*, knavery, *navery*, temptation *temtation*, knife *nife*, stick *stik*, thigh *thi*, honour *onour*, indictment *inditement*, acquaint *aquaint*, chaos *kaos*, &c.

Strength *strenth*, length *lenth*, friendship *frenship*, connect *conek*, commandment, *comanment*, conjunct *conjunt*, humble *humle*, lumber *lumer*, slumber *slumer*, number *numer*, exemplary *exemlary*, &c.

Rocks *rox*, acts, *aks* or *ax*, facts *faks* or *fax*, districts *distriks*, or *distrix*, affects *afeks* or *afex*, afflicts *afliks* or *aflix*, conquer, *konkr*, &c.

Letter *leter*, little *litle*, command *comand*, error *eror*, terror *teror*, &c. But in *remember*, *moment*, *sister*, and such like words, where two consonants of the same name have an intervening vowel, both of them must be written.

These four rules, with their examples, being carefully considered by the learner, will leave him in no doubt concerning the disposition and management of the consonants in this scheme of short-writing; we shall therefore proceed to lay down rules for the application of the vowels with ease and expedition.

1. Vowels, being only simple articulate sounds, though they are the connectives of consonants, and employed in every word and every syllable, are not necessary to be inserted in the middle of words; because the consonants, if fully pronounced, with the assistance of connection, will always discover the meaning of a word, and make the writing perfectly legible.

2. If a vowel is not strongly accented in the incipient syllable of a word, or if it is mute in the final, it is likewise to be omitted; because the sound of the incipient vowel is often implied in that of the first consonant, which will consequently supply its place.

3. But if the vowel constitutes the first or last syllable of a word, or is strongly accented at its beginning or end, that vowel is continually to be written.

4. If a word begins or ends with two or more vowels, though separated, or when there is a coalition of vowels, as in diphthongs and triphthongs, only one of them is to be expressed, which must be that which agrees best with the pronunciation.

5. In monosyllables, if they begin or end with a vowel, it is always to be inserted, unless the vowel is *e* mute at the end of a word.

Such are the general principles of this art; in vindication and support of which it will be needless to offer any arguments, when it is considered that brevity and expedition are the chief objects, if consistent with legibility; and the subsequent specimens in the orthography recommended, will, we hope, be sufficient to show that there is no real deficiency in the last-mentioned particular.

He who md us mst be etrnl, grt, nd mnptnt. It is ur dty, as rtnl bngs, to srv, lv, nd oby hm. A mn tht wd avd blm, shd be srkmspk in al hs axns, nd ndvr wth al hs mt to pls evry bdy. But al prd of ths srt is fly, nd evr to be avdd.

As the whole of this art depends upon a regular method and a simple alphabet, we have not only endeavoured to establish the former on satisfactory principles, but have been careful to appropriate, according to the comparative frequency of their occurrence, such characters for the letters as, after repeated trials and alterations, were conceived to be the best adapted for dispatch.

The short-hand alphabet consists of 18 distinct characters (viz. two for the vowels and the rest for the consonants) taken from lines and semicircular curves; the formation and application of which we shall now explain, beginning with the vowels.

For the three first vowels, *a*, *e*, and *i*, a comma is appropriated in different positions; and for the other three, *o*, *u*, and *y*, a point. The comma and point, when applied to *a* and *o*, is to be placed, as in the Plate, at the top of the next character; when for *e* and *u*, opposite to the middle; and when for *i* and *y*, at the bottom.

This arrangement of the vowels is the most simple and distinct that can be easily imagined. Places at the top, the middle, and the bottom of characters, which make three different positions, are as easily distinguished from one another as any three separate characters could be; and a comma is made with the same facility as a point.

Simple lines may be drawn four different ways; perpendicular, horizontal, and with an angle of about forty-five degrees to the right and left. An ascending oblique line to the right, which will be perfectly distinct from the rest when joined to any other character, may likewise be admitted. These characters being the simplest in nature, are assigned to those five consonants which most frequently occur, viz. *l*, *r*, *t*, *c* hard or *k*, and *c* soft or *s*.

Every circle may be divided with a perpendicular and horizontal line, so as to form likewise four distinct characters. These being the next to lines in the simplicity of their formation, we have appropriated them for *b*, *d*, *n*, and *m*.

The characters expressing nine of the consonants are all perfectly distinct from one another; eight only remain which are needful, viz. *f*, *g*, or *j*, *h*, *p*, *q*, *v*, *w*, and *x*, to find characters for which we must have recourse to mixed curves and lines. The characters which we have adopted are the simplest in nature after those already applied, admit of the easiest joining, and tend to preserve lineality and beauty in the writing.

It must be observed that we have no character for *c* when it has a hard sound, as in *castle*; or soft, as in *city*; for it naturally takes the sound of *k* or *s*, which in all cases will be sufficient to supply its place.

R likewise is represented by the same character as *l*; only with this difference, *r* is written with such an ascending stroke and *l* with a descending; which is always to be known from the manner of its union with the following character; but in a few monosyllables, where *r* is the only consonant in the word, and consequently stands alone, it is to be made as is shown in the alphabet for distinction's sake.

Z, as it is a letter seldom employed in the English language, and only a coarser and harder expression of *s*, must be supplied by *s* whenever it occurs; as for *Zedekiah*, write *Sedekiah*, &c.

The prepositions and terminations in this scheme are so simple, that the greatest benefit may be reaped from them, and very little trouble required to attain them; as the incipient letter or the incipient consonant of all the prepositions, and of several of the terminations, is used to express the whole. But although in the Plate sufficient specimens are given of the manner of their application, that the learner of less ingenuity or more slow perception may have every assistance, we have subjoined the following directions:

1. The preposition is always to be written without joining, yet so near as plainly to show what word it belongs to; and the best way is to observe the same order as if the whole was to be connected.

2. A preposition, though the same letters that constitute it may be met with in the middle or end of a word, is never to be used, because it would expose it to obscurity.

3. Observe that the preposition omni is expressed by the vowel *o* in its proper position; and for *anti*, *anta*, *ante*, by the vowel *a*, which the radical part of the word will easily distinguish from being only simple vowels.

The first rule for the prepositions is (allowing such exceptions as may be seen in the Plate) to be observed for the terminations; and also the second *mutatis mutandis*, except that whenever *sis*, *sus*, *sys*, *cious*, *tious*, and *ces*, occur, they are to be expressed as directed in the fourth rule for the consonants, whether in the beginning, middle, or end of words.

4. The terminative character for *tion*, *sion*, *cion*, *cian*, *tian*, is to be expressed by a small circle joined to the nearest letter, and turned to the right; and the plurals, *tions*, *sions*, *cions*, *cians*, *tians*, *tience*, by a dot on the same side.

5. The terminative character for *ing* is to be expressed likewise by a small circle, but drawn to the left hand; and its plural *ings* by a dot.

6. The plural sign *s* is to be added to the terminative characters when necessary.

7. The separated terminations are never to be used but in polysyllables, or words of more syllables than one.

These directions duly observed, together with a proper attention to the engraved plate, and a regard to what has gone before in this art, will point out a method as concise and elegant as can be desired, for expressing the most frequent and longest prepositions and terminations in the English language. If it should be thought necessary to increase their number by the addition of others, it will be an easy matter for any one of the least discernment to do so, by proceeding on the principles before laid down.

STEP *of the mast and capstan*, in a ship, is that piece of timber whereon the masts or capstans stand at bottom.

STEPHANIUM, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 47th order, stellatæ. The calyx is monophyllous, turbinated, and quinquepartite; the corolla is monopetalous, funnel-shaped, having its tubes curved and ventricose; the pericarpium is a bilocular berry, containing two seeds, flattened on one side, and round on the other. This genus is nearly allied to that of psychotria. There is only one species, viz. guianense, a native of the warmer parts of America.

STERBEEKIA, a genus of the class and order polyandria monogynia; the calyx is three or five valved; corolla three or five petalled; caps. corticose; seeds intricate; nothing in pulp. There is one species, a shrub of Guiana.

STERCULIA, a genus of plants belonging to the class dodecandria, and order of monogynia, and in the natural system ranking under the 38th order, tricocceæ. The calyx is quinquepartite; there is no corolla; the nect. is bell-shaped; germ pedicelled; and the capsule is quinquelocular, and many-seeded. There are eight species, all foreign plants.

STEREOGRAPHIC PROJECTION. See PROJECTION.

STEREOGRAPHY, the art of drawing the forms and figures of the solids upon a plane.

STEREOMETRY, that part of geometry which teaches how to measure solid bodies, that is, to find the solidity or solid content of bodies, as globes, cylinders, cubes, vessels, ships, &c.

STEREOTYPE PRINTING. This is said to be an improvement in the art, and was introduced into this country by Mr. Ged, of Edinburgh, who, instead of types or single letters, formed a plate for each separate page, from which the work is printed. With the first inventor it did not succeed; though the pretensions of Ged, as an inventor, may be disputed, for precisely the same principle was adopted many hundred years ago by the Chinese and Japanese, who first practised the art of printing by means of wooden blocks. The mode of stereotype printing is, first to set up a page, for instance, in the common way, and when it is rendered perfectly correct, a cast is taken from it, and in this cast the metal for the stereotype plate is poured. This method of printing has lately been brought into practice by earl Stanhope, who seems to have overcome all difficulties, and to have rendered the art as perfect as can be expected. His lordship intends to make the invention public.

STERLING, a term frequent in British commerce. A pound, shilling, or penny, sterling, signifies as much as a pound, shilling, or penny, of lawful money of Great Britain, as settled by authority.

STERN *of a ship*, usually denotes all the hindermost part of her, but properly it is only the outmost part abaft.

STERN-FAST, denotes some fastenings of ropes, &c. behind the stern of a ship, to which a cable or hawser may be brought or fixed, in order to hold her stern to a wharf, &c.

STERN-POST, a great timber let into the keel at the stern of a ship, somewhat sloping, into which are fastened the afterplanks; and on this post, by its pintle and gudgeons, hangs the rudder.

STERNA, *the tern*, a genus of birds of the order anseres. The marks of this genus are a straight, slender, pointed bill, linear nostrils, a slender and sharp tongue, very long wings, a small back toe, and a forked tail. There are 25 species, according to Dr. Latham; the caspia, cayana, surinamensis, fuliginosa, africana, stolida, philippina, simplex, nilotica, boysii, striata, vittata, sadicea, pilcata, hirundo, panaya, cinerea, alba, minuta, sinensis, australis, metopoleucos, fissipes, nigra, and obscura. Three of these only are found in Great Britain; the hirundo, minuta, and fissipes. See Plate Nat. Hist. fig. 377.

1. The hirundo, common tern, or great sea-swallow, weighs four ounces one quarter; the length is fourteen inches; the breadth thirty; the bill and feet are of a fine crimson; the former tipt with black, straight, slender, and sharp-pointed; the crown, and hind part of the head, black; the throat, and whole underside of the body, white; the upper part, and the coverts of the wings, a fine pale-grey. This is a very common species, frequents our sea-coasts, and banks of lakes and rivers during the summer, but is most common in the neighbourhood of the sea. It is found also in various parts of Europe and Asia, according to the season; in the summer, as far as Greenland and Spitzbergen, migrating in turn to the South of Austria and Greece. It lays three or four eggs about the month of June, of a dull olive-colour.

These are laid among the grass or moss. The young are hatched in July, and quit the nest very soon after. They are carefully fed by their parents, and fly in about six weeks. This bird appears to have all the actions on the water which the swallow has on land, skimming on the surface, and seizing on every insect which comes in its way; besides which, the moment it spies a fish in the water, it darts into that element, and seizing its prey, arises as quickly to the place from which it dipped.

2. The minuta, or smaller sea-swallow, weighs only two ounces five grains; the length is eight inches and a half, the breadth nineteen and a half. The bill is yellow, tipt with black; the forehead and cheeks white; from the eyes to the bill is a black line; the top of the head and hind part black; the breast and under side of the body clothed with feathers so closely set together, and of such an exquisite rich gloss and so fine a white, that no satin can be compared to it. These two species are very delicate, and seem unable to bear the inclemency of the weather on our shores during winter, for we observe that they quit their breeding-place at the approach of it, and do not return till spring. The manners, haunts, and food, of this species, are the same with those of the former; but they are far less numerous.

3. The fissipes, or black tern, is of a middle size between the first and second species. The usual length is ten inches; the breadth 24; the weight two ounces and a half. The head, neck, breast, and belly, as far as the vent, are black; beyond is white; the male has a white spot under its chin; the back and wings are of a deep ash-colour; the tail is short and forked; the exterior feather on each side is white; the other ash-coloured; the legs and feet of a dusky red. These birds frequent fresh waters, breed on their banks, and lay three small eggs of a deep olive-colour, much spotted with black. They are found during spring and summer in vast numbers in the fens of Lincolnshire, make an incessant noise, and feed on flies as well as water-insects and small fishes. Birds of this species are seen very remote from land.

STERNOPTYX, a genus of fishes of the order apodes. The generic character is head obtuse, teeth very minute; gill membrane 0; body compressed, without apparent scales; breast, carinate folded; belly pellucid. There is but a single species, that inhabits America, viz. diaphana.

STERNUM. See ANATOMY.

STEWARD, a man appointed in a place or stead, and always signifies a principal officer within his jurisdiction. The greatest of these is the lord-high-steward of England; but the power of this officer being very great, of late he has not usually been appointed for any length of time, but only for the dispatch of some special business, as the trial of some nobleman in cases of treason, &c. after which his commission expires.

STICKLEBACK. See GASTEROSTEUS.

STICKS, *foot*, in printing, slips of wood that lie between the foot of the page and the chase, to which they are wedged fast by the quoins, to keep the form firm, in conjunction with the side-sticks, which are placed at the side of the page, and fixed in the same manner by means of quoins.

STIGMA, in entomology, a spot or anastomosis in the middle of the wings of insects near the anterior margin, conspicuous in the hymenopterous tribes.

STIGMATA, in natural history, the apertures in different parts of the bodies of insects communicating with the tracheæ, or air-vessels, and serving for the office of respiration.

STIGMATIZING, among the antients, was inflicted upon slaves as a punishment, but more frequently as a mark to know them by; in which case it was done by applying a red-hot iron marked with certain letters to their foreheads, till a fair impression was made, and then pouring ink into their furrows, that the inscription might be the more conspicuous. Stigmatizing, among some nations, was, however, looked upon as a distinguishing mark of honour and nobility.

STILAGO, a genus of plants belonging to the class of gynandria, and order of triandria. There is one female. The calyx is monophyllous, and almost three-lobed. There is no corolla, and the berry is globular. There are two species, the bunius and diandria, trees of the East Indies.

STILBE, in botany, a genus of plants belonging to the class of polygamia, and order of diœcia. The exterior calyx of the hermaphrodite flower is triphyllous; the interior is quinquedentate and cartilaginous. The corolla is funnel-shaped and quinquefid. There are four stamina; and there is one seed in the interior calyx calyptrate. The female flower is similar, has no interior calyx nor fruit. There are three species, the pinastra, ericoides, and cernua, all foreign plants.

STILBITE. This stone was first formed into a distinct species by Mr. Hauy. Formerly it was considered as a variety of zeolite.

The primitive form of its crystals is a rectangular prism, whose bases are rectangles. It crystallizes sometimes in dodecahedrons, consisting of a four-sided prism with hexagonal faces, terminated by four-sided summits, whose faces are oblique parallelograms; sometimes in six-sided prisms, two of whose solid angles are wanting, and a small triangular face in their place.

Its texture is foliated. The laminæ are easily separated from each other, and are somewhat flexible. Lustre pearly. Hardness inferior to that of zeolite, which scratches stilbite. Brittle. Specific gravity 2.500. Colour pearl white, or greasy. Powder bright white, sometimes with a shade of red. This powder, when exposed to the air, cakes and adheres as if it had absorbed water. It causes syrup of violets to assume a green colour. When stilbite is heated in a porcelain crucible, it swells up and assumes the colour and semitransparency of baked porcelain. By this process it loses 0.185 of its weight. Before the blowpipe it froths like borax, and then melts into an opaque white coloured enamel. Does not gelatine in acids. Not electric by heat.

According to the analysis of Vauquelin, it is composed of

52.0	silica
17.5	alumina
9.0	lime
18.5	water
97.0.	

It occurs most commonly in lava, but is found also in primitive rocks.

STILL. See Distillation.

STILLINGIA, a genus of plants belonging to the class of monœcia, and to the order of monadelphia. The male calyx is hemispherical and multiflorous. The corolla is tubulous, and erose or gnawed. The female calyx is uniflorous and inferior. The corolla is superior. The style is trifid, and the capsule three-grained. There is only one species, the sylvatica.

STING, an apparatus in the body of certain insects, in form of a little spear, serving them as a weapon of offence. The sting of a bee or wasp is a curious piece of mechanism: it consists of a hollow tube, at the root whereof there is a bag full of sharp penetrating juice, which in stinging is injected into the flesh, through the tube; within the tube, Mr. Derham has observed, there lie two sharp small bearded spears. In the sting of a wasp he told eight beards on the side of each spear, somewhat like the beards of fish-hooks. One of these spears in the sting, or sheath, lies with its point a little before the other, to be ready, as should seem, to be first darted into the flesh, which once fixed by means of its foremost beard, the other then strikes too, and so they alternately pierce deeper and deeper, their beards taking more and more hold in the flesh; after which the sheath or sting follows to convey the poison into the wound, which, that it may pierce the better, is drawn into a point with a small slit below that point for the two spears to come out at. By means of these beards it is, that the animal is forced to leave its sting behind it, when disturbed, because it can have no time to withdraw the spears into the scabbard.

STIPA, *feather-grass*, a genus of plants belonging to the class of triandria, and order of digynia, and in the natural system ranging under the 4th order, gramina. The calyx is bivalved. The exterior valve of the corolla is terminated by an awn; the base is jointed. There are 14 species. Of these one only is British; the pennata, or common feather-grass. The beards are feathered. The plant rises to the height of ten inches, grows on mountains, and flowers in July or August.

STIPULA. See Botany.

STIRRUP *of a ship*, a piece of timber put upon a ship's keel, when some of her keel happens to be beaten off, and they cannot come conveniently to put or fit in a new piece; then they patch in a piece of timber, and bind it on with an iron, which goes under the ship's keel, and comes up on each side of the ship, where it is nailed strongly with spikes, and this they call a stirrup.

STOCKING, the clothing of the leg and foot. Antiently the only stockings in use were made of cloth, or of milled stuffs, sewed together; but since the invention of knitting and weaving stockings of silk, wool, cotton, thread, &c. the use of cloth stockings is obsolete. The modern stockings, whether woven or knit, are a kind of plexuses, formed of an infinite number of little knots, called stitches, loops or mashes, intermingled with one another. Knit stockings are wrought with needles made of polished iron or brass wire, which interweave the threads, and form the meshes the stockings consist of. This operation is called knitting, the invention whereof is commonly attributed to the Scots, on this ground, that the first works of this kind came from thence. It is added, that it was on this account that the company of stocking-knitters established at Paris, in 1527, took for their patron St. Fiacre, who is said to be the son of a king of Scotland. Woven stockings are ordinarily very fine; they are manufactured in a frame, or machine of polished iron, the structure and apparatus whereof being exceedingly ingenious, are represented in Plate Miscel. fig. 225. where E is the stocking frame, or engine, 1. Are the treadles, like those of other sorts of looms: 2. is the bobbin of twisted silk, &c. fixed on the bobbin-wire, which it turns with ease to feed the engine: 3. is the wheel, by whose motion the jacks are drawn together upon the needles: 4. is the silk, &c. which runs off the bobbin, and is in that posture directed up to the needle to be looped: 5 is the needle on which the stockings are made according to art.

The loom has received many improvements, so that stockings of all sorts can be made on it with great expedition. By means of some additional machinery to the common stocking-frame, the turned ribbed stockings are made as well as those done with knitting-needles. Stocking-looms will cost from fifty to a hundred and fifty guineas each.

STOCK-JOBBING, a species of trade, or of commercial gambling, which has arisen in most states which are encumbered with national debts. It consists chiefly in making contracts for shares in the public funds against any certain period of time, without an actual transfer of stock being made at the time the bargain is concluded, and generally without any intention of making a transfer at all, the object of the transaction being to pay or receive at the time agreed for the difference between the price the funds may then be at, and the price when the bargain was made. Agreements to deliver stock at a certain price at a future period, began in England about the year 1693, in East India stock, and the practice increased greatly during the high discount upon all government securities about the year 1696, in consequence of which an act was passed for restraining the ill practices of brokers and stock-jobbers, by which the number of brokers was limitted to 100. The establishment of the new East India company, and the subsequent union of the two companies, had probably greater effect in lessening this species of gambling than the restrictions of the act; for while opportunities for speculation exist, some mode of carrying it on will generally be found. Thus in the year 1720, the fallacious project of the South Sea company offering a strong temptation to speculators, stock-jobbing was carried to an enormous extent, which ended in the ruin of thousands. When the mischief was done, a bill was brought into parliament to prevent this "infamous practice," though the experience of the past might have been considered as the best security that it would never again be carried to the same height. The act passed was soon found ineffectual, in consequence of which another bill was brought in by sir John Barnard in 1732, which being rejected, it was brought forward again in 1734, and passed. It is stat. 7. and 8. Geo. 2. c. 8. and declares all contracts and agreements whatsoever, upon which any premium shall be given or paid for liberty to deliver, receive, accept, or refuse any public or joint stock, or other public securities, or any part, share, or interest therein, and all wagers and contracts in the nature of puts and refusals to the then present or future price of such stock or securities, to be null and void, and the money paid thereon shall be restored, or it may be recovered by action commenced thereon within six months, with double costs.

All contracts and agreements whatsoever, made or entered into for buying, selling, assigning, or transferring any public or joint stock, or other public securities whatsoever, or of any part, share, or interest therein, whereof the person or persons contracting or agreeing, or on whose behalf the contract or agreement shall be made, to sell, assign, and transfer the same, shall not, at the time of making such contract or agreement, be actually possessed of, or entitled unto, in his, her, or their own name or names, or in trust for their use, are null and void to all intents and purposes whatsoever; and all and every person whatsoever contracting or agreeing, or on whose behalf, or with whose consent any contract or agreement shall be made to sell, assign, or transfer any public or joint stock or stocks, or other public securities, whereof such person or persons shall not, at the time of making such contract or agreement, be actually possessed of, or entitled unto, in their own name, or in the names of trustees to their use, shall forfeit 500*l*.

Notwithstanding these prohibitions and penalties, the practice of stock-jobbing has continued, and greatly increased; and though it is certainly attended with many evil consequences, it is doubtful whether, if possible, it would be politic to prevent it, while the public debt continues of such enormous amount; as the current value of the public funds would frequently be greatly depressed if it was not supported by the transactions of those who make a regular trade of dealing therein.

STOCKS, the public funds of the nation instituted for the purpose of paying the interest upon loans. See Loan.

Stocks, among ship-carpenters, a frame of timber, and great posts made ashore, to build pinnaces, ketches, boats, and such small craft, and sometimes small frigates. Hence we say, a ship is on the stocks when she is a building.

Stocks, a wooden machine to put the legs of offenders in, for the securing of disorderly persons, and by the way of punishment in divers cases, ordained by statute, &c. And it is said, that every vill within the precinct of a torn is indictable for not having a pair of stocks, and shall forfeit 5*l*.

STOEBE, a genus of the syngenesia polygamia segregata class of plants; the corolla of all the floscules is equal; the proper one is monopetalous and funnel-shaped; the limb is quinquefid and patulous; there is no pericarpium; the seed, which is contained in the cup, is solitary, oblong, and crowned with a long hairy pap. There are nine species.

STOKESIA, a genus of the syngenesia polygamia æqualis class and order of plants. The corollets in the ray are funnel-form, longer, irregular; down four-bristled; recept. naked. There is one species, a herb of South Carolina.

STOLE, *groom of the*, the eldest gentleman of his majesty's bed-chamber, whose office and honour it is to present and put on his majesty's first garment, or shirt, every morning, and to order the things in the chamber.

STOLEN GOODS. To help people to stolen goods for reward without apprehending the felon, is felony. 4 G. I. c. 11.

Persons having or receiving lead, iron, copper, brass, bell-metal, or solder, knowing the same to be stolen, shall be transported. 29 G. II. c. 30.

STOMACH. See Anatomy.

STOMATEUS, a genus of fishes of the order apodes; the generic character is, head compressed; teeth in the jaws and palate; body oval, broad, slippery; tail forked. There are three species, viz. the fiatola, body beautifully barred, inhabits the Mediterranean and Red seas; has two stomachs: paru back gold-colour; belly silvery; inhabits South America: and the cumara, back blue; belly white; inhabits the fresh waters of Chili; is about a span long, and not crossed with stripes.

STOMOXYS, a genus of insects of the order diptera: the generic character is, sucker with a single-valved sheath, inclosing bristles, each in its proper sheath; feelers two, short, setaceous, of five articulations; antennæ setaceous. There are 16 species.

STONE, *calculus humanus*. See Calculi, and Medicine.

Stones from the atmosphere. See Meteoric stones.

Stones. See Mineralogy.

Stones and Earths, *analysis of*. The only substances which enter into the composition of the simple stones, as far at least as analysis has discovered, are the six earths, silica, alumina, zirconia, glucina, lime, and magnesia; and the oxides of iron, manganese, nickel, chromium, and copper. Seldom more than four or five of these substances are found combined together in the same stone: we shall suppose, however, in order to prevent unnecessary repetitions, that they are all contained in the mineral which we are going to analyse.

Let 100 or 200 grains of the stone to be analysed, previously reduced to a fine powder, be mixed with three times its weight of pure potass and a little water, and exposed in a silver crucible to a strong heat. The heat should at first be applied slowly, and the matter should be constantly stirred to prevent the potass from swelling and throwing any part out of the crucible. When the whole water is evaporated, the mixture should be kept for half an hour or three quarters in a strong red heat.

If the matter in the crucible melts completely, and appears as liquid as water, we may be certain that the stone which we are analysing consists chiefly of silica; if it remains opaque, and of the consistence of paste, the other earths are more abundant; if it remains in the form of a powder, alumina is the prevalent earth. If the matter in the crucible is of a dark or brownish red colour, it contains oxide of iron; if it is grass-green, manganese is present; if it is yellowish green, it contains chromium.

When the crucible has been taken from the fire and wiped on the outside, it is to be placed in a capsule of porcelain, and filled with water. This water is to be renewed, from time to time, till all the matter is detached from the crucible. The water dissolves a part of the combination of the alkali with the silica and alumina of the stone; and if a sufficient quantity was used, it would dissolve the whole of that combination.

Muriatic acid is now to be poured in till the whole of the matter is dissolved. At first a flaky precipitate appears, because the acid combines with the alkali which kept it in solution. Then an effervescence takes place, owing to the decomposition of some carbonat of potass formed during the fusion. At the same time the flaky precipitate is redissolved; as is also that part of the matter which, not having been dissolved in the water, had remained at the bottom of the dish in the form of a powder. This powder, if it consists only of silica and alumina, dissolves without effervescence; but if it contains lime, an effervescence takes place.

If this solution in muriatic acid is colourless, we may conclude that it contains no metallic oxide, or only a very small portion; if its colour is purplish red, it contains manganese; orange-red indicates the presence of iron; and golden yellow the presence of chromium.

This solution is to be poured into a capsule of porcelain, covered with paper, and evaporated to dryness in a sand-bath. When the evaporation is drawing towards its completion, the liquor assumes the form of jelly. It must then be stirred constantly with a glass or porcelain rod, in order to facilitate the disengagement of the acid and water, and to prevent one part of the matter from being too much, and another not sufficiently, dried. Without this precaution, the silica and alumina would not be completely separated from each other.

When the matter is reduced almost to a dry powder, a large quantity of pure water is to be poured on it; and, after exposure to a slight heat, the whole is to be poured on a filtre. The powder which remains upon the filtre is to be washed repeatedly, till the water with which it has been washed ceases to precipitate silver from its solutions. This powder is the whole of the silica which the stone that we are analysing contained. It must first be dried between folds of blotting paper, then heated red-hot in a platinum or silver crucible, and weighed while it is yet warm. It ought to be a fine powder, of a white colour, not adhering to the fingers, and entirely soluble in acids. If it is coloured, it is contaminated with some metallic oxide; and shews that the evaporation to dryness has been performed at too high a temperature. To separate this oxide, the silica must be boiled with an acid, and then washed and dried as before. The acid solution must be added to the water which passed through the filtre, and which we shall denominate A.

The watery solution A is to be evaporated till its quantity does not exceed 30 cubic inches, or nearly an English pint. A solution of carbonat of potass is then to be poured into it till no more matter precipitates. It ought to be boiled a few moments to enable all the precipitate to fall to the bottom. When the whole of the precipitate has collected at the bottom, the supernatant liquid is to be decanted off; and water being substituted in its place, the precipitate and water are to be thrown upon a filtre. When the water has run off, the filtre with the precipitate upon it is to be placed between the folds of blotting paper. When the precipitate has acquired some consistence, it is to be carefully collected by an ivory knife, mixed with a solution of pure potass, and boiled in a porcelain capsule. If any alumina or glucina is present, they will be dissolved in the potass; while the other substances remain untouched in the form of a powder, which we shall call B.

Into the solution of potass as much acid must be poured as will not only saturate the potass, but also completely redissolve any precipitate which may have at first appeared. Carbonat of ammonia is now to be added in such quantity that the liquid shall taste of it. By this addition the whole of the alumina will be precipitated in white flakes, and the glucina will remain dissolved, provided the quantity of carbonat of ammonia used is not too small. The liquid is now to be filtred; and the alumina which will remain on the filtre is to be washed, dried, heated red-hot, and then weighed. To see if it is really alumina, dissolve it in sulphuric acid, and add a sufficient quantity of sulphat of acetat of potass; if it is alumina, the whole of it will be converted into crystals of alum.

Let the liquid which has passed through the filtre be boiled for some time; and the glucina, if it contains any, will be precipitated in a light powder, which may be dried and weighed. When pure, it is a fine, soft, very light, tasteless powder, which does not concrete when heated, as alumina does.

The residuum B may contain lime, magnesia, and one or more metallic oxides. Let it be dissolved in weak sulphuric acid, and the solution evaporated to dryness. Pour a small quantity of water on it. The water will dissolve the sulphat of magnesia and the metallic sulphats; but the sulphat of lime will remain undissolved, or if any portion dissolves, it may be thrown down by the addition of a little weak alcohol. Let it be heated red-hot in a crucible, and weighed. The lime amounts to 0.43 of the weight.

Let the solution containing the remaining sulphats be diluted with a large quantity of water; let a small excess of acid be added; and then let a saturated carbonat of potass be poured in. The oxides of chromium, iron, and nickel, will be precipitated, and the magnesia and oxide of manganese will remain dissolved. The precipitate we shall call C.

Into the solution let a solution of hydrosulphuret of potass be poured, and the manganese will be precipitated in the state of a hydrosulphuret. Let it be calcined in contact with air, and weighed. The magnesia may then be precipitated by pure potass, washed, exposed to a red heat, and then weighed.

Let the residuum C be boiled repeatedly with nitric acid, then mixed with pure potass; and after being heated, let the liquid be decanted off. Let the precipitate, which consists of the oxides of iron and nickel, be washed with pure water; and let this water be added to the solution of the nitric acid and potass. That solution contains the chromium converted into an acid. Add to this solution an excess of muriatic acid, and evaporate till the liquid assumes a green colour; then add a pure alkali. The chromium precipitates in the state of an oxide, and may be dried and weighed.

Let the precipitate, consisting of the oxides of iron and nickel, be dissolved in muriatic acid; add an excess of ammonia; the oxide of iron precipitates. Let it be washed, dried, and weighed.

Evaporate the solution, and the oxide of nickel will also precipitate, or the whole may be precipitated by adding hydrosulphuret of ammonia; and its weight may be ascertained in the same manner as the other ingredients.

The weights of all the ingredients obtained are now to be added together, and their sum total compared with the weight of the matter submitted to analysis. If the two are equal, or if they differ only by .03 or .04 parts, we may conclude that the analysis has been properly performed; but if the loss of weight is considerable, something or other has been lost. The analysis must therefore be repeated with all possible care. If there is still the same loss of weight, we may conclude that the stone contains some substance, which has either evaporated by the heat, or is soluble in water.

A fresh portion of the stone must therefore be broken into small pieces, and exposed in a porcelain crucible to a strong heat. If it contains water, or any other volatile substance, it will come over into the receiver; and its nature and weight may be ascertained.

If nothing comes over into the receiver, or if what comes over is not equal to the weight wanting, we may conclude that the stone contains some ingredient which is soluble in water.

To discover whether it contains potass, let the stone, reduced to an impalpable powder, be boiled five or six times in succession with very strong sulphuric acid, applying a pretty strong heat towards the end of the operation, in order to expel the excess of acid; but taking care that it is not strong enough to decompose the salts which have been formed.

Water is now to be poured on; and the residuum, which does not dissolve, is to be washed with water till it becomes tasteless. The watery solution is to be filtred, and evaporated to dryness, in order to drive off any excess of acid which may be present. The salts are to be again dissolved in water; and the solution, after being boiled for a few moments, is to be filtred and evaporated to a consistence proper for crystallizing. If the stone contains a sufficient quantity of alumina, and if potass is present, crystals of alum will be formed: and the quantity of potass may be discovered by weighing them, it being nearly $\frac{1}{10}$th of their weight. If the stone does not contain alumina, or not in sufficient quantity, a solution of pure alumina in sulphuric acid must be added. Sometimes the alum, even when potass is present, does not appear for several days, or even weeks; and sometimes, when a great quantity of alumina is present, if the solution has been too much concentrated by evaporation, sulphat of alumina prevents the alum from crystallizing at all. Care, therefore, must be taken to prevent this last source of error. The alum obtained may be dissolved in water, and barytes water poured into it as long as any precipitate forms. The liquor is to be filtred, and evaporated to dryness. The residuum will consist of potass and a little carbonat of potass. The potass may be dissolved in a little water. This solution, evaporated to dryness, gives us the potass pure, which may be examined and weighed.

If no crystals of alum can be obtained, we must look for some other substance than potass. The stone, for instance, may contain soda. The presence of this alkali may be discovered by decomposing the solution in sulphuric acid, already described, by means of ammonia. The liquid which remains is to be evaporated to dryness, and the residuum is to be calcined in a crucible. By this method, the sulphat of ammonia will be volatilized, and the soda will remain. It may be redissolved in water, crystallized, and examined.

If sulphuric acid does not attack the stone, as is often the case, it must be decomposed by fusion with soda, in the same manner as formerly directed with potass. The matter, after fusion, is to be diluted with water, and then saturated with sulphuric acid. The solution is to be evaporated to dryness, the residuum again dissolved in water, and evaporated. Sulphat of soda will crystallize first; and by a second evaporation of the stone, contains potass and alumina, crystals of alum will be deposited.

Stones, *earthy*. Cronstedt divided this order into nine genera, corresponding to nine earths; one of which he thought composed the stones arranged under each genus. The names of his genera were, calcareæ, siliceæ, granatinæ, argillaceæ, micaceæ, fluores, asbestinæ, zeolithicæ, magnesiæ. All his earths were afterwards found to be compounds, except the first, second, fourth, and ninth. Bergman, therefore, in his Sciagraphia, first published in 1782, reduced the number of genera to five; which was the number of primitive earths known when he wrote. Since that period five new earths have been discovered. Accordingly, in the latest systems of mineralogy, the genera belonging to this order are proportionably increased. Each genus is named from an earth, as follows:

1. Jargon genus,	5. Magnesian genus,
2. Siliceous genus,	6. Calcareous genus,
3. Glucina genus,	7. Barytic genus,
4. Argillaceous genus,	8. Strontian genus.

Mr. Kirwan, in his valuable system of mineralogy, has adopted the same genera. Under each genus those stones are placed which are composed chiefly of the earth which gives a name to the genus, or which at least are supposed to possess the characters which distinguish that earth.

A little consideration will be sufficient to discover that there is no natural foundation for these genera. Most stones are composed of two, three, or even four, ingredients; and in many cases the proportion of two or more of these is nearly equal. Now, under what genus soever such minerals are arranged, the earth which gives it a name must form the smallest part of their composition. Accordingly, it has not been so much the chemical composition as the external character, which has guided the mineralogist in the distribution of his species. The genera cannot be said properly to have any character at all, nor the species to be connected by any thing else than an arbitrary title. This defect, which must be apparent in the most valuable systems of mineralogy, seems to have arisen chiefly from an attempt to combine together an artificial and natural system.

The only substances which enter into the minerals belonging to this order, in such quantity as to deserve attention, are the following:

8

Alumina,	Oxide of iron,
Silica,	Oxide of chromium,
Magnesia,	Oxide of nickel,
Lime,	Oxide of copper,
Barytes,	Potass,
Glucina,	Soda,
Zirconia,	Water.
Yttria,	

Stones, *saline*. Under this arrangement are comprehended all the minerals which have an earthy basis combined with an acid. The minerals belonging to it are of course salts, and as such have been described under their respective names. But as they occur native in states which cannot always be imitated by art, it will be necessary to take a view of them as they are found in the earth. They naturally divide themselves into five genera; as only five earths have hitherto been discovered native in combination with an acid. These genera, and the species belonging to them, are the following:

I. Calcareous Salts.
1. Carbonat of lime,
2. Sulphat of lime,
3. Phosphat of lime,
4. Fluat of lime,
5. Arseniat of lime.

II. Barytic Salts.
1. Carbonat of barytes,
2. Sulphat of barytes.

III. Strontian Salts.
1. Carbonat of strontian,
2. Sulphat of strontian.

IV. Magnesian Salts.
1. Sulphat of magnesia,
2. Carbonat of magnesia,
3. Borat of magnesia.

V. Aluminous Salts.
1. Alum,
2. Mellat of alumina,
3. Fluat of alumina-and-soda.

The minerals belonging to this order are distinguished without much difficulty from the last. Almost all of them are insoluble in water; but soluble in nitric acid, or in hot sulphuric acid. Most of them melt before the blowpipe. Their specific gravity varies; but it is often above 3.5 when the mineral is too soft to scratch glass. None of them have the metallic lustre.

STONEHENGE, in antiquity, a famed pile or monument of huge stones on Salisbury plain, six miles distant from that city.

It consists of the remains of four ranks of rough stones, ranged one within another, some of them, especially in the outermost and third rank, twenty feet high, and seven broad; sustaining others laid across their heads and fastened by mortises, so that the whole must have antiently hung together.

Antiquaries are now pretty well agreed that it was a British temple; and Dr. Langwith thinks it might easily be made probable at least, that it was dedicated to the sun and moon.

STONE WARE. Under the denomination stone ware are comprehended all the different artificial combinations of earthy bodies which are applied to useful purposes. These vary in their names according to their external appearance, the manner in which they are manufactured, and the purposes to which they are applied. Thus we have porcelain, stone ware, pots, crucibles, bricks, tiles, &c. All these substances, however, are formed on the same principles, nearly of the same materials, and owe their good qualities to the same causes.

These combinations have been known from the remotest ages of antiquity. They were well known to the Jews, as we learn from the Old Testament, long before the Babylonish captivity. Porcelain, or the finest kind of stone ware, was early brought to perfection in China and Japan; but the discovery of the art of making it in Europe is of much later date.

Specimens of it were brought first from China and Japan to modern Europe. These were admired for their beauty, were eagerly sought after, and soon became the ornaments of the tables of the rich. Various attempts were made to imitate them in different countries of Europe, but the greater number were without success. Accident led to the discovery in Germany about the beginning of the 18th century. A chemist in Saxony, during a set of experiments in order to ascertain the best mixtures for making crucibles, stumbled upon a compound which yielded a porcelain similar to the eastern. In consequence of this discovery, Saxony soon produced porcelain scarcely inferior to that of Japan in beauty, and superior to it in solidity and strength: but its composition was kept secret; nor were there any accurate ideas respecting the component parts of porcelain among men of science, till Reaumur published his dissertations on the subject in 1727 and 1729. He examined the porcelain of Japan, and the different imitations of it which had been produced in France and other parts of Europe. The texture of the first was compact and solid, but that of the imitations was porous. When both were exposed to a strong heat, the first remained unaltered, but the others melted into glass. From these experiments he drew the following ingenious conclusions:

Porcelain owes its semitransparency to a kind of semivitrification which it has undergone. Now it may receive this two ways: 1. Its component parts may be such as easily vitrify when sufficiently heated; but the degree of heat given may be just sufficient to occasion a commencement of vitrification. This porcelain when strongly heated will easily melt. Such, therefore, was the composition of the European imitations of porcelain. 2. It may be composed of two ingredients; one of which easily vitrifies, but the other is not altered by heat. When a porcelain composed of such materials is baked in a sufficient heat, the fusible part melts, invelopes the infusible, and forms a semitransparent substance, which is not farther altered by the same degree of heat. Such therefore must be the porcelain of Japan. Father Entrecolles, a missionary to China, had sent an account of the Chinese mode of making porcelain, which coincided exactly with this ingenious thought of Reaumur. The ingredients, according to him, are a hard stone called petunse, which they grind to powder, and a white earth called kaolin, which is intimately mixed with it. Reaumur found the petunse fusible, and the kaolin infusible, when exposed separately to a violent heat. See Porcelain

Stone ware is not formed by mixing together the pure earths, which would be a great deal too expensive; but natural combinations or mixtures of earths are employed. These combinations must possess the following properties: 1. They must be capable, when reduced to powder, of forming with water a paste sufficiently ductile to be made into any form which is required. 2. This paste, after being exposed to a sufficient heat, or after being baked as it is termed, must acquire such a permanent degree of hardness as to be able to resist the action of the weather and of water. 3. The vessels formed of it must in that state be capable of resisting changes of temperature. 4. They must be able to resist a strong heat without being melted. 5. They must not be permeable to liquids, nor liable to be acted on by chemical agents.

Common clay possesses a good many of these qualities. When finely ground, it may be formed into a very ductile paste; heat makes it hard enough to strike fire with steel, and capable of resisting the action of most chemical agents; and it is not liable to be melted by heat. Clay accordingly was the first substance employed, and it is still employed for a variety of purposes.

Bricks, for instance, are always made of this substance. The clay is dug out of the earth, and after being exposed for some time to the air is reduced to powder, and formed into a paste with water. The bricks are then formed in moulds, exposed for some time to dry in the open air, and then burnt in a large furnace constructed on purpose. Tiles which are employed for covering houses are formed in the same way. The clay, however, is finer, and it is usually ground in a mill.

Bricks and tiles should be impervious to water: they should be capable of withstanding the action of heat, and not be subject to moulder. It is obvious that these qualities must depend upon the nature of the clay of which they are formed, and on the degree in which they have been burned. Clay is a mixture of alumina and silica in various proportions. When the proportion of alumina is great, the brick contracts much in its dimensions, and is apt to crack during the burning. Clay therefore must be chosen which contains the proper proportion of silica, or the defect must be remedied by adding sand. Bergman recommends the addition of a little lime, which has the property of rendering the clay fusible. The clay of which bricks and tiles are made contains some oxide of iron: hence the red colour which it acquires when burnt.

But though the addition of lime may be proper in some cases in the manufacture of bricks and tiles, it would be exceedingly improper in other cases. Lime ought to be carefully excluded from the clay destined for making pots, and every other utensil which is to be exposed to a violent heat, as it renders the clay fusible. Now lime enters not unfrequently into the composition of clays. It is evident therefore that all clays are not proper for the manufacture of stone ware. They must be free from lime, barytes, and every other ingredient which renders them fusible. They must also be free from metallic oxides, which not only render them fusible, but also injure the colour of the porcelain. The clays which answer are those which consist of a mixture of alumina and silica. These are known by the names of potter's clay, tobacco-pipe clay, porcelain-clay, &c. according to the purposes to which they are applied. It is necessary to mix the clay with some fine colourless sand, in order to prevent the vessels from contracting too much during the baking.

Thus stone ware is composed of two materials, pure clay and sand; and the beauty of the ware depends upon the purity and fineness of these two materials. What is called English stone ware is composed of tobacco-pipe clay and powdered flints; delft ware is composed of clay and fine sand; and the coarsest wares of still more common clay and sand.

The materials are ground very fine in a mill, then mixed together, and formed into a paste. The different vessels are coarsely moulded on the potter's wheel, and allowed to dry till they can bear handling. After this they receive their destined form completely; and when they are sufficiently dry, they are covered with the requisite enamel, and then put into the furnace and baked.

Such, in general, is the method of manufacturing stone ware. The particular processes followed in the making of porcelain are concealed by the manufacturers; but the component parts are always analogous to those pointed out by Reaumur. The refractory ingredient is a fine white clay, consisting essentially of alumina and silica, and the fusible ingredient is a mixture of siliceous sand and lime.

It is necessary to glaze the surface of vessels, whether of stone ware or porcelain, both for the purpose of beauty and utility; for the body of the vessel, or biscuit as it is called, would not be sufficiently compact to contain liquids. Now this glazing is of three kinds: 1. A vitrified metallic oxide. 2. An enamel. 3. A glass. The first is applied to the coarsest vessels, the second to fine kinds of stone ware, the third to porcelain.

The glazing of coarse vessels is formed by covering their surface while hot with a little litharge, which has the property of running into an opaque glass at a moderate heat when spread thin upon an earthen vessel. The colour of this glazing is yellow or red. It is seldom perfect; hence these coarse vessels are frequently porous, and incapable of resisting the action of corrosive substances. Common salt is sometimes employed instead of lead. It facilitates the fusion of the surface of stone ware, and occasions a kind of vitrification.

The glazing of fine vessels consists of white enamel. This is made as follows: one hundred parts of lead are melted with from 15 to 40 parts of tin, and the mixture oxidized completely, by exposing it to heat in an open vessel. One hundred parts of this oxide are mixed with 100 parts of a fine white sand composed of three parts silica and one part of talc, and with about 25 parts of common salt. This mixture is melted, then reduced to powder, and formed into a paste, which is spread thin over the porcelain vessel before it is baked. The excellency of a good enamel is, that it easily fuses into a kind of paste at the heat which is necessary for baking porcelain, and spreads equally on the vessel, forming a smooth glassy surface, without losing its opacity, or flowing completely into a glass. Its whiteness depends upon the proportion of the tin, its fusibility upon the lead.

Porcelain is always covered with a glass, composed of earthy ingredients, without any mixture of metallic oxides. Hence the high temperature necessary to fuse it, and the property which porcelain vessels have of resisting the action of the most corrosive substances precisely as common glass does. The substance commonly employed is felspar; a mineral of a fine white colour and foliated texture, which is found abundantly in the mountains.

It is usual to paint both stone ware and porcelain of various colours. These paintings are often excellent, both in elegance of workmanship and in brilliancy of colours. The colours are given by means of metallic oxides, which are mixed up with other ingredients proper to constitute an enamel, and applied in the usual manner with a pencil.

On this subject much light has been thrown by the experiments of Wedgewood; and Brogniart has lately published a general account of the processes at Sevres, of which he is director.

The process differs a little according to the substance on which the colours are to be applied. When the vessels are covered with enamel, less flux is necessary, because the enamel melts at a low heat, and the colours readily incorporate with it; but this renders them more dilute, and makes it often necessary to retouch them. The colours on enamel generally appear brilliant and soft, and are not liable to scale. The flux is either a glass of flint and lead, or borax mixed with flint glass. The colours are usually made into a paste by means of gum-water or volatile oils. Some of them are liable to alteration by the action of the lead on them.

The colours applied upon hard porcelain, or porcelain glazed with felspar, are nearly the same as those applied on enamel, but more flux is necessary. They are not liable to dilution, as the felspar glaze does not melt at the heat requisite for fusing the colours and their flux. They are liable to scale off when repeatedly heated.

Colours are sometimes applied over the whole surface of the porcelain; the flux in that case is porcelain. But such colours are not numerous, because few oxides can stand the heat necessary for melting felspar without being altered or volatilized.

1. Purple is given by means of the purple oxide of gold precipitated by the smallest possible quantity of muriat of tin. This oxide is mixed with a proper quantity of powdered glass, borax, and oxide of antimony, and applied with a pencil. It cannot bear a strong heat without losing its colour.

2. Red is given by oxide of iron. A mixture of two parts of sulphat of iron and one part of alum is calcined slowly, till it acquires a fine red colour when cold. This powder is mixed with the usual flux, and applied with a pencil.

3. Yellow is given by the oxide of silver; or, by oxides of lead, antimony, and sand; green, by the oxide of copper; blue, by the oxide of cobalt; and violet, by the oxide of manganese.

STOP, in music, a word applied by violin and violoncello performers to that pressure of the strings by which they are brought into contact with the finger-board, and by which the pitch of the note is determined. Hence a string, when so pressed, is said to be stopt.

Stop *of an organ*. A collection of pipes similar in tone and quality, which run through the whole, or a great part, of the compass of the instrument. In a great organ the stops are numerous and multifarious, commonly comprising the following:

Open-diapason stop. A metallic stop which commands the whole scale of the organ, and which is called open in contradistinction to the stopt diapason, the pipes of which are closed at the top.

Stopt-diapason stop. A stop, the pipes of which are generally made of wood, and its base up to middle C always of wood. They are only half as long as those of the open diapason, and are stopped at the upper end with wooden stoppers or plugs, which render the tone more soft and mellow than that of the open diapason.

Principal stop. A metallic stop originally distinguished by that name, because holding, in point of pitch, the middle station between the diapason and fifteenth, it forms the standard for tuning the other stops.

Twelfth stop. A metallic stop so denominated from its being tuned twelve notes above the diapason. This stop, on account of its pitch, or tuning, can never properly be used alone. The open diapason, stopt diapason, principal, and fifteenth, are the best qualified to accommodate it to the ear.

Fifteenth stop. A stop which derives its name from its pitch, or scale, being fifteen notes higher than that of the diapason. This stop and the twelfth, mellowed and embodied by the two diapasons and principal, form a proper compound for accompanying choral parts in common choirs and parochial churches.

Sesquialtera stop. A mixed stop running through the scale of the instrument, and consisting of three, four, and sometimes five ranks of pipes, tuned in thirds, fifths, and eighths. In small organs this stop is generally divided at middle C, when the lower part is called the sesquialtera, and the upper part the cornet. The whole of the stop lies above the fifteenth; the first rank being a seventeenth, the second rank a nineteenth, and the third rank a twenty-second, above the diapason.

Mixture or furniture stop. A stop comprising two or more ranks of pipes, shriller than those of the sesquialtera, and only calculated to be used together with that and other stops. The mixture is nearly the same as the sesquialtera, and greatly enriches the instrument.

Trumpet stop. A reed metallic stop, so called because its tone is imitative of the trumpet. In large organs it generally extends through the whole compass. The mouths of its pipes are not formed like those of the pipes of other stops, but resemble that of the real trumpet. At the bottom of each of the pipes of this stop, in a cavity called the socket, is fixed a brass reed, stopt at the lower end, and open in front; it is furnished with a tongue, or brass ring, which covers the opening, and which, when the wind is impelled into the pipe, is thereby put into a vibratory motion, which produces the imitative tone peculiar to this stop. The trumpet stop is the most powerful in the instrument, and improves the tone, as much as it increases the peal of the chorus. Unisonous with the diapasons, it strengthens the foundation, subdues the dissonances of the thirds and fifths of the sesquialtera, and imparts to the compound a richness and grandeur of effect adequate to the sublimest subjects.

Clarion or octave trumpet stop. A reed stop resembling the tone of the trumpet, as may be inferred from its name; but the scale of which is an octave higher than the trumpet stop. This stop forms a brilliant supplement to the chorus, and is judiciously employed on occasions which require every power of the instrument; but should not be commonly opened, or indeed, ever without the other stops.

Tierce stop. A stop which is tuned a major third higher than the fifteenth, and only employed in the full organ.

Larigot stop, or octave twelfth. A stop, the scale of which is an octave above the twelfth. Only used in the full organ.

Cornet stop. A stop consisting of five pipes to each note, tuned somewhat in the manner of the sesquialtera, having, beside the unison of the diapason, its third, fifth, eighth, and seventeenth. The cornet being only a treble stop, it is employed in parish-churches in conjunction with the diapason in interludes, and the giving out of the psalms.

Dulciana stop. A stop in the choir organ of a peculiar sweetness of tone, which it chiefly derives from the bodies of its pipes being longer and smaller than those of the pipes of other stops. It is in unison with the diapasons, and equals them in compass upward, but only descends to G gamut.

Flute stop. A stop imitative of the common flute, or flageolet. It is in unison with the principal, but of a much softer tone than that stop.

Bassoon stop. A reed stop imitative of the instrument from which it derives its name. This stop, so far as it extends upward in the scale, is in unison with the diapasons, in company with which it only ought to be used.

Vox-humana stop. A reed stop, the tone of which, as its name implies, resembles the human voice. The quality of this stop is seldom so good as to render it agreeable when heard alone; it is therefore advantageously blended with the diapasons, with which it is in unison.

Hautboy stop. A reed stop voiced in imitation of the hautboy. It in unison with the diapasons, with which it only should be used.

Cremona stop. A reed stop in unison with the diapasons. The name of this stop has induced most organ-builders erroneously to suppose that it was originally meant as an imitation of the Cremona violin; but the writers best informed upon the subject inform us, that it was designed to imitate an antient instrument calted a krum-horn, which word has been corrupted into cremona.

STOPPAGE, for the subsistence of the sick. In the regulations for the better management of the sick in regimental hospitals, it is particularly laid down, under the head subsistence, page 16, that sufficient funds should be established for the support of the sick without any additional charge to government; and at the same time, that the sick soldier should be provided with every reasonable comfort and indulgence that can be afforded. The sum of four shillings per week from the pay of each soldier will, under proper regulations, and with strict economy, be sufficient for this purpose; which sum is to be retained by the paymaster of the regiment.

The sick are to be furnished with bread made of the finest wheat-flour, and fresh meat, perfectly good and wholesome.

That the greatest economy may be used in laying out the money for the sick, every article ought to be purchased by the surgeon, who is required to keep a book, in which he is to enter the amount of the weekly consumption of each man according to the diet table; and this book, with the diet table, is to be laid before the commanding officer and paymaster every week, to be examined and signed by each.

STOPPAGES, in a military sense, deductions from a soldier's pay, the better to provide him with necessaries, &c. A soldier should never be put under a greater weekly stoppage from his pay, than what will afterwards leave him a sufficiency for messing. Since the abolition of arrears a regulation has taken place, by which soldiers are directed to be stopped one shilling and sixpence per week in the infantry, and to be accounted with on the 24th of every month.

STORAX. See STYRAX, and RESINS.

STORES. If any person who has the charge or custody of any of the king's armour, ordnance, ammunition, shot, powder, or habiliments of war, or of any victuals for victualling the navy, shall, to hinder his majesty's service, embezzle, purloin, or convey away the same to the value of 20*s.* or shall steal or embezzle any of his majesty's sails, cordage, or any other of his naval stores, to the value of 20*s.* he shall be adjudged guilty of felony without benefit of clergy. 22 Car. II. c. 5.

The treasurer, comptroller, surveyor, clerk of the acts, or any commissioner of the navy, may act as justices in causing the offender to be apprehended, committed, and prosecuted for the same. 9 G. III. c. 30.

If any person shall wilfully and maliciously set on fire, burn, or destroy, any of his majesty's military, naval, or victualling stores, or other ammunition of war, or any place where any such stores or ammunition shall be kept, he and his abettors shall be guilty of felony without benefit of clergy. 12 Geo. III. c. 24.

STORK. See ARDEA.

STOVE, in gardening. See HOT-HOUSE.

STRANDED, among seamen, is said of a ship that is driven ashore by a tempest, or runs on ground through ill steerage, and so perishes. Where any vessel is stranded, the justices of the peace are impowered to command the constables near the sea-coast to call assistance, in order to preserve the same if possible.

STRANGURY. See MEDICINE.

STRAP, in a ship, is a rope spliced about any block, or made with an eye, to fasten it any where, on occasion.

STRATA, in natural history, the several beds or layers of different matters, whereof the body of the earth is composed. See EARTH, *structure of.*

SRTATIFICATION *of the earth.* Scarcely any of the natural phenomena have been so slightly treated of by the philosophers of the present and past ages, as the strata of the earth. Few, if any, among the writers on this curious and interesting subject, have distinguished between the undisturbed or regular strata, forming the solid matter of the earth, and the alluvial or mixed, violently moved, and worn substances, which are found upon its surface; while these again, in their observations, have been in too many instances confounded with the alluvial depositions of rivers and the ocean, formed in modern times, or since they have been confined nearly to their present limits. The effects of vegetation, in accumulating peaty matters, and, in conjunction with frost, alternate wetting and drying, the atmospheric air, and cultivation, in gradually changing the surface of almost any of the stratified matters, to a soil or mould fit for the growth of some kind of vegetables, have in a great degree been overlooked; and accordingly we find a great number of writers, confidently mentioning different series of substances, which they assert, on observations entirely local, to be the order of the strata on proceeding downwards beneath the vegetable soil.

Notwithstanding that Mr. Hauksbee many years ago, at the instance of the Royal Society of London, carefully examined a succession of thirty strata, in the shaft of a coal-pit, and found that strata specifically heavier, were frequently found lodged above lighter strata; yet, a large portion of the writers since, to the present time, have contended that the strata are found deposited in the order, or nearly, of their specific gravities.

John Stracey, esq. a writer in the Philosophical Transactions (No. 391), started an opinion, that the strata were at first formed while in a soft state, as so many wedges, each pointing to and terminating in the centre of the earth; and that by the diurnal revolution of the earth from west to east, these became bent into spirals (as represented in fig. 223, Plate Miscel.), in which case, says he, "there needs no specific gravitation to cause the lightest to be uppermost, &c. for every one in its turn, in some place of the globe or other, will be uppermost;" this last remark, made in the year 1725, we do not remember to have seen noticed by any subsequent writer or observer, although, from a series of minute observations made within the last fifteen years by a gentleman formerly resident at Mitford near Bath, and now in London, Mr. William Smith, there is great reason to think that this is really the case with all the strata composing the surface of the British islands, and perhaps of the whole earth, in what manner soever the strata in the inner parts of the earth may be disposed.

We do not understand that Mr. Smith was at all acquainted with the above remark of Mr. Stracey; but that in the exercise of his profession of a land-surveyor, superintendant of some coal-mines, and engineer for the cutting of the Somerset coal-canal, he saw ample reason to conclude that the several strata in the neighbourhood of Bath, all rise westwardly successively to the surface. His subsequent observations in almost every part of the kingdom, have confirmed this most completely; and we understand that sections and maps of the out-crop of all the principal strata in England, Wales, and part of Scotland, have been prepared and repeatedly submitted by Mr. Smith to the inspection of the learned and curious in these matters; and that a first part or volume on the subject, may shortly be expected from that gentleman. The subject is of immense importance to the owners of the soil, to those who are in search of springs of good and wholesome water, and to mine-owners in particular, while science cannot but be benefited by the new field of investigation which is thus opened.

STRATIOTES, *water-soldier*, a genus of plants belonging to the class of polyandria, and to the order of hexagynia, and in the natural system ranking under the first order, palmæ. The spatha is diphyllous; the perianthium is trifid; there are three petals, and the berry is six-celled and inferior. There are three species, the aloides, the acoroides, and alismoides. The aloides alone is of British extraction, which is also called the water aloe, or fresh-water soldier. The root consists of long fibres tufted at the ends. The leaves are thick, triangular, pointed, and prickly at the edges. The flowers are white and floating on the water, and blossom in June. This plant may be seen in slow rivers and fens.

STRAWBERRY. See FRAGARIA.

STRAWBERRY-TREE. See ARBUTUS.

STRELITZIA, a genus of the class and order pentandria monogynia. The spathes are universal and partial; no calyx; corolla three-petalled; nectarium three-leaved; capsule three-celled; cells many-seeded. There are two species of this magnificent plant, natives of the Cape.

STRENGTH. See TIMBER, *strength of.*

STREPTIUM, a genus of the didynamia angiospermia class and order. The calyx is five-toothed; stigma two-lipped; drupe two-lobed. There is one species.

STRIKE, a measure of capacity, containing four bushels. See MEASURE.

STRIKE, among seamen, is a word variously used. When a ship, in a fight, or on meeting with a ship of war, lets down or lowers her top-sails, at least half-mast-high, they say she strikes, meaning she yields, or submits, or pays respect to the ship of war. Also, when a ship touches ground, in shoal-water, they say she strikes. And when a top-mast is to be taken down, the word of command is, strike the top-mast, &c.

STRIX, the *owl*, in ornithology, a genus belonging to the order of accipitres. The bill is hooked, but has no cere or wax; the nostrils are covered with setaceous feathers; the head is very large, as are also the ears and eyes; and the tongue is bifid. There are 46 species; the most remarkable are,

1. The bubo, or great-eared owl, in size is almost equal to an eagle. Irides bright yellow; the head and whole body finely varied with lines, spots, and specks of black, brown, cinereous, and ferruginous; wings long; tail short, marked with dusky bars; legs thick, covered to the very end of the toes with a close and full down of a testaceous colour; claws great, much hooked and dusky. It has been shot in Scotland and in Yorkshire. It inhabits inaccessible rocks and desert places; and preys on hares and feathered game. Its appearance in cities was deemed an unlucky omen; Rome itself once underwent a lustration because one of them strayed into the capitol. The antients had them in the utmost abhorrence, and thought them, like the screech-owls, the messengers of death. Pliny styles it bubo funebris, and noctis monstrum. See Plate Nat. Hist. fig. 378.

2. The brachyotos, or short-eared owl, is 14 inches long, three feet broad; the head is small and hawk-like; the bill is dusky; weight 14 ounces. The horns of this species are very small, and each consists of only a single feather; these it can raise or depress at pleasure; and in a dead bird they are with difficulty discovered. These species may be called long-winged owls; the wings when closed reaching beyond the end of the tail; whereas, in the common kinds, they fall short of it. This is a bird of passage, and has been observed to visit Lincolnshire in the beginning of October, and to retire early in the spring; so probably, as it performs its migrations with the woodcock, its summer retreat is Norway. During day it lies hid in long old grass; when disturbed, it seldom flies far, but will light, and sit looking at one, at which time the horns may be seen distinctly. It has not been observed to perch on trees like other owls; it usually flies in search of prey in cloudy hazy weather. Farmers are fond of seeing these birds in the fields, as they clear them from mice.

3. The flammea, or common white owl. The elegant plumage of this bird makes amends for the uncouthness of its form; a circle of soft white feathers surround the eyes. This species is almost domestic; inhabiting, for the greatest part of the year, barns, hay-lofts, and other out-houses; and is as useful in clearing those places from the mice as the congenial cat. Towards twilight it quits its perch, and takes a regular circuit round the fields, skimming along the ground in quest of field-mice, and then returns to its usual residence: in the breeding season it resorts to the eaves of churches, holes in lofty buildings, or hollows of trees. During the time the young are in the nest, the male and female alternately sally out in quest of food, make their circuit, beat the fields with the regularity of a spaniel, and drop instantly on their prey in the grass. They very seldom stay out above five minutes; return with their prey in their claws; but as it is necessary to shift it into their bill, they always alight for that purpose on the roof, before they attempt to enter their nest. This species does not hoot, but snores and hisses in a violent manner; and while it flies along will often scream most tremendously. Its only food is mice. As the young of these birds keep their nest for a great length of time, and are fed even long after they can fly, many hundreds of mice will scarcely suffice to supply them with food. Owls cast up the bones, fur, or feathers, of their prey, in form of small pellets, after they have devoured it, in the same manner as hawks do. A gentleman, on grubbing up an old pollard ash that had been the habitation of owls for many generations, found at the bottom many bushels of this rejected stuff. Some owls, when they are satisfied, hide the remainder of their meat like dogs.

4. The stridula, or tawny owl, weighs 19 ounces. This is a hardier species than the former; and the young will feed on any dead thing, whereas those of the white owl must have a constant supply of fresh meat. It is the strix of Aldrovandus, and what we call the screech-owl, to which the folly of superstition has given the power of presaging death by its cries.

5. The ulula, or brown owl, agrees with the former in its marks, differing only in the colours. Both these species inhabit woods, where they reside the whole day; in the night they are very clamorous, and when they hoot, their throats are inflated to the size of a hen's egg. In the dusk they approach our dwellings, and will frequently enter pigeon-houses, and make great havoc in them. They destroy numbers of little leverets, as appears by the legs frequently found in their nests. They also kill abundance of moles, and skin them with as much dexterity as a cook does a rabbit. They build in hollow trees or ruined edifices; lay four eggs, of an elliptic form, and of a whitish colour.

6. The passerina, or little owl, is very rare in England; it is sometimes found in Yorkshire, Flintshire, and also near London. In size it scarcely exceeds a thrush, though the fulness of its plumage makes it appear larger. The Italians make use of this owl to decoy small birds to the limed twig; the method of which is exhibited in Olina's Uccelliera.

7. The spectacle owl of Cayenne, which is accurately described by Dr. Latham, is 21 inches in length: the upper parts of the body are of a reddish colour; the lower parts of a rufous white; the head and neck are white, and not so full of feathers as those of owls generally are, and from this circumstance it appears not unlike a hawk; a large patch of dark brown surrounds each eye, giving the bird much the appearance of wearing spectacles; the legs are covered with feathers quite to the toes, and are of a yellowish colour.

STROMBUS, a genus of the vermes testacea. The generic character is, animal a limax; shell univalve, spiral; aperture much dilated; the lip expanding, and produced into a groove leaning on the left. This genus comprises 53 species, which are separated into divisions. Only one species, viz. the pes pelecane, or corvorant's foot, is found in this country. These shells, in their younger state, want the lip, and have a thin turbinate appearance. On this account they have by many naturalists been referred to a genus to which they do not belong.

STRONGYLUS, a genus of vermes intestina. The generic character is, body round, long, pellucid, glabrous; the fore part is globular, truncate, with a circular aperture fringed at the margin; the hind part of the female entire and pointed; of the male dilated into loose, distant, and pellucid membranes. There are two species: 1, the equinus, that inhabits the stomach of the horse in great numbers; and, 2, the ovinus, found in the intestines of sheep.

STRONTIAN. About the year 1787, a mineral was brought to Edinburgh by a dealer in fossils, from the lead-mine of Strontian, in Argyleshire, where it is found imbedded in the ore, mixed with several other substances. It is sometimes transparent and colourless, but generally has a tinge of yellow or green. Its specific gravity varies from 3.4 to 3.726. Its texture is generally fibrous; and sometimes it is found crystallized in slender prismatic columns of various lengths.

Strontian is found abundantly in different places of the world, and always combined with carbonic acid or sulphuric acid.

1. The carbonic acid may be expelled from the carbonat, and the strontian obtained pure by mixing the mineral with charcoal powder, and exposing it to a heat of 140° Wedgewood; or by dissolving the mineral in nitric acid, evaporating the solution till it crystallizes, and exposing the crystals in a crucible to a red heat till the nitric acid is driven off.

2. Strontian thus obtained, is in porous masses, of a greyish white colour; its taste is acrid and alkaline; and it converts vegetable blues to green. Its specific gravity, according to Hassenfratz, is 1.647. It does not act so strongly on animal bodies as barytes, nor is it poisonous.

It does not melt when heated like barytes; but before the blowpipe it is penetrated with light, and surrounded with a flame so white and brilliant that the eye can scarcely behold it.

3. When water is sprinkled on strontian it is slacked, becomes hot, and falls to powder exactly like barytes; but it is not so soluble in water as that earth. One hundred and sixty-two parts of water, at the temperature of 60°, dissolve nearly one part of strontian. The solution, known by the name of strontian water, is clear and transparent, and converts vegetable blues to a green. Hot water dissolves it in much larger quantities; and as it cools, the strontian is deposited in colourless transparent crystals. These are in the form of thin quadrangular plates, generally parallelograms, the largest of which seldom exceeds one-fourth of an inch in length. Sometimes their edges are plain, but they oftener consist of two facets, meeting together, and forming an angle like the roof of a house. These crystals generally adhere to each other in such a manner as to form a thin plate of an inch or more in length, and half an inch in breadth. Sometimes they assume a cubic form. They contain about 68 parts in 100 of water. They are soluble in 51.4 parts of water, at the temperature of 60°. Boiling water dissolves nearly half its weight of them. When exposed to the air, they lose their water, attract carbonic acid, and fall into powder. Their specific gravity is 1.46.

4. Strontian is not acted on by light; neither does it combine with oxygen.

5. Sulphur and phosphorus are the only simple combustibles with which it unites.

The sulphuret of strontian may be made by fusing the two ingredients in a crucible. It is soluble in water by means of sulphureted hydrogen, which is evolved. When the solution is evaporated, hydrosulphuret of strontian is obtained in crystals, and hydrogenated sulphuret remains in solution. These compounds resemble almost exactly the sulphuret, hydrosulphuret, and hydrogenated sulphuret of barytes; and do not therefore require a particular description. The same remark applies to the phosphuret of strontian, which may be prepared by the same process as the phosphuret of barytes.

6. Strontian does not combine with azote; but it unites readily with muriatic acid, and forms the substance called muriat of strontian.

7. Strontian has no action upon metals; but it combines with several of their oxides, and forms compounds which have not hitherto been examined.

8. It does not combine with alkalies nor with barytes. No precipitation takes place when barytes and strontian water are mixed together.

9. Strontian has the property of tinging flame of a beautiful red, or rather purple colour; a property discovered by Dr. Ash in 1787. The experiment may be made by putting a little of the salt composed of nitric acid and strontian into the wick of a lighted candle; or by setting fire to alcohol, holding muriat of strontian in solution. In both cases the flame is of a lively purple. In this respect it differs from barytes, which when tried in the same way is found to communicate a blueish yellow tinge to flame.

10. The affinities of strontian, as ascertained by Dr. Hope and Mr. Vauquelin, are as follows:

Sulphuric acid,	Muriatic,
Phosphoric,	Succinic,
Oxalic,	Acetic,
Tartaric,	Arsenic,
Fluoric,	Boracic,
Nitric,	Carbonic.

Barytes and strontian resemble each other in their properties as closely as potass and soda: hence, like these two alkalies, they were for some time confounded. It is in their combination with acids that the most striking differences between these two earths are to be observed.

STRUMPFIA a genus of plants belonging to the class of syngenesia, and to the order of monogamia. The calyx is quinquedentate and superior; the corolla is pentapetalous; and the berry monospermous. There is only one species, the maritima, a shrub of Curaçoa.

STRUTHIO, in natural history, a genus of birds belonging to the order of grallæ of Linnæus. It includes, 1. The ostrich, has a bill somewhat conical; the wings are so short as to be unfit for flying; the thighs and sides of the body are naked; the feet are formed for running, having two toes, one only of which is furnished with a nail. The head and bill somewhat resemble those of a duck; and the neck may be likened to that of a swan, but that it is much longer; the legs and thighs resemble those of a hen, though the whole appearnce bears a strong resemblance to that of a camel. But though usually seven feet high from the top of the head to the ground, from the back it is only four; so that the head and neck are above three feet long. From the top of the head to the rump, when the neck is stretched out in a right line, it is six feet long, and the tail is about a foot more. One of the wings without the feathers, is a foot and a half; and being stretched out, with the feathers, is three feet.

The plumage is much alike in all; that is, generally black and white; though some of them are said to be grey. There are no feathers on the sides, nor yet on the thighs, nor under the wings. The lower part of the neck, about half-way, is covered with still smaller feathers than those on the belly and back; and those also are of different colours.

At the end of each wing there is a kind of spur almost like the quill of a porcupine. It is an inch long, being hollow and of a horny substance. There are two of these on each wing; the largest of which is at the extremity of the bone of the wing, and the other a foot lower. The neck seems to be more slender in proportion to that of other birds, from its not being furnished with feathers. The skin in this part is of a livid flesh-colour, which some improperly would have to be blue. The bill is short and pointed, and two inches and a half at the beginning. The external form of the eye is like that of a man, the upper eye-lid being adorned with eye-lashes which are longer than those on the lid below. The tongue is small, very short, and composed of cartilages, ligaments, and membranes, intermixed with fleshy fibres. In some it is about an inch long, and very thick at the bottom; in others it is but half an inch, being a little forked at the end.

The ostrich is a native only of the torrid regions of Africa, and has long been celebrated by those who have had occasion to mention the animals of that region. Its flesh is proscribed in scripture as unfit to be eaten; and most of the antient writers describe it as well known in their times. Like the race of the elephant, it is transmitted down without mixture; and has never been known to breed out of that country which first produced it. It seems formed to live among the sandy and burning deserts of the torrid zone; and, as in some measure it owes its birth to their genial influence, so it seldom migrates into tracts more mild or more fertile. The Arabians assert that the ostrich never drinks; and the place of its habitation seems to confirm the assertion. In these formidable regions ostriches are seen in large flocks, which to the distant spectator appear like a regiment of cavalry, and have often alarmed a whole caravan. There is no desert, how barren soever, but what is capable of supplying these animals with provision; they eat almost every thing; and these barren tracts are thus doubly grateful, as they afford both food and security. The ostrich is very voracious. It will devour leather, grass, hair, iron, stones, or any thing that is given. Those substances which the coats of the stomach cannot soften, pass whole; so that glass, stones, or iron, are excluded in the form in which they were devoured.

In their native deserts, however, it is probable they live chiefly upon vegetables, where they lead an inoffensive and social life; the male, as Thevenot assures us, assorting with the female with connubial fidelity. They are said to be very much inclined to venery; and the make of the parts in both sexes seems to confirm the report. It is probable also they copulate like other birds, by compression. They lay very large eggs, some of them being above five inches in diameter, and weighing above fifteen pounds. These eggs have a very hard shell, somewhat resembling those of the crocodile, except that those of the latter are less and rounder.

The season for laying depends on the climate where the animal is bred. In the northern parts of Africa, this season is about the beginning of July; in the south it is about the latter end of December. These birds are very prolific, and lay generally from forty to fifty eggs at one clutch. It has been commonly reported, that the female deposits them in the sand, and covering them up, leaves them to be hatched by the heat of the climate, and then permits the young to shift for themselves. Very little of this, however, is true: no bird has a stronger affection for her young than the ostrich, nor none watches her eggs with greater assiduity. It happens, indeed, in those hot climates, that there is less necessity for the continual incubation of the female; and she more frequently leaves her eggs, which are in no danger of being chilled by the weather: but though she sometimes forsakes them by day, she always carefully broods over them by night; and Kolben, who has seen great numbers of them at the Cape of Good Hope, affirms, that they sit on their eggs like other birds, and that the male and the female take this office by turns, as he had frequent opportunities of observing. Nor is it more true what is said of their forsaking their young after they are excluded the shell. On the contrary, the young ones are not even able to walk for several days after they are hatched. During this time the old ones are very assiduous in supplying them with grass, and very careful to defend them from danger; nay, they encounter every danger in their defence. The young, when brought forth, are of an ash-colour the first year, and are covered with feathers all over. But in time these feathers drop; and those parts which are covered assume a different and more becoming plumage.

The beauty of a part of this plumage, particularly the long feathers that compose the wings and tail, is the chief reason that man has been so active in pursuing this harmless bird to its deserts, and hunting it with no small degree of expence and labour. The antients used those plumes in their helmets; our military wear them in their hats; and the ladies made them an ornament in their dress. Those feathers which are plucked from the animal while alive are much more valued than those taken when dead, the latter being dry, light, and subject to be worm-eaten.

Besides the value of their plumage, some of the savage nations of Africa hunt them also for their flesh; which they consider as a dainty. They sometimes also breed these birds tame, to eat the young ones, of which the females are said to be the greatest delicacy. Even among the Europeans now, the eggs of the ostrich are said to be well tasted, and extremely nourishing; but they are too scarce to be fed upon, although a single egg is a sufficient entertainment for eight men.

As the spoils of the ostrich are thus valuable, it is not to be wondered at that man has become their most assiduous pursuer. For this purpose, the Arabians train up their best and fleetest horses, and hunt the ostrich still in view. Perhaps, of all varieties of the chase, this, though the most laborious, is yet the most entertaining. As soon as the hunter comes within sight of his prey, he puts on his horse with a gentle gallop, so as to keep the ostrich still in sight; yet not so as to terrify him from the plain into the mountains. Of all known animals, the ostrich is by far the swiftest in running; upon observing himself, therefore, pursued at a distance, he begins to run at first but gently; either insensible of his danger, or sure of escaping. Unfortunately for the silly creature, instead of going off in a direct line, he takes his course in circles; while the hunters still make a small course within, relieve each other, meet him at unexpected turns, and keep him thus still employed, still followed, for two or three days together. At last, spent with fatigue and famine, and finding all power of escape impossible, he endeavours to hide himself from those enemies he cannot avoid, and covers his head in the sand or the first thicket he meets. Sometimes, however, he attempts to face his pursuers; and though in general the most gentle animal in nature, when driven to desperation he defends himself with his beak, his wings, and his feet. Such is the force of his motion, that a man would be utterly unable to withstand him in the shock.

The Struthophagi have another method of taking this bird: they cover themselves with an ostrich's skin, and passing up an arm through the neck, thus counterfeit all the motions of this animal. By this artifice they approach the ostrich, which becomes an easy prey. He is sometimes also taken by dogs and nets; but the most usual way is that mentioned above.

When the Arabians have thus taken an ostrich they cut its throat; and making a ligament below the opening, they shake the bird as one would rinse a barrel; then taking off the ligature, there runs out from the wound in the throat a considerable quantity of blood mixed with the fat of the animal; and this is considered as one of their greatest dainties. They next flay the bird; and of the skin, which is strong and thick, sometimes make a kind of vest, which answers the purposes of a cuirass and a buckler.

There are others who, more compassionate or more provident, do not kill their captive, but endeavour to tame it, for the purposes of supplying those feathers which are in so great request. The inhabitants of Daara and Lybia breed up whole flocks of them, and they are tamed with very little trouble. But it is not for their feathers alone that they are prized in this domestic state; they are often ridden upon and used as horses. Moore assures us, that at Joar, he saw a man travelling upon an ostrich; and Adanson asserts, that at the factory of Podore he had two ostriches, which were then young, the strongest of which ran swifter than the best English racer, although he carried two negroes on his back. As soon as the animal perceived that it was thus loaded, it set off running with all its force, and made several circuits round the village; till at length people were obliged to stop it by barring up the way. How far this strength and swiftness may be useful to mankind, even in a polished state, is a matter that perhaps deserves inquiry. See Plate Nat. Hist. fig. 379.

2. The cassowary (the casuarius of Linnæus, and galeated cassowary of Dr. Latham) was first brought into Europe from Java by the Dutch about the year 1597. It is nearly equal in size to the ostrich, but its legs are much thicker and stronger in proportion. This conformation gives it an air of strength and force, which the fierceness and singularity of its countenance conspire to render formidable. It is five feet and a half long from the point of the bill to the extremity of the claws. The legs are two feet and a half high from the belly to the end of the claws. The head and neck together are a foot and a half; and the largest toe, including the claw, is five inches long. The claw alone of the least toe is three inches and a half in length. The wing is so small that it does not appear, it being hidden under the feathers of the back. In other birds, a part of the feathers serve for flight, and are different from those that serve merely for covering; but in the cassowary all the feathers are of the same kind, and outwardly of the same colour. They are generally double, having two long shafts, which grow out of a short one, which is fixed in the skin. Those that are double are always of unequal length; for some are fourteen inches long, particularly on the rump, while others are not above three. The beards that adorn the stem or shaft are about half-way to the end, very long, and as thick as a horse-hair, without being subdivided into fibres. The stem or shaft is flat, shining, black, and knotted below; and from each knot there proceeds a beard; likewise the beards at the end of the large feathers are perfectly black, and towards the root of a grey tawny colour; shorter, more soft, and throwing out fine fibres like down; so that nothing appears except the ends, which are hard and black; because the other part, composed of down, is quite covered. There are feathers on the head and neck; but they are so short and thinly sown, that the bird's skin appears naked, except towards the hinder part of the head, where they are a little longer. The feathers which adorn the rump are extremely thick; but do not differ in other respects from the rest, except in their being longer. The wings, when they are deprived of their feathers, are but three inches long; and the feathers are like those on other parts of the body. The ends of the wings are adorned with five prickles, of different lengths and thickness, which bend like a bow: these are hollow from the roots to the very points, having only that slight substance within which all quills are known to have. The longest of these prickles is eleven inches; and it is a quarter of an inch in diameter at the root, being thicker there than towards the extremity: the point seems broken off.

The part, however, which most distinguishes this animal is the head; which, though small, like that of an ostrich, does not fail to inspire some degree of terror. It is bare of feathers, and is in a manner armed with a helmet of horny substance, that covers it from the root of the bill to near half the head backwards. This helmet is black before and yellow behind. Its substance is very hard, being formed by the elevation of the bone of the skull; and it consists of several plates one over another, like the horn of an ox. The neck is of a violet colour, inclining to that of slate; and it is red behind in several places, but chiefly in the middle. About the middle of the neck before, at the rise of the large feathers, there are two processes formed by the skin, which resemble somewhat the gills of a cock, but that they are blue as well as red. The skin which covers the fore part of the breast, on which this bird leans and rests, is hard, callous, and without feathers.

The same degree of voraciousness which we perceived in the ostrich obtains as strongly here. The cassowary swallows every thing that comes within the capacity of its gullet. The Dutch assert, that it can devour not only glass, iron, and stones, but even live on burning coals, without testifying the smallest fear of feeling the least injury. It is said, that the passage of the food through its gullet is performed so speedily, that even the very eggs which it has swallowed whole pass through it unbroken in the same form they went down. In fact, the alimentary canal of this animal, as was observed above, is extremely short; and it may happen, that many kinds of food are indigestible in its stomach, as wheat or currants are to a man when swallowed whole.

The cassowary's eggs are of a grey ash-colour, inclining to green. They are not so large nor so round, as those of the ostrich. They are marked with a number of little tubercles of a deep green, and the shell is not very thick. The largest of these is found to be fifteen inches round one way, and about twelve the other.

The southern parts of the most eastern Indies seem to be the natural climate of the cassowary. His domain, if we may so call it, begins where that of the ostrich terminates. The latter has never been found beyond the Ganges; while the cassowary is never seen nearer than the islands of Bandana, Sumatra, Java, the Molucca islands, and the corresponding parts of the continent. Yet even here this animal seems not to have multiplied in any considerable degree, as we find one of the kings of Java making a present of one of these birds to the captain of a Dutch ship, considering it as a very great rarity.

The casuarius Novæ Hollandiæ, or New Holland cassowary, differs considerably from the common cassowary. It is a much larger bird, standing higher on its legs, and having the neck longer than in the common one. Total length seven feet two inches. The bill is not greatly different from that of the common cassowary; but the horny appendage or helmet on the top of the head in this species is totally wanting: the whole of the head and neck is also covered with feathers, except the throat and fore part of the neck about half-way, which are not so well feathered as the rest; whereas in the common cassowary the head and neck are bare and carunculated as in the turkey.

The plumage in general consists of a mixture of brown and grey, and the feathers are somewhat curled or bent at the ends in the natural state: the wings are so very short as to be totally useless for flight, and indeed are scarcely to be distinguished from the rest of the plumage, was it not for their standing out a little. The long spines which are seen in the wings of the common sort are in this not observable, nor is there any appearance of a tail. The legs are stout, formed much as in the galeated cassowary, with the addition of their being jagged or sawed the whole of their length at the back part.

This bird is not uncommon in New Holland, as several of them have been seen about Botany-bay and other parts. Although it cannot fly, it runs so swiftly, that a greyhound can scarcely overtake it. The flesh is said to be in taste not unlike beef.

STRUTHIOLA, a genus of plants belonging to the class of tetrandria, and order of monogynia. The corolla is wanting; the calyx is tubulous, with eight glandules at its mouth; the berry is without juice, and monospermous. The species are 5, shrubs of the Cape.

STRYCHNOS, a genus of plants belonging to the class of pentandria, and order of monogynia; and in the natural system ranging under the twenty-eighth order, luridæ. The corolla is quinquefid; the berry is unilocular, with a woody bark. The species are three, the nux vomica, colubrina, and potatorum, natives of foreign countries.

STUARTIA, a genus of plants belonging to the class of monadelphia, and order of polyandria; and in the natural system ranging under the 37th order, columniferæ. The calyx is simple; the style is simple, with a quinquefid stigma; the apple is without juice, quinquelobed, monospermous, bursting open with a spring five ways. There are two species, foreign plants.

STUCCO, in building, a composition of white marble pulverised, and mixed with plaister of lime; and the whole being sifted and wrought up with water, is to be used like common plaister: this is called by Pliny marmoratum opus, and albarium opus.

STUM, in the wine trade, denotes the unfermented juice of the grape, after it has been several times racked off, and separated from its sediment.

STURGEON. See ACCIPENSER.

STURNUS, the *starling*, a genus of birds belonging to the order of passeres. The beak is subulated, depressed, and somewhat blunt; the superior mandible is entire, and somewhat open at the edges; the nostrils are marginated above; and the tongue is sharp and emarginated. There are 15 species, according to Dr. Latham; the vulgaris, capensis, ludovicianus, militaris, cellaris, carunculatus, gallinaceus, sericeus, viridis, olivaceus, moritanicus, loyca, dauricus, junceti, and mexicanus.

The vulgaris, or common starling, is the only species of the sturnus that is indigenous. The weight of the male of this species is about three ounces; that of the female rather less. The length is eight inches three quarters. The whole plumage is black, very resplendent, with changeable blue, purple, and copper: each feather marked with a pale yellow spot. The lesser coverts are edged with yellow, and slightly glossed with green.

The stare breeds in hollow trees, eaves of houses, towers, ruins, cliffs, and often in high rocks over the sea, such as that of the Isle of Wight. It lays four or five eggs, of a pale-greenish ash-colour; and makes its nest of straw, small fibres of roots, &c. In winter, stares assemble in vast flocks: they collect in myriads in the fens of Lincolnshire, and do great damage to the fen-men by roosting on the reeds, and breaking them down by their weight; for reeds are the thatch of the country, and are laid up in harvest with great care. These birds feed on worms and insects; and it is said they will get into pigeon-houses, for the sake of sucking the eggs. Their flesh is so bitter as to be scarcely eatable. They are fond of following oxen and other large cattle, as they feed in the meadows, attracted, as it is said, by the insects which flutter round them, or by those, perhaps, which swarm in their dung, or in meadows in general. From this habit is derived the German name rinder staren. They live seven or eight years, or even longer, in the domestic state. The wild ones cannot be decoyed by the call, because they regard not the scream of the owl. A method has been discovered of taking entire families, by fixing to the walls and the trees where they lodge, pots of earthenware of a convenient form, which the birds often prefer to place their nests in. Many are also caught by the gin and draw-net.

The stare, it is said, can be taught to speak either French, German, Latin, Greek, &c. and to pronounce phrases of some length. Its pliant throat accommodates itself to every inflection and every accent. It can readily articulate the letter R, and acquires a sort of warbling which is much superior to its native song. This bird is spread through an extensive range in the antient continent.

The sturnus cinclus, see Plate Nat. Hist. fig. 380, inhabits Europe and the northern parts of Persia; frequents waters, and feeds on aquatic insects and small fishes. It is very solitary, and breeds in the holes of banks; makes a very curious nest of hay and roots, lined with dead leaves, and having an entrance of green moss.

STYLE, a word of various significations, originally derived from ϛυλος, a kind of bodkin, wherewith the antients wrote on plates of lead, or on wax, &c. and which is still used to write on ivory leaves, and paper prepared for that purpose, &c.

STYLE. See DIALLING.

STYLE. See BOTANY.

STYLE, in matters of language. See RHETORIC, and POETRY.

STYLEPHORUS, a genus of fishes of the order apodes. The generic character is, eyes pedunculated, standing on a short thick cylinder; snout lengthened, directed upwards, retractile towards the head by means of a membrane; mouth without teeth; branchiæ three pair beneath the throat; fins, pectoral small, dorsal the length of the back, caudal short, with spiny rays; body very long, compressed. This highly singular genus was first described in the year 1788, from a specimen then introduced into the Leverian Museum, and figured in the first volume of the Linnæan Transactions, see Plate Nat. Hist. fig. 381.

Chordated stylephorus. The head of this extraordinary animal bears some distant resemblance to that of the genus syngnathus, and its structure cannot so easily be described in words as conceived by the figure. The rostrum or narrow part, which is terminated by the mouth, is connected to the back part of the head by a flexible leathery duplicature, which permits it to be either extended in such a manner that the mouth points directly upwards, or to fall back, so as to be received into a sort of case formed by the upper part of the head. On the top of the head are placed the eyes, which are of a form very nearly approaching to those of the genus cancer; except that the columns or parts on which eye is placed are much broader and thicker than in that genus; they are also placed close to each other; and the outward surface of the eye, when magnified, does not shew the least appearance of a reticulated structure. Below the head, on each side, is a considerable compressed semicircular space, the fore part of which is bounded by the covering of the gills, which covering seems to consist of a single membrane, of a moderately strong nature. Beneath this, on each side, are three small pair of branchiæ. The body is extremely long, and compressed very much, and gradually diminishes as it approaches the tail, which terminates in a string or process of an enormous length, and finishes in a very fine point. This string, or caudal process, seems to be strengthened throughout its whole length, or at least as far as the eye can trace it, by a sort of double fibre or internal part. The pectoral fins are very small, and situated almost immediately behind the cavity on each side the thorax. The general colour of this fish is a rich silver, except on the flexible part belonging to the rostrum, which is of a deep brown: the fins and caudal process are also brown. There is no appearance of scales on this fish.

STYLITES, an appellation given to a kind of solitaries, who spent their lives seated on the tops of columns, to be, as they imagined, the better disposed for meditation, &c. Of these we find several mentioned in antient writers, and even as low as the eleventh century. The founder of the order was St. Simon Stylites, a famous anchoret in the fifth century, who took up his abode on a column six cubits high; then on a second of twelve cubits; a third, of twenty-two; and, at last, on another of thirty-six. The extremity of these columns was only three feet in diameter, with a kind of rail or ledge about it that reached almost to the girdle, somewhat resembling a pulpit. There was no lying down in it. The faquirs, or devout people of the East, imitate this extraordinary kind of life even to this day.

STYLO-CERALOIDES, STYLO-Glossus, Stylo-*Hyoidæus*, Stylo-*Pharyngæus*, STYLOIDES, the names of different muscles in the human body. See Anatomy.

STYPTIC. See Pharmacy.

STYRAX. See Resins.

Styrax, the *storax-tree*, a genus of plants belonging to the class of decandria, and to the order of monogynia, and in the natural system ranging under the 18th order, bicornes. The calyx is inferior; corolla funnel-form; drupe two-seeded. Linnæus only mentions one species of this genus, the styrax officinale; but Aiton, in his Hortus Kewensis, has added two more; namely, the grandefolium, and lævigatum; and a fourth may now be added, the styrax benzoin.

The officinale usually rises about twenty feet in height; it sends off many strong branches, which are covered with a roughish bark of a grey colour: the leaves are broad, elliptical, entire, somewhat pointed, on the upper surface smooth, and of a light-green colour, on the under surface covered with a whitish down; they are placed alternately, and stand upon short footstalks: the flowers are large, white, and disposed in clusters upon short peduncles, which terminate the branches: the corolla is monopetalous; the fruit is a pulpy pericarpium.

The resinous drug called storax issues in a fluid state from incisions made in the trunk or branches of the tree. Two sorts of this resin have been commonly distinguished in the shops: 1. Storax in the tear, is scarcely, if ever, found in separate tears, but in masses, sometimes composed of whitish and pale reddish brown tears, and sometimes of an uniform reddish yellow or brownish appearance; unctuous and soft like wax, and free from visible impurities. This is supposed to be the sort which the antients received from Pamphylia in reeds or canes, and which was thence named calamita.

2. Common storax: in large masses, considerably lighter and less compact than the former, and having a large admixture of woody matter like saw-dust. This appears to be the kind intended by the London college, as they direct their styrax calamita to be purified, for medicinal use, by softening it with boiling water, and pressing it out from the feces betwixt warm ironplates: a process which the first does not stand in need of; and indeed there is rarely any other than this impure storax to be met with in the shops.

Storax, with some of the antients, was a familiar remedy as a resolvent, and particularly used in catarrhal complaints, coughs, asthmas, menstrual obstructions, &c. and from its affinity to the balsams, it was also prescribed in ulcerations of the lungs, and other states of pulmonary consumption. And our pharmacopœias formerly directed the pilulæ e styrace; but this odoriferous drug has now no place in any of the officinal compounds; and though a medicine which might seem to promise some efficacy in nervous debilities, yet by modern practitioners it is almost totally disregarded.

The styrax benzoin, see Plate Nat. Hist. fig. 382, has been characterised by oblong acuminated leaves, which are downy underneath, and nearly of the length of the racemi.

This tree, which is a native of Sumatra, is deemed in six years of sufficient age for affording the benzoin, or when its trunk acquires about seven or eight inches in diameter; the bark is then cut through longitudinally, or somewhat obliquely, at the origin of the principal lower branches, from which the drug exudes in a liquid state, and by exposure to the sun and air soon concretes, when it is scraped off from the bark with a knife or chisel. The quantity of benzoin which one tree affords never exceeds three pounds, nor are the trees found to sustain the effects of these annual incisions longer than ten or twelve years. The benzoin which issues first from the wounded bark is the purest, being soft, extremely fragrant, and very white; that which is less esteemed is of a brownish colour, very hard, and mixed with various impurities, which it acquires during its long continuance upon the trees.

The benzoin which we find here in the shops is in large brittle masses, composed partly of white, partly of yellowish or light-brown, and often also of darker-coloured pieces; that which is clearest, and contains the most white matter, called by authors benzoe amygdaloides, is accounted the best. This resin has very little taste, impressing on the palate only a slight sweetness: its smell, especially when rubbed or heated, is extremely fragrant and agreeable. It totally dissolves in rectified spirit (the impurities excepted, which are generally in a very small quantity) into a deep yellowish-red liquor, and in this state discovers a degree of warmth and pungency, as well as sweetness. It imparts, by digestion, to water also a considerable share of its fragrance, and a slight pungency: the filtred liquor, gently exhaled, leaves not a resinous or mucilaginous extract, but a crystalline matter, seemingly of a saline nature, amounting to one-tenth or one-eighth of the weight of the benzoin. Exposed to the fire in proper vessels, it yields a quantity of a white saline concrete, called flores benzoes, of an acidulous taste and grateful odour, soluble in rectified spirit, and in water by the assistance of heat.

The principal use of this fragrant resin is in perfumes, and as a cosmetic; for which last purpose, a solution of it in spirit of wine is mixed with so much water as is sufficient to render it milky, as twenty times its quantity or more. It promises, however, to be applicable to other uses, and to approach in virtue, as in fragrance, to storax, and balsam of tolu. It is said to be of great service in disorders of the breast, for resolving obstructions of the pulmonary vessels, and promoting expectoration: in which intentions the flowers are sometimes given from three or four grains to fifteen. The white powder, precipitated by water from solutions of the benzoin in spirit, has been employed by some as similar and superior to the flowers, but appears to be little other than the pure benzoin in substance: it is not the saline, but the resinous matter of the benzoin, that is most disposed to be precipitated from spirit by water. The flowers, snuffed up the nose, are said to be a powerful errhine.

SUBALTERN, a subordinate officer, or one who discharges his post under the command and subject to the direction of another: such are lieutenants, sub-lieutenants, cornets and ensigns, who serve under the captain; but custom has now appropriated the term to those of much lower ranks, as serjeants, &c. We also say subaltern courts, jurisdictions, &c. such are those of inferior lords, with regard to the lord paramount; hundred-courts with regard to county-courts, &c.

SUBCLAVIAN. See Anatomy.

SUBCOSTAL MUSCLES. See Anatomy.

SUBDUPLE RATIO, is when any number or quantity is contained in another twice: thus 3 is said to be subduple of 6, as 6 is duple of 3.

SUBDUPLICATE RATIO of any two quantities, is the ratio of their square roots.

SUBER. This name has been introduced into chemistry by Fourcroy, to denote the outer bark of the quercus suber, or the common cork, a substance which possesses properties different from all other vegetable bodies.

It is exceedingly light, soft, and elastic; very combustible, burning with a bright white flame, and leaving a light black bulky charcoal; and when distilled it yields a little ammonia. Nitric acid gives it a yellow colour, corrodes, dissolves, and decomposes it, converting it partly into suberic acid, partly into a substance resembling wax.

SUBERATS, salt formed with the suberic acid, which see.

SUBERIC ACID may be formed by pouring six parts of nitric acid of the specific gravity 1.261 on one part of cork grated down or simply broken down into small pieces, and distilling the mixture with a gentle heat as long as red vapours continue to escape. As the distillation advances, a yellow matter like wax makes its appearance on the surface of the liquid. While the matter contained in the retort is hot, it is to be poured into a glass vessel, placed upon a sand-bath over a gentle fire, and constantly stirred with a glass rod. By this means it becomes gradually thick. As soon as white vapours, exciting a tickling in the throat, begin to disengage themselves, the vessel is removed from the bath, and the mass continually stirred till it is almost cold.

By this means an orange-coloured mass is obtained of the consistence of honey, of a strong and sharp odour while hot, but having a peculiar aromatic smell when cold.

On this mass twice its weight of boiling water is to be poured, and heat applied till it becomes liquid; and then that part of it which is insoluble in water is to be separated by filtration. The filtred liquor becomes muddy; on cooling it deposits a powdery sediment, and a thin pellicle forms on its surface. The sediment is to be separated by filtration, and the liquor reduced to a dry mass by evaporating in a gentle heat. This mass is suberic acid. It is still a little coloured, owing to some accidental mixture, from which it may be purified either by saturating it with potass and precipitating it by means of an acid, or by boiling it along with charcoal-powder.

Suberic acid thus obtained is not crystallizable, but when precipitated from potass by an acid it assumes the form of a powder: when obtained by evaporation it forms thin irregular pellicles.

Its taste is acid and slightly bitter; and when dissolved in a small quantity of boiling water it acts upon the throat, and excites coughing.

It reddens vegetable blues; and when dropped into a solution of indigo in sulphuric acid (liquid blue, as it is called in this country), it changes the colour of the solution, and renders it green.

Water at the temperature of 60° or even 70° dissolves only $\frac{1}{576}$ part of its weight of suberic acid; and if the acid is very pure, only $\frac{1}{144}$th part: boiling water, on the contrary, dissolves half its weight of it.

When exposed to the air, it attracts moisture, especially if it is impure.

When exposed to the light of day, it becomes at last brown; and this effect is produced much sooner by the direct rays of the sun.

When heated in a matrass, the acid sublimes, and the inside of the glass is surrounded with zones of different colours. If the sublimation is stopped at the proper time, the acid is obtained on the sides of the vessel in small points formed of concentric circles. When exposed to the heat of the blowpipe on a spoon of platinum, it first melts, then becomes pulverulent, and at last sublimes entirely with a smell resembling that of sebacic acid.

It is not altered by oxygen gas: the othe acids do not dissolve it completely. Alcoho developes an aromatic odour, and an ether may be obtained by means of this acid.

It converts the blue colour of nitrat of copper to a green; the sulphat of copper also to a green; green sulphat of iron to a deep yellow; and sulphat of zinc to a golden yellow.

It has no action either on platinum, gold, or nickel; but it oxidizes silver, mercury, copper, lead, tin, iron, bismuth, arsenic, cobalt, zinc, antimony, manganese, and molybdenum.

With alkalies, earths, and metallic oxides, it forms compounds known by the name of suberats.

Its affinities are as follows:

Barytes,
Potass,
Soda,
Lime,
Ammonia,
Magnesia,
Alumina.

SUBLIMATION, a process by which certain volatile substances are raised by heat, and again condensed by cold in a solid form. Flowers of sulphur are made in this way. Soot is also an instance of sublimation. See CHEMISTRY.

SUBNORMAL, in geometry, is a line which determines the point in the axis of a curve, where a normal, or perpendicular, raised from the point or contact of a tangent to the curve, cuts the axis. Or the subnormal is a line which determines the point wherein the axis is cut by a line falling perpendicularly on the tangent in the point of the contact.

SUBPŒNA, is a writ by which all persons under the degree of peerage are called into chancery, in such case only where the common law fails, and has made no provisions; so as the party who in equity has wrong, can have no other remedy by the rules and course of common law. But the peers of the realm in such cases are called by the lord chancellor's, or lord keeper's letters, giving notice of the suit intended against them, and requiring them to appear. There is also a subpœna ad testificandum for the summoning of witnesses as well in chancery as other courts.

There is also a subpœna in the exchequer, as well in the court of equity there, as in the office of pleas.

SUBROGATION, or SURROGATION, in the civil law, the act of substituting a person in the place, and entitling him to the rights, of another; but, in its general sense, subrogation implies a succession of any kind, whether of a person to a person, or of a person to a thing. There are two kinds of subrogation, the one conventional, the other legal. Conventional subrogation is a contract, whereby a creditor transfers his debt, with all appurtenances thereof, to the profit of a third person. Legal subrogation is that which the law makes, in favour of a person who discharges an antecedent creditor, in which case there is a legal translation of all rights of the antient creditor to the person of the new one. This the civilians more usually call succession, as being wholly the work of the law; and to distinguish it from the conventional subrogation, which they also call cession.

SUBSIDY, in law, signifies an aid or tax granted to the king, by parliament, for the necessary occasions of the kingdom; and is to be levied on every subject of ability, according to the rate or value of his lands or goods: but this word, in some of our statutes, is confounded with that of customs.

SUBSISTENCE, in the military art, is the money paid to the soldiers weekly, not amounting to their full pay; because their clothes, accoutrements, tents, bread, &c. are to be paid. It is likewise the money paid to officers upon account, till their accounts are made up, which is generally once a year, and then they are paid their arrears.

SUBSTITUTION, in the civil law, a disposition of a testament, whereby the testator substitutes one heir for another, who has only the usufruit, and not the property of the thing left him. Substitution is only a kind of fiduciary inheritance, called also fidei commissio, in regard the immediate inheritor has only the use or produce of the thing; the body thereof being substituted and appropriated to certain persons, who are likewise to have the usufruit in their turns, but are never to have the property.

SUBSTITUTION, in algebra, &c. is the putting, in the room of any quantity in an equation, some other quantity, which is equal to it, but expressed in another manner.

SUBTANGENT *of a curve*, in the higher geometry, is the line which determines the intersection of the tangent with the axis; or, that determines the point wherein the tangent cuts the axis prolonged.

In any equation, if the value of the subtangent comes out positive, it is a sign that the points of intersection of the tangent and axis fall on that side of the ordinate where the vertex of the curve line lies, as in the parabola and paraboloids: but if it comes out negative, the point of intersection will fall on the contrary side of the ordinate, in respect of the vertex, or beginning of the abscissa; as in the hyperbola and hyperboliform figures. And universally, in all paraboliform and hyperboliform figures, the subtangent is equal to the exponent of the power of the ordinate, multiplied into the abscissa.

If CB is an ordinate to AB, in any given angle, terminating in any curve AC, and AB $= x$, BC $= y$, and the relation between x and y, that is, the nature of the curve, is expressed by this equation, $x^3 - 2xxy + bxx - bbx + byy - y^3 = 0$; then this will be the rule of drawing a tangent to it: multiply the terms of the equation by an arithmetical progression; suppose, according to the dimensions of y,

$$\begin{matrix} x^3 & - 2xxy & + bxx & - bbx & + byy & - y^3; \\ 0 & 1 & 0 & 0 & 2 & 3 \end{matrix}$$

as also according to the dimensions of x, as

$$\begin{matrix} x^3 & - 2xxy & + bxx & - bbx & + byy & - y^3: \\ 3 & 2 & 2 & 1 & 0 & 0 \end{matrix}$$

the former product shall be the numerator, and the latter, divided by x, the denominator, of a fraction expressing the length of the subtangent; which, in this case, will be

$$= \frac{-2xxy + 2byy - 3y^3}{3xx - 4xy + 2bx - bb}.$$

SUBTENSE, in geometry, the same with the chord of an arch. See CHORD.

Hence, the subtense of an angle is a right line supposed to be drawn between the two extremities of the arch that measures that angle.

SUBTRACTION. See ARITHMETIC, and ALGEBRA.

SUBULARIA, *rough-leaved alysson*, or *awlwort*, a genus of plants belonging to the class of tetradynamia, and order of siliculosa; and in the natural order ranking under the 39th order, siliquosæ. The silicula is entire and ovate; the valves are ovate, concave, and contrary to the partitions. The style is shorter than the silicula. There is only one species, the aquatica, which is a native of Britain.

SUBULATED. See BOTANY.

SUCCINATS, salts formed with the succinic acid, which see.

SUCCINIC ACID. Amber is a well-known brown, transparent, inflammable body, pretty hard, and susceptible of polish, found at some depth in the earth, and on the sea-coast of several countries. It was in high estimation among the antients both as an ornament and a medicine. When this substance is distilled, a volatile salt is obtained, which is mentioned by Agricola under the name of salt of amber; but its nature was long unknown. Boyle was the first who discovered that it was an acid. From succinum, the Latin name of amber, this acid has received the appellation of succinic acid.

1. It is obtained by the following process: Fill a retort half-way with powdered amber, and cover the powder with a quantity of dry sand; lute on a receiver, and distil in a sand-bath without employing too much heat. There passes over first an insipid phlegm; then a weak acid, which, according to Scheele, is the acetic; then the succinic acid attaches itself to the neck of the retort; and if the distillation is continued, there comes over at last a thick brown oil, which has an acid taste.

The succinic acid is at first mixed with a quantity of oil. It may be made tolerably pure by dissolving it in hot water, and putting upon the filtre a little cotton, previously moistened with oil of amber: this substance retains most of the oil, and allows the solution to pass clear. The acid is then to be crystallized by a gentle evaporation; and this process is to be repeated till the acid is sufficiently pure. Guyton Morveau has discovered that it may be made quite pure by distilling off it a sufficient quantity of nitric acid, taking care not to employ a heat strong enough to sublime the succinic acid.

2. The crystals of succinic acid are transparent, white, shining, and of a foliated triangular, prismatic form: they have an acid taste, but are not corrosive: they redden tincture of turnsole, but have little effect on that of violets.

They sublime when exposed to a considerable heat, but not at the heat of a water-bath. In a sand-bath they melt, and then sublime and condense in the upper part of the vessel; but the coal which remains shews that they are partly decomposed.

3. One part of this acid dissolves in 96 parts of water at the temperature of 50°, according to Spielman; in 24 parts at the temperature of 52°; and in two parts of water at the temperature of 212°, according to Stockar de Neuforn; but the greatest part crystallizes as the water cools. According to Roux, however, it still retains more of the acid than cold water is capable of dissolving.

Two hundred and forty grains of boiling alcohol dissolve 177 of this acid; but crystals again shoot as the solution cools.

4. The compounds which this acid forms with alkalies, acids, and metallic oxides, have received the name of succinats. Scarcely any of them have been examined with attention.

5. When combined with soda, it crystallizes in four and six-sided prisms. When this salt is distilled in a retort, the succinic acid is completely decomposed. There pass over into the receiver an acid liquor, which is the acetic much diluted, and a quantity of brown oil. At the same time carbonic acid gas, and carbureted hydrogen gas, are disengaged, and there remain in the retort soda and charcoal. Hence it follows that this acid, like the others of the same class, is decomposed by heat, and that it is composed of oxygen, hydrogen, and carbon.

6. The affinities of succinic acid, according to Morveau, are as follows:

Barytes,
Lime,
Potass,
Soda,
Ammonia,
Magnesia,
Alumina,
Metallic oxides.

SUCCINUM. See AMBER.

SUDORIFIC. See MATERIA MEDICA.

SUFFERANCE. Tenant at sufferance is he who holds over his term at first lawfully granted. A person is tenant at sufferance who continues after his estate is ended, and wrongfully holds against another, &c. 1 Co. Inst. 57.

Tenants holding over, after determination of their term, and after demand made in writing to deliver possession, are rendered liable to pay double the yearly value. And tenants giving notice of their intention to quit, and not accordingly delivering up the possession at the time in such notice contained, are rendered liable to pay double rent. And it has been held, that under this act, the notice need not be in writing, and that the landlord may levy his double rent by distress. Bur. 1603.

SUGAR, which at present forms so important an article in our food, seems to have been known at a very early period to the inhabitants of India and China. But Europe probably owes its acquaintance with it to the conquests of Alexander the Great. For ages after its introduction into the West, it was used only as a medicine; but its consumption gradually increased: and during the time of the crusades, the Venetians, who brought it from the East, and distributed it to the northern parts of Europe, carried on a lucrative commerce with sugar. It was not till after the discovery of America, and the extensive cultivation of sugar in the West Indies, that its use in Europe, as an article of food, became general.

Sugar was formerly manufactured in the southern parts of Europe; but at present almost all our sugar comes from the East and West Indies. The plant from which it is procured is the saccharum officinarum (see SACCHARUM), or sugar-cane. Other plants indeed contain it, but not in such abundance. In North America, however, it is extracted from the acer saccharinum, or sugar-maple. Attempts have been lately made to extract it from the beet.

1. The method of making sugar practised in Indostan is exceedingly simple, and requires little or no expensive apparatus. The soil chosen is a rich vegetable mould, in such a situation that it can be easily watered from a river. About the end of May, when the soil is reduced to the state of soft mud either by rain or artificial watering, slips of the cane, containing one or two joints, are planted in rows about four feet from row to row, and eighteen inches asunder in the rows. When they have grown to the height of two or three inches, the earth round them is loosened. In August small trenches are cut through the field to drain off the rain, if the season proves too rainy, and to water the plants if the season proves too dry. From three to six canes spring from each slip set. When they are about three feet high, the lower leaves of each cane are carefully wrapt round it; and then the whole belonging to each slip are tied to a strong bamboo eight or ten feet high, and stuck into the earth in the middle of them. They are cut in January and February, about 9 months after the time of planting. They have now reached the height of eight or ten feet, and the naked cane is from an inch to an inch and a quarter in diameter. They have not flowered. When this happens, the juice loses much of its sweetness. The canes are now put through the rollers of a mill, and their juice collected into large iron boilers; where it is boiled down smartly to a proper consistence, the scum being carelessly taken off. The fire is then withdrawn, and the liquid by cooling becomes thick. It is then stirred about with sticks till it begins to take the form of sugar; when it is put in mats made of the leaves of the palmira-tree (borassus flabelliformis), and the stirring continued till it is cold. This process yields a raw or powdered sugar; but it is clammy, and apt to attract moisture from the atmosphere, because the acids in the juice have not been removed. By the addition of quicklime to the juice, in the proportion of about three spoonfuls to every 14 gallons, the sugar loses this property. The impure sugar prepared by this method is called jagary. Every three quarts of juice, or every six pounds, yields about one pound of sugar. From an acre of ground about 5000 pounds of sugar, and consequently about 30,000 pounds of juice, are obtained.

2. In the West India islands the raising of sugar is much more expensive, and the produce much less, owing to the high price of labour; or, which is the same thing, to the nature of the labourers, and to the inferiority of the soil. The juice is put into large boilers, mixed with quicklime, and boiled to a proper consistency; the scum in the mean time being carefully taken off. When it ceases to be ropy, it is drawn off into another vessel, where it is allowed to concrete, and the liquid and impure part called molasses to separate from it. The more completely this separation is allowed to be, the finer is the sugar. The sugar thus obtained is in small hard grains of a brownish-white colour, and is imported to Europe under the name of raw sugar.

3. In North America the farmers procure sugar for their own use by a still simpler pro-

cess, from the sap of the acer saccharinum, or sugar maple-tree, which abounds in the woods. (See Acer.) Every forty pounds of sap yields about a pound of sugar; so that it is not one sixth so rich as the East India sugar-cane.

The sap ought never to be kept longer than twenty-four hours after it is procured from the tree. It is improved by straining through a cloth. It is put into large flat kettles, mixed usually with quicklime, white of egg, and new milk. A spoonful of slacked lime, the white of one egg, and a pint of new milk, are sufficient for fifteen gallons of sap. A little butter is added to prevent the sap from boiling over. When boiled down sufficiently, it is allowed to grain, or form into small crystals, which constitute raw sugar, and then purified in the usual manner.

4. The raw sugar imported into Europe is still farther purified. It is dissolved in water, mixed with lime, clarified by means of bullock's blood, boiled down to a proper consistency, skimming off the impurities as they rise to the top, and then poured into unglazed conical earthen vessels, where it is allowed to grain. The point of the cone is undermost, and perforated to allow the impurities to separate. The base of the cone is covered with moist clay; the water of which gradually filtres through the sugar, and displaces a quantity of impure liquid. The sugar thus purified is called loaf-sugar. When redissolved, and treated in the same way a second time, it it called refined sugar.

5. Sugar, thus procured, has a very strong sweet taste. When pure it has no smell. Its colour is white; and when crystallized it is somewhat transparent. It has often a considerable degree of hardness: but it is always so brittle that it can be reduced without difficulty to a very fine powder. When two pieces of sugar are rubbed against each other in the dark, a strong phosphorescence is visible.

Sugar is not altered by exposure to the atmosphere, excepting only that in damp air it absorbs a little moisture.

It is exceedingly soluble in water. At the temperature of 48°, water, according to Mr. Wenzel, dissolves its own weight of sugar. The solvent power of water increases with its temperature; when nearly at the boiling point, it is capable of dissolving any quantity of sugar whatever. Water thus saturated with sugar is known by the name of syrup.

Syrup is thick, ropy, and very adhesive; when spread thin upon paper it soon dries, and forms a kind of varnish, which is easily removed by water. Its specific caloric, according to the experiments of Dr. Crawford, is 1.086. When syrup is sufficiently concentrated, the sugar which it contains precipitates in crystals. The primitive form of these crystals is a four-sided prism, whose base is a rhomb, the length of which is to its breadth as 10 to 7; and whose height is a mean proportion between length and breadth of the base. The crystals are usually four or six-sided prisms, terminated by two-sided, and sometimes by three-sided summits. The specific gravity of sugar is 1.4045.

When heat is applied to sugar it melts, swells, becomes brownish black, emits air-bubbles, and exhales a peculiar smell, known in French by the name of caromel. At a red heat it instantly bursts into flames with a kind of explosion. The colour of the flame is white with blue edges.

6. Sugar, as far as is known, is not acted upon by oxygen gas. The effect of the simple combustibles on it has not been tried; but it does not appear to be great. Azotic gas or the metals have no sensible actions on it.

The lower compartment of Plate Saw-mill, &c. represents a mill for squeezing the juice from the sugar-canes. ABDE is a strong frame of wood, the lower part D of which is a large block: the upper surface of this is cut out into a bason, to collect and receive the juice of the canes; which is expressed by the three rollers FGH, whose lower pivots work in sockets in the block D, and the upper sockets are fixed in the beam E. The sockets of the middle roller are fixed firmly in the beams D and E. The sockets of the other two are held between two wedges *ab*, put in in contrary directions, the small end of one wedge being on the same side with the large end of the other. By this means the rollers can always be set nearer together, or farther from each other. When it is wanted to set the outside rollers nearer the middle roller, drive out that wedge which is nearest the middle roller, and drive the other in; and the contrary when they are wanted farther apart. The rollers are usually of cast iron, and each has a cog-wheel, as I, on its upper end, which causes them all to turn together, the power of the first mover being applied to the middle one by a shaft K.

When the machine is at work, a man stands on each side of it. The one in the front takes the canes, and puts them in between the rollers FG, which, as they turn, draw the canes through, and express their juice. The man behind them directs the ends of the canes back between the rollers GH, which are somewhat nearer together than the others; and as they come through, a third man carries them away. The juice runs down the rollers into the reservoir, and is conveyed by the trough L to the boiling-house. It must be observed, that the reservoir in the top of the block D must be only cut in channels round the outside of the rollers; being left the full height near the centres, to prevent the liquor running down, and getting out between the wedges *ab*.

When a sugar-mill is worked by wind, the shaft K is connected with the vertical shaft of the mill. If by horses, the levers they work from are fixed to the shaft K; and either the horse-walk is raised above ground higher than the trough L, or the juice is conveyed by a pipe laid under the walk.

Sugar-mills that are worked by a water-wheel, or steam-engine, have a bevelled wheel fixed upon the shaft K, and another upon the wheel or engine shaft which turns it.

The earths proper do not seem to have any action whatever on sugar; but the alkaline earths unite with it. When lime is added to a solution of sugar in water, and the mixture boiled for some time, a combination takes place. The liquid still indeed retains its sweet taste; but it has acquired also a bitter and astringent one. A little alcohol added to the solution produced a precipitate in white flakes, which appeared to be a compound of sugar and lime. Sulphuric acid precipitated the lime in the state of sulphat, and restored the original taste of the sugar. When the compound of sugar and lime was evaporated to dryness, a semitransparent tenacious syrup remained which had a rough bitter taste, with a certain degree of sweetness.

The fixed alkalies combine with sugar, and form compounds, not unlike that which has been just described. Potass destroys the sweet taste of syrup more completely than lime; but when it is neutralized by sulphuric acid, and the sulphat precipitated by alcohol, the sweet taste is completely restored. When alcohol is agitated with the compound of sugar and potass dissolved in water, it refuses to unite with it, but swims on the top in a state of purity.

The acids are capable of dissolving sugar, and those which are concentrated decompose it. Sulphuric acid very soon acts upon it; water is formed, and perhaps also acetic acid; while charcoal is evolved in great abundance, and gives the mixture a black colour, and a considerable degree of consistency. The charcoal may be easily separated by dilution and filtration. When heat is applied, the sulphuric acid is rapidly converted into sulphureous acid.

Nitric acid dissolves it with an effervescence, occasioned by the evolution of nitrous gas, and converts it into malic and oxalic acids. 480 grains of sugar, treated with six ounces of nitric acid diluted with its own weight of water, and cautiously heated, separating the crystals as they formed, yielded 280 grains of oxalic acid; so that 100 parts of sugar yield by this treatment 58 parts of oxalic acid. When liquid oxymuriatic acid is poured upon sugar in powder, it is dissolved, and immediately converted into malic acid; and the oxymuriatic acid is converted into common muriatic acid.

Sugar absorbs muriatic acid gas slowly, and assumes a brown colour and very strong smell. The vegetable acids dissolve it; but seemingly without producing any alteration on it.

The action of the oxides of carbon and azote upon sugar has scarcely been examined.

Sugar is soluble in alcohol, but not in so large a proportion as in water. According to Wenzel, four parts of boiling alcohol dissolve one of sugar. It unites readily with oils, and renders them miscible with water. A moderate quantity of it prevents, or at least retards, the coagulation of milk; but Scheele discovered that a very large quantity of sugar causes milk to coagulate.

The hydrosulphurets, sulphurets, and phosphurets of alkalies and alkaline earths, seem to have the property of decomposing sugar, and of bringing it to a state not very different from that of gum. Mr. Cruickshank introduced a quantity of syrup into a jar standing over mercury, and then added about an equal quantity of phosphuret of lime. Phosphureted hydrogen gas was immediately extricated. In eight days the syrup was withdrawn: it had lost its sweet taste, and acquired a bitter and astringent one (the taste of phosphuret of lime). From this solution alcohol threw down white flakes, very much resembling those of mucilage separated from water by the same liquid. A little sugar was dissolved in alcohol, and phosphuret of lime added to it. No apparent action took place. The mixture, after standing in the open air for some days, was evaporated, and water added. No gas was disengaged, as the phosphuret had been converted into a phosphat. The liquid being filtred and evaporated, a tenacious substance remained, much resembling gum arabic. Its taste was bitter, with a slight degree of sweetness. It did not seem soluble in alcohol. It burned like gum.

7. When sugar is distilled in a retort, there comes over a fluid which at first scarcely differs from pure water; soon it is mixed with what was formerly called pyromucous acid, and is now known to be a compound of oil and acetic acid; afterwards some empyreumatic oil makes its appearance, and a bulky charcoal remains in the retort. This charcoal very frequently contains lime, because lime is used in refining sugar; but if the sugar, before being submitted to distillation, is dissolved in water, and made to crystallize by evaporation in a temperature scarcely higher than that of the atmosphere, no lime whatever, nor any thing else, except pure charcoal, will be found in the retort. During the distillation, there comes over a considerable quantity of carbonic acid and carbureted hydrogen gas. Sugar therefore is decomposed by the action of heat; and the following compounds are formed from it: water, acetic acid, oil, charcoal, carbonic acid, carbureted hydrogen gas. The quantity of oil in a separate state is inconsiderable; by far the most abundant product is pyromucous acid. Sugar indeed is very readily converted into pyromucous acid; for it makes its appearance always whenever syrup is raised to the boiling temperature. Hence the smell of caromel which syrup at that temperature emits. Hence also the reason, that, when we attempt to crystallize syrup by heat, there always remains behind a quantity of incrystallizable matter, known by the name of molasses: whereas if the syrup is crystallized without artificial heat, every particle of sugar may be obtained from it in a crystalline form. Hence we see the importance of properly regulating the fire during the crystallization of the sugar, and the saving that would probably result from conducting the operation at a low heat.

We are indebted to Mr. Cruikshank for the most precise set of experiments on the decomposition of sugar by heat. 480 grains of pure sugar were introduced into a coated retort, and heated gradually to redness. The products were

Pyromucous acid with a drop or two of oil	270	grains
Charcoal	120	
Carbureted hydrogen, and carbonic acid gas	90	
	480	

The pyromucous acid required about 75 grains of a solution of potass to saturate it; and when thus neutralized, no ammonia was disengaged. Hence sugar contains no azote, unless we suppose a very minute portion to be present in the pyromucous acid; and even this is not likely. The charcoal burns away without leaving any residue. Hence sugar contains no earth nor fixed alkali. The proportion of the gaseous products was 119 ounce-measures of carbureted hydrogen, and 41 ounce-measures of carbonic acid gas. The carbureted hydrogen, according to the experiments of Cruikshank, was composed of five parts carbon and one hydrogen.

These experiments are sufficient to shew us, that sugar is composed entirely of oxygen, carbon, and hydrogen. It is of course a vegetable oxide. Lavoisier has concluded, from a series of experiments on the vinous fermentation, that these substances enter into the composition of sugar in the following proportions:

64	oxygen
28	carbon
8	hydrogen
100.	

But these proportions can only be considered as very distant approximations to the truth.

8. From the experiments of different chemists, especially of Proust and Gottling, it appears that there are different species of sugar found ready-prepared in the vegetable kingdom; distinguished from each other by the figure of their crystals, and other variations in their properties. The species hitherto examined are three in number, namely, common sugar, sugar of grapes, and sugar of beet. As far as is known at present, there is no difference between the sugar of the maple and common sugar.

9. That grapes contain abundance of sugar has been long known. The Duc de Boullion first extracted it from the juice of grapes, and Proust pointed out the difference between it and common sugar. The juice of grapes, according to him, yielded from 30 to 40 per cent. of this sugar.

10. Margraf discovered sugar in the root of the beta vulgaris; but it is to Achard that we are indebted for the first attempts to extract it from that plant in a large way. The experiments of that philosopher, of Lampadius, of the committee appointed by the national institute, and of Goettling, have thrown more light on this interesting subject. The method which succeeded best with Achard, was to boil the beet-roots (deprived of the heart) till they became so soft as to be easily pierced by a straw. They are then cut into slices, and the juice forced out by pressure. What remains is left for twelve hours in water, and the whole subjected to the press a second time. The liquids thus obtained are filtered through flannel, boiled down to two-thirds, filtered a second time, reduced by boiling to one-third of the original liquid, filtered a third time, and then evaporated to the consistence of syrup. The crystalline crust which forms on the surface is to be broken from time to time, and the spontaneous evaporation continued till the surface becomes covered with a tough coat instead of crystals. The whole is then to be thrown into woollen bags, and the mucilaginous liquid separated from the crystals by pressure.

The sugar obtained by these processes, has much the appearance of raw sugar; but it may be refined by the common processes, and brought into the state of common sugar. From the experiments of Goettling, it appears that beet-sugar is distinguished by a certain degree of a nauseous bitter taste; owing, it is supposed, to the presence of a bitter extractive matter, which Lampadius has shewn to be one of the constituents of the beet.

11. The plants containing sugar are very numerous. The following are the chief of those from which it has been actually extracted by chemists:

The sap of the acer saccharinum,
——— betula alba,
——— asclepias syriaca,
——— heraclium sphondilium,
——— cocos nucifera,
——— juglans alba,
——— agave Americana,
——— fucus saccharinus,
——— ficus carica,
The juice of arundo saccharifera,
——— zea mays,
The roots of pastinaca sativa,
——— sium sisarum,
——— beta vulgaris and cicla,
——— daucus carota,
——— apium petroselinum.

Parmentier has also ascertained, that the grains of wheat, barley, &c. and all the other similar seeds which are used as food, contain at first a large quantity of sugar, which gradually disappears as they approach to a state of maturity. This is the case also with peas and beans, and all leguminous seeds: and is one reason why the flavour of young peas is so much superior to that of old ones.

SUIT, in law, is used in different senses, as, 1. Suit personal. 2. Suit of court, or suit service, is an attendance that tenants owe to the court of their lord. 3. Suit covenant, is where the ancestor has covenanted with another, to sue to his court. 4. Suit custom, when a man and his ancestors have been seized time out of mind, of his suit. 5. Suit real, or regal, when men come to the sheriff 's torn or leet. 6. Suit signifies the following one in chase, as fresh suit. 7. It signifies a petition made to the king or any great person. Cowel.

SUKOTYRO, a genus of quadrupeds of the order bruta; the generic character, horn on each side near the eyes. There is but a single species, viz. the indicus: mane upright, short, narrow, reaching from the top of the head to the rump. It inhabits Java, and feeds on herbs.

SULPHATS, salts formed with the sulphuric acid, which see.

SULPHITES, salts formed with the sulphurous acid, which see.

SULPHUR, distinguished also in English by the name of brimstone, was known in the earliest ages. As it is found native in many parts of the world, it could not fail very soon to attract the attention of mankind. It was used by the anticnts in medicine, and its fumes were employed in bleaching wool. See Pliny, Lib. xxxv. c. 15.

1. Sulphur is a hard brittle substance, commonly of a yellow colour, without any smell, and of a weak though perceptible taste.

It is a non-conductor of electricity, and of course becomes electric by friction. Its specific gravity is 1.990.

Sulphur undergoes no change by being allowed to remain exposed to the open air. When thrown into water, it does not melt as common salt does, but falls to the bottom, and remains there unchanged. It is therefore insoluble in water.

2. If a considerable piece of sulphur is exposed to a sudden though gentle heat, by holding it in the hand, for instance, it breaks to pieces with a crackling noise.

When sulphur is heated to the temperature of about 170°, it rises up in the form of a fine powder, which may easily be collected in a proper vessel. This powder is called flowers of sulphur. When substances fly off in this manner on the application of a moderate heat, they are called volatile; and the process itself, by which they are raised, is called volatilization.

When heated to the temperature of 212° of Fahrenheit's thermometer, it melts and becomes as liquid as water. If this experiment is made in a thin glass vessel, of an egg shape, and having a narrow mouth, the vessel may be placed upon burning coals without much risk of breaking it. The strong heat soon causes the sulphur to boil, and converts it into a brown-coloured vapour, which fills the vessel, and issues with considerable force out from its mouth.

3. Sulphur is capable of crystallizing, if it is melted, and as soon as its surface begins to congeal, and the liquid sulphur beneath is poured out, the internal cavity will exhibit long needle-shaped crystals of an octahedral figure. This method of crystallizing sulphur was contrived by Rouelle. If the experiment is made in a glass vessel, or upon a flat plate of iron, the crystals will be perceived beginning to shoot when the temperature sinks to 220°.

4. If sulphur is kept melted in an open vessel, it becomes gradually thick and viscid. When in this state, if it is poured into a bason of water, it will be found to be of a red colour, and as soft as wax. In this state it is employed to take off impressions from seals and medals. These casts are known in this country by the name of sulphurs. When exposed to the air for a few days, the sulphur soon recovers its original brittleness, but it retains its red colour. It is supposed at present, that sulphur, rendered viscid and red by long fusion, has combined with a little oxygen. It is therefore no longer pure sulphur, but a compound of sulphur and oxygen. Mr. Fourcroy has given it, when in this state, the name of oxide of sulphur.

5. When sulphur is heated to the temperature of 560° in the open air, it takes fire spontaneously, and burns with a pale blue flame, and at the same time emits a great quantity of fumes of a very strong suffocating odour. When set on fire and then plunged into a jar full of oxygen gas, it burns with a bright reddish white flame, and at the same time emits a vast quantity of fumes. If the heat is continued long enough, the sulphur burns all away without leaving any ashes or residuum. If the fumes are collected, they are found to consist entirely of sulphuric acid. By combustion, then, sulphur is converted into an acid.

The combustion of sulphur, in fact, is nothing else than the act of its combination with oxygen; and for any thing which we know to the contrary, it is a simple substance.

6. The affinities of sulphur, according to Bergman, are as follows:

Fixed Alkalies.

Iron,	Antimony,
Copper,	Mercury,
Tin,	Arsenic,
Lead,	Molybdenum,
Silver,	Bismuth.

SULPHURETS are combinations of alkalies or metals with sulphur.

SULPHURIC ACID is generally procured by burning a mixture of sulphur and nitre in chambers lined with lead. The theory of this process requires no explanation. The nitre supplies a quantity of oxygen to the sulphur, and the air of the atmosphere furnishes the rest. The acid thus obtained is not quite pure, containing a little potass, some lead, and perhaps also nitric and sulphurous acids. At first it is very weak, being diluted with the water necessary for condensing it; but it is made stronger by distilling off a portion of this water. By this process it is made quite transparent; but it still contains a little lead, which it dissolved from the vessels in which it was manufactured, and a little potass which it acquired from the nitre employed in burning the sulphur. To obtain it in a state of complete purity, the sulphuric acid of commerce must be distilled. This is easily done by putting it into a small retort with a long beak. The bottom of the retort is placed upon a fire of charcoal, and fixed steady by means of an iron ring; while its beak is plunged half-way into a receiver, whose mouth it fits nearly, but not exactly. The acid soon boils, and is gradually condensed in the receiver. Too great a quantity should not be distilled at once, otherwise the retort generally breaks in consequence of the violent agitation into which the boiling acid is thrown.

Sulphuric acid is a liquid somewhat of an oily consistence, transparent and colourless as water, without any smell, and of a very strong acid taste. When applied to animal or vegetable substances, it very soon destroys their texture.

It always contains a quantity of water; part of which, however, may be driven off by the application of a moderate heat. This is called concentrating the acid. When as much concentrated as possible, its specific gravity is said to be 2.000; but it can seldom be obtained denser than 1.85.

It changes all vegetable blues to a red except indigo. According to Erxleben, it boils at 546°; according to Bergman, at 540°.

When exposed to a sufficient degree of cold, it crystallizes or freezes; and after this has once taken place, it freezes again by the application of a much inferior cold. Sulphuric acid has a very strong attraction for water.

Mr. Lavoisier attempted to ascertain the proportion of the constituents of this acid, by measuring the quantity of oxygen absorbed by a given weight of sulphur during its combustion. His result was 71 parts of sulphur, and 29 of oxygen. But this method was not susceptible of sufficient precision to warrant much confidence. Mr. Thenard had recourse to a much better method, which was employed still more lately for the same purpose by Mr. Chenevix with much address. Nitric acid was distilled off 100 parts of pure sulphur repeatedly, till the whole sulphur was converted into an acid. The sulphuric acid, thus formed, was separated by means of barytes, with which it forms an insoluble compound. The 100 parts of sulphur, thus acidified, yielded 694 parts of dry sulphat of barytes. Hence 100 parts of sulphat of barytes contain 14.5 parts of sulphur. By another set of experiments, to be described hereafter, Mr. Chenevix ascertained, that 100 parts of sulphat of barytes contain 23.5 parts of sulphuric acid. Hence it follows that 23.5 parts of sulphuric acid contain 14.5 of sulphat; the remaining 9 parts must be oxygen. Therefore sulphuric acid is composed of 14.5 parts of sulphur and 9 of oxygen; or, which is the same thing, of

61.5	sulphur
38.5	oxygen
100.0	

Sulphuric acid is not altered by the action of light nor caloric. It does not combine with oxygen. It was affirmed, indeed, by some chemists, that sulphuric acid might be combined with oxygen by distilling it off the black oxide of manganese; but the assertion was refuted by the experiments of Vauquelin.

None of the simple combustibles act upon it at the usual temperature of the atmosphere, or at least, their action is so slow as not to be perceptible. But when they are assisted by heat, they are all capable of decomposing it.

When sulphur is boiled in this acid, it absorbs a portion of its oxygen, or at least combines with it, and the whole is converted into sulphurous acid. Phosphorus also absorbs oxygen from it by the assistance of heat, sulphurous acid is driven off, and phosphoric acid formed. At the boiling temperature charcoal also absorbs oxygen from it, and converts it into sulphurous acid. At a red heat it even converts it into sulphur. When hydrogen gas and sulphuric acid are made to pass together through a red-hot tube of porcelain, the acid is completely decomposed, water is formed, and sulphur deposited.

Azote has no action on sulphuric acid; but this acid readily absorbs muriatic acid, and forms with it a liquid of a brownish tinge, which emits the dense and suffocating odour of muriatic acid, and corrodes vegetable and even metallic bodies near which it happens to be placed.

When zinc or iron is thrown into sulphuric acid, a violent action takes place, if the acid is diluted; water is decomposed, its hydrogen flies off, and its oxygen combines with the metals. If the acid is concentrated, the action is much less violent, and sulphurous acid exhales. Upon tin and copper the acid acts very slowly and feebly, unless its action is assisted by heat, when it oxidizes and dissolves them. On silver, mercury, antimony, bismuth, arsenic, and tellurium, it does not act except at pretty high temperatures. These metals abstract part of its oxygen, and convert one portion of it into sulphurous acid, while another portion combines with the oxides thus formed. When boiling-hot it oxidizes lead, and dissolves cobalt, nickel, and molybdenum: but it has no perceptible action on gold or platinum at any temperature to which it can be raised.

It unites readily with all the alkalies and earths except silica, and with most of the metallic oxides, and forms salts denominated sulphats. Thus the combination of sulphuric acid and soda is called sulphat of soda; the compound of sulphuric acid and lime, sulphat of lime, &c.

It absorbs a very considerable quantity of nitrous gas, and acquires by that means a purplish colour.

Its affinities are as follows:

Barytes,	Ammonia,
Strontian,	Glucina,
Potass,	Yttria,
Soda,	Alumina,
Lime,	Zirconia,
Magnesia,	Metallic oxides.

This is one of the most important of all the acids, not only to the chemist but to the manufacturer also; being employed to a very great extent in a variety of manufactures, especially in dyeing.

Sulphurous acid. Though some of the properties of this acid must have been known in the remotest ages, as it is always formed during the slow combustion of sulphur, Stahl was the first chemist who examined it, and pointed out its peculiar nature. His method of procuring it was to burn sulphur at a low temperature, and expose to its flames cloth dipped in a solution of potass. By this method he obtained a combination of potass and sulphurous acid; for at a low temperature sulphur forms by combustion only sulphurous acid. Scheele pointed out, in 1771, a method of procuring sulphurons acid in quantities. Dr. Priestley, in 1774, obtained it in the gaseous form, and examined its properties while in a state of purity.

1. Sulphurous acid may be procured by the following process: Put into a glass retort two parts of sulphuric acid and one part of mercury, and apply the heat of a lamp; the mixture effervesces, and a gas issues from the beak of the retort, and may be received in glass jars filled with mercury, and standing in a mercurial trough. This gas is sulphurous acid.

2. Sulphurous acid, in the state of gas, is colourless and invisible like common air. It is incapable of maintaining combustion; nor can animals breathe it without death. It has a strong and suffocating odour, precisely the same with that exhaled by sulphur burning with a blue flame: sulphur, by such a combustion, being totally converted into a sulphurous acid. Its specific gravity, according to Bergman, is 0.00246; according to Lavoisier, 0.00251. It is therefore somewhat more than twice as heavy as air. One hundred cubic inches of it weigh nearly 63 grains.

3. This acid reddens vegetable blues, and gradually destroys the greater number of them. It exercises this power on a great variety of vegetable and animal colours. Hence the use of the fumes of sulphur in bleaching wool and in whitening linen stained by means of fruits.

4. Dr. Priestley discovered, that when a strong heat is applied to this acid in close vessels, a quantity of sulphur is precipitated, and the acid is converted into sulphuric. Berthollet obtained the same result; but Fourcroy and Vauquelin could not succeed.

5. Water absorbs this acid with avidity. According to Dr. Priestley, 1000 grains of water, at the temperature 54.5°, absorb 39.6 grains of this acid. Fourcroy, on the other hand, affirms that water at 40° absorbs the third of its weight of sulphurous acid gas. Ice absorbs this gas very rapidly, and is instantly melted. Water saturated with this gas, in which state it is known by the name of liquid sulphurous acid, or sulphurous acid, is of the specific gravity 1.040. It may be frozen without parting with any of the acid gas. When water, which has been saturated with this acid at the freezing temperature, is exposed to the heat of 65.25°, it is filled with a vast number of bubbles, which continually increase and rise to the surface. These bubbles are a part of the acid separating from it. It freezes a few degrees below 32°.

6. When liquid sulphurous acid is exposed to atmospheric air or to oxygen gas, it gradually combines with oxygen, and is converted into sulphuric acid. This change takes place more completely if the acid is combined with an alkali or earth. When a mixture of sulphurous acid gas and oxygen gas is made to pass through a red-hot porcelain tube, the two bodies combine, and sulphuric acid is formed.

7. Of the simple combustibles, sulphur and phosphorus have no action on it whatever; hydrogen gas and charcoal do not alter it while cold, but at a red-heat they decompose it completely; water or carbonic acid is formed, and sulphur deposited.

8. Neither azote nor muriatic acid produces any change on it.

9. Sulphurous acid does not seem capable of oxidizing or dissolving any of the metals except iron, zinc, and manganese.

10. It combines with alkalies, earths, and metallic oxides, and forms salts known by the name of sulphites.

11. Sulphuric acid absorbs this gas in considerable quantity. It acquires a yellowish-brown colour, a penetrating odour, and the property of smoking when exposed to the air. When this mixture is distilled, the first vapour which comes over, and which is a compound of the two acids, crystallizes in long white prisms. This singular compound, formerly known by the name of glacial sulphuric acid, smokes in the air; and when the atmosphere is moist, melts with effervescence. When thrown into water, it hisses like a red iron. It has the odour of sulphurous acid. Fourcroy has lately demonstrated, that this is a compound of sulphuric and sulphurous acids.

12. The affinities of sulphurous acid, as far as they have been investigated, are as follow:

Barytes,	Magnesia, }
Lime,	Ammonia, }
Potass,	Glucina,
Soda,	Alumina,
Strontian,	Zirconia.

13. As this acid is formed by the combustion of sulphur, it cannot be doubted that it is composed of the same ingredients with sulphuric acid; and as it is evolved from sulphuric acid by the action of sulphur, and likewise by some of the metals, it cannot be doubted that it contains a smaller proportion of oxygen. But no precise set of experiments has yet been made to determine the proportion of its component parts. Fourcroy affirms that it contains

85 sulphur
15 oxygen
———
100.

But he does not inform us upon what evidence he assigns these proportions.

SUM, in mathematics, signifies the quantity that arises from the addition of two or more magnitudes, numbers, or quantities together.

The sum of an equation is, when the absolute number being brought over to the other side of the equation, with a contrary sign, the whole becomes equal to 0; thus, the sum of the equation $x^3 - 12x^2 + 41x = 42$, is $x^3 - 12x^2 + 41x - 42 = 0$. See Algebra, and Arithmetic.

SUMACH. See Rhus.

SUN. See Astronomy.

SUNDAY. See Lord's Day.

SUPERCARGO, a person employed by merchants to go a voyage, and oversee their cargo, or lading, and dispose of it to the best advantage.

SUPERFICIES, or Surface. See Geometry.

SUPERSEDEAS, a writ that lies in a great many cases, and signifies in general, a command to stay proceedings, on good cause shewn, which ought otherwise to proceed. By a supersedeas, the doing of a thing, which might otherwise have been lawfully done, is prevented; or a thing that has been done, is (notwithstanding it was done in a due course of law) thereby made void. 4 Bac. Abr. 667.

A supersedeas is either expressed or implied; an express supersedeas is sometimes by writ, sometimes without a writ; where it is by writ, some person to whom the writ is directed, is thereby commanded to forbear the doing something therein mentioned; or if the thing has been already done, to revoke, as that can be done, the act. 4 Bac. Abr. 667.

SUPER STATUTO de articulis cleri, in law, a writ that lies against the sheriff, or other officer that distrains in the king's highway, or in the lands antiently given to the church.

Super statuto facto pour seneschal et marshal de roy, &c. a writ which lies against the steward or marshal, for holding plea of freehold in his court, or for trespass, or contracts not made within the king's household.

SUPPLIES, the sums granted by parliament for defraying the public expenditure for the current year. The known or probable amount of the different branches of the year's expences, is stated to the house of commons in a committee of supply, by the chancellor of the exchequer; and after they have been voted by the committee, are formally granted by an act of parliament. The granting of the annual supplies as well as permanent taxes, is a peculiar privilege of the house of commons, who never permit any alteration or amendment to be made by the lords, in the bills passed for this purpose.

The grants of parliament were originally considered, merely as temporary aids, to assist the sovereign in defraying such extraordinary expences as he was subject to for the benefit of the public; and unless the commons happened to entertain at the time, any particular jealousy of the crown and its ministers, the sum granted was commonly left entirely to their disposal. But after the restoration of Charles II., not only more frequent grants were demanded, but, in consequence of the property to which the crown was reduced, parliamentary grants had become really necessary almost every year. It was impossible, however, for the parliament, distrusting not only Charles's economy, but his regard for the interest of his kingdoms, to vest considerable sums of money in such unsafe and improvident hands: it was, therefore, thought requisite to specify the purposes for which each sum was voted. Thus appropriating clauses came to be introduced, which practice has continued ever since; and at the commencement of each session, an account is presented of the disposition of the grants of the preceding session, shewing how much has been actually paid on each branch of the public service, what remains unpaid of the sums appropriated, with the funds for discharging the same, and the surplus or deficiency of the ways and means.

The supplies annually voted do not include the interest and charges of the national debt, the civil list, and some other articles which are provided for as permanent charges on the consolidated fund; but merely the expences of the army, navy, ordnance, and such miscellaneous services as are granted from year to year.

SUPPORTERS. See HERALDRY.

SUPPRESSION. See MEDICINE.

SUPREMACY, in our polity, the superiority or sovereignty of the king over the church as well as state, whereof he is established head. The king's supremacy was at first established, or, as others say, recovered, by king Henry VIII. in 1534, after breaking with the pope. It is since confirmed by several canons, as well as by the articles of the church, and is passed into an oath which is required as a necessary qualification for all offices and employments both in church and state, from persons to be ordained, from the members of both houses of parliament, &c.

SURA. See ANATOMY.

SURD, in arithmetic and algebra, denotes any number or quantity that is incommensurable to unity: otherwise called an irrational number or quantity.

The square roots of all numbers, except 1, 4, 9, 16, 25, 36, 49, 64, 81, 100, 121, 144, &c. (which are the squares of the integer numbers, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, &c.) are incommensurables: and after the same manner the cube roots of all numbers but of the cubes of 1, 2, 3, 4, 5, 6, &c. are incommensurables: and quantities that are to one another in the proportion of such numbers, must also have their square-roots, or cube-roots, incommensurable.

The roots, therefore, of such numbers, being incommensurable, are expressed by placing the proper radical sign over them: thus $\sqrt[2]{2}$, $\sqrt[2]{3}$, $\sqrt[2]{5}$, $\sqrt[2]{6}$ &c. express numbers incommensurable with unity. However, though these numbers are incommensurable themselves with unity, yet they are commensurable in power with it; because their powers are integers, that is, multiples of unity. They may also be commensurable sometimes with one another, as the $\sqrt[2]{8}$, and $\sqrt[2]{2}$; because they are to one another as 2 to 1: and when they have a common measure, as $\sqrt[2]{2}$ is the common measure of both, then their ratio is reduced to an expression in the least terms, as that of commensurable quantities, by dividing them by their greatest common measure. This common measure is found as in commensurable quantities, only the root of the common measure is to be made their common divisor: thus $\frac{\sqrt{12}}{\sqrt{3}} = \sqrt{4} = 2$, and $\frac{\sqrt{18a}}{\sqrt{2}} = 3\sqrt{a}$.

A rational quantity may be reduced to the form of any given surd, by raising the quantity to the power that is denominated by the name of the surd, and then setting the radical sign over it; thus

$a = \sqrt[2]{a^2} = \sqrt[3]{a^3} = \sqrt[4]{a^4} = \sqrt[5]{a^5} = \sqrt[n]{a^n}$, and $4 = \sqrt{16} = \sqrt[3]{64} = \sqrt[4]{256} = \sqrt[5]{1024} = \sqrt[n]{4^n}$.

As surds may be considered as powers with fractional exponents, they are reduced to others of the same value that shall have the same radical sign, by reducing these fractional exponents to fractions having the same value and a common denominator. Thus $\sqrt[n]{a} = a^{\frac{1}{n}}$, and $\sqrt[m]{a} = a^{\frac{1}{m}}$, and $\frac{1}{n} = \frac{m}{nm}$, $\frac{1}{m} = \frac{n}{nm}$; and therefore, $\sqrt[n]{a}$ and $\sqrt[m]{a}$, reduced to the same radical sign, become $\sqrt[nm]{a^m}$ and $\sqrt[nm]{a^n}$. If you are to reduce $\sqrt[2]{3}$ and $\sqrt[3]{2}$ to the same denominator, consider $\sqrt[2]{3}$ as equal to $3^{\frac{1}{2}}$, and $\sqrt[3]{2}$ as equal to $2^{\frac{1}{3}}$, whose indices reduced to a common denominator, you have $3^{\frac{1}{2}} = 3^{\frac{3}{6}}$, and $2^{\frac{1}{3}} = 2^{\frac{2}{6}}$, and, consequently, $\sqrt[2]{3} = \sqrt[6]{3^3} = \sqrt[6]{27}$, and $\sqrt[3]{2} = \sqrt[6]{2^2} = \sqrt[6]{4}$; so that the proposed surds $\sqrt[2]{3}$ and $\sqrt[3]{2}$, are reduced to other equal surds $\sqrt[6]{27}$ and $\sqrt[6]{4}$, having a common radical sign.

Surds of the same rational quantity are multiplied by adding their exponents, and divided by subtracting them; thus, $\sqrt[2]{a} \times \sqrt[3]{a} = a^{\frac{1}{2}} \times a^{\frac{1}{3}} = a^{\frac{3+2}{6}} = a^{\frac{5}{6}} = \sqrt[6]{a^5}$; and $\frac{\sqrt[3]{a}}{\sqrt[5]{a}} = \frac{a^{\frac{1}{3}}}{a^{\frac{1}{5}}} = a^{\frac{1}{3} - \frac{1}{5}} = a^{\frac{5-3}{15}} = a^{\frac{2}{15}} = \sqrt[15]{a^2}$; $\sqrt[m]{a} \times \sqrt[n]{a} = a^{\frac{m+n}{mn}}$; $\frac{\sqrt[m]{a}}{\sqrt[n]{a}} = a^{\frac{n-m}{mn}}$; $\sqrt[2]{2} \times \sqrt[3]{2} = \sqrt[6]{2^5} = \sqrt[6]{3^2}$; $\frac{\sqrt[2]{2}}{\sqrt[3]{2}} = \sqrt[6]{2}$.

If the surds are of different rational quantities, as $\sqrt[n]{a^2}$ and $\sqrt[n]{b^3}$, and have the same sign, multiply these rational quantities into one another, or divide them by one another, and set the common radical sign over their product or quotient. Thus, $\sqrt[n]{a^2} \times \sqrt[n]{b^3} = \sqrt[n]{a^2b^3}$; $\sqrt[2]{2} \times \sqrt[2]{5} = \sqrt[2]{10}$; $\frac{\sqrt[m]{a^4}}{\sqrt[m]{b^3a}} = \sqrt[m]{\frac{a^4}{b^3a}} = \sqrt[m]{\frac{a^3}{b^3}}$; $\frac{\sqrt[3]{9}}{\sqrt[3]{24}} = \sqrt[3]{\frac{9}{24}} = \sqrt[3]{\frac{3}{8}} = \frac{1}{2}\sqrt[3]{3}$.

If surds have not the same radical sign, reduce them to such as shall have the same radical sign, and proceed as before; $\sqrt[m]{a} \times \sqrt[n]{b} = \sqrt[nm]{a^n b^m}$; $\frac{\sqrt[m]{a}}{\sqrt[n]{x}} = \sqrt[mn]{\frac{a^n}{x^m}}$; $\sqrt[2]{2} \times \sqrt[3]{4} = 2^{\frac{1}{2}} \times 4^{\frac{1}{3}} = 2^{\frac{3}{6}} \times 4^{\frac{2}{6}} = \sqrt[6]{2^3 \times 4^2} = \sqrt[6]{8 \times 16} = \sqrt[6]{128}$; $\frac{\sqrt[3]{4}}{\sqrt[2]{2}} = \frac{4^{\frac{1}{3}}}{2^{\frac{1}{2}}} = \frac{4^{\frac{2}{6}}}{2^{\frac{3}{6}}} = \sqrt[6]{\frac{4^2}{2^3}} = \sqrt[6]{\frac{16}{8}} = \sqrt[6]{2}$. If the surds have any rational co-efficients, their product or quotient must be prefixed; thus, $2\sqrt[2]{3} \times 5\sqrt[2]{6} = 10\sqrt[2]{18}$. The powers of surds are found as the powers of their quantities, by multiplying their exponents by the index of the power required; thus the square of $\sqrt[3]{2}$ is $2^{\frac{1}{3} \times 2} = 2^{\frac{2}{3}} = \sqrt[2]{4}$; the cube of $\sqrt[2]{5} = 5^{\frac{1}{2} \times 3} = 5^{\frac{3}{2}} = \sqrt[2]{125}$. Or you need only, in involving surds, raise the quantity under the radical sign to the power required, continuing the same radical sign; unless the index of that power is equal to the name of the surd, or a multiple of it, and in that case the power of the surd becomes rational. Evolution is performed by dividing the fraction, which is the exponent of the surd, by the name of the root required. Thus the square root of $\sqrt[3]{a^4}$ is $\sqrt[3]{a^2}$, or $\sqrt[6]{a^4}$.

The surd $\sqrt[m]{a^m x} = a\sqrt[m]{x}$; and, in like manner, if a power of any quantity of the same name with the surd divides the quantity under the radical sign without a remainder, as here a^m divides $a^m x$, and 25 the square of 5 divides 75, the quantity under the sign in $\sqrt[2]{75}$, without a remainder; then place the root of that power rationally before the sign, and the quotient under the sign, and thus the surd will be reduced to a more simple expression. Thus $\sqrt[2]{75} = 5\sqrt{3}$; $\sqrt[2]{48} = \sqrt[2]{3 \times 16} = 4\sqrt[2]{3}$; $\sqrt[3]{81} = \sqrt[3]{27 \times 3} = 3\sqrt[3]{3}$.

When surds are reduced to their least expressions, if they have the same irrational part, they are added or subtracted, by adding or subtracting their rational co-efficients, and prefixing the sum or difference to the common irrational part. Thus,

$\sqrt[2]{75} + \sqrt[2]{48} = 5\sqrt{3} + 4\sqrt{3} = 9\sqrt{3}$;

$\sqrt[3]{81} + \sqrt[3]{24} = 3\sqrt[3]{3} + 2\sqrt[3]{3} = 5\sqrt[3]{3}$;

$\sqrt[2]{150} - \sqrt[2]{54} = 5\sqrt{6} - 3\sqrt{6} = 2\sqrt{6}$;

$\sqrt{a^2x} + \sqrt{b^2x} = a\sqrt{x} + b\sqrt{x} = \overline{a+b} \times \sqrt{x}$.

Compound surds are such as consist of two or more joined together; the simple surds are commensurable in power, and by being multiplied into themselves, give at length rational quantities; yet compound surds multiplied into themselves, commonly give still irrational products. But, when any compound surd is proposed, there is another compound surd which, multiplied into it, gives a rational product. Thus, if $\sqrt{a} + \sqrt{b}$ were proposed, multiplying it by $\sqrt{a} - \sqrt{b}$, the product will be $a - b$.

The investigation of that surd, which, multiplied into the proposed surd, gives a rational product, is made easy by three theorems, delivered by Mr. Maclaurin, in his Algebra, p. 109, seq. to which we refer the curious.

This operation is of use in reducing surd expressions to more simple forms. Thus, suppose a binominal surd divided by another, as $\sqrt[2]{20} + \sqrt[2]{12}$, by $\sqrt[2]{5} - \sqrt[2]{3}$, the quotient might be expressed by $\frac{\sqrt{20} + \sqrt{12}}{\sqrt{5} - \sqrt{3}}$. But this might be expressed in a more simple form, by multiplying both numerator and denominator by that surd which, multiplied into the denominator, gives a rational product: thus,

$$\frac{\sqrt{20}+\sqrt{12}}{\sqrt{5}-\sqrt{3}}=\frac{\sqrt{20}+\sqrt{12}}{\sqrt{5}-\sqrt{3}}\times\frac{\sqrt{5}+\sqrt{3}}{\sqrt{5}+\sqrt{3}}=$$

$$\frac{\sqrt{100}+2\sqrt{60}+6}{5-3}=\frac{16+2\sqrt{60}}{2}=8+$$

$2\sqrt{15}$. To do this generally, see Maclaurin, lib. cit. p. 113.

When the square root of a surd is required, it may be found, nearly, by extracting the root of a rational quantity that approximates to its value. Thus to find the square root of $3+2\sqrt{2}$, first calculate $\sqrt{2}=1{,}41421$. Hence $3+2\sqrt{2}=5{,}82842$, the root of which is found to be nearly 2,41421.

In like manner we may proceed with any other proposed root. And if the index of the root, proposed to be extracted, is great, a table of logarithms may be used. Thus $\sqrt[7]{5+\sqrt[13]{17}}$ may be most conveniently found by logarithms.

Take the logarithm of 17, divide it by 13; find the number corresponding to the quotient; add this number to 5; find the logarithm of the sum, and divide it by 7, and the number corresponding to this quotient will be nearly equal to $\sqrt[7]{5+\sqrt[13]{17}}$.

But it is sometimes requisite to express the roots of surds exactly by other surds. Thus, in the first example, the square root of $3+2\sqrt{2}$ is $1+\sqrt{2}$: for $\overline{1+\sqrt{2}}\times\overline{1+\sqrt{2}}=1+2\sqrt{2}+2=3+2\sqrt{2}$. For the method of performing this, the curious may consult Mr. Maclaurin's Algebra, where also rules for trinomials, &c. may be found.

SURETY, in law, generally signifies the same with bail. See Bail.

SURETY *of the peace*. A justice of the peace may, according to his discretion, bind all those to keep the peace, who in his presence shall make any affray, or shall threaten to kill or beat any person, or shall contend together in hot words; and all those who shall go about with unlawful weapons or attendance to the terror of the people; and all such persons as shall be known by him to be common barrators; and all who shall be brought before him by a constable, for a breach of the peace in the presence of such constable; and all such persons who, having been before bound to keep the peace, shall be convicted of having forfeited their recognizance. Lamb, 77.

When surety of the peace is granted by the court of king's bench, if a supersedeas comes from the court of chancery to the justices of that court, their power is at an end; and the party as to them discharged.

If security of the peace is desired against a peer, the safest way is to apply to the court of chancery, or king's bench. 1 Haw. 127. If the person against whom security of the peace is demanded, is present, the justice of the peace may commit him immediately, unless he offers sureties; and a fortiori he may be commanded to find sureties, and be committed for not doing it. Id.

Surety *of the good behaviour*, includes the peace; and he that is bound to the good behaviour, is therein also bound to the peace; and yet a man may be compelled to find sureties both for the good behaviour and the peace. Dalt. c. 122. See Good Behaviour.

SURFEIT. See Medicine.

SURGERY, is the art of curing or alleviating diseases by local and external applications, manual or instrumental. As a science it may be defined, that department of medicine which treats of maladies thus susceptible of alleviation or cure.

This, like other parts of medicine, must necessarily have been practised in the earliest ages; and the supposition has the authority of history, both sacred and profane, that the whole of the healing art was for some time restricted to the treatment of external injuries; and that consequently, surgery has not merely been coeval with, but antecedent to, the other branches of medical science.

The history, however, of surgery, among the early Asiatics, and even as cultivated and practised by the Greeks, is involved in fable, and obscured by fiction. Hippocrates was in a manner the founder of surgery as of medicine; and it was not indeed until after the time of this author, that the science was divided into separate branches. This division was effected in the time of Ptolemy Philopater, king of Egypt, and has continued with some modifications, but without precise limits, down to the present day.

Among the Romans, Celsus is the first author, in whose writings we meet with any thing of importance in relation to this art. In the works of Celsus, we find a minute statement of all its improvements, from the time of Hippocrates; and by many among even the moderns, an assiduous study of the precepts contained in Celsus, has been earnestly recommended to the student. The Latinity, however, of this medical classic, is greatly preferable to his surgery.

After Celsus, lived the celebrated Galen, whose authority for so long a period influenced the language and practice of physic, and who, although his works are principally medicinal, wrote likewise on surgery. Galen was the last writer of consequence among the Romans.

About the year 500, Aetius added many observations to those of Celsus and Galen. Aetius was succeeded and much excelled by Paulus Egineta, whose surgical writings have been pronounced superior to those of all the other antients; this last author, together with Celsus, were employed as text-books by Fabricius ab Aquapendente, a writer of celebrity in the sixteenth century.

Among the Arabians, Rhazes and Avicenna are the principal writers who treated of surgery. The Canon Medicinæ of the latter, a compilation principally from Galen and Rhazes, was for a number of years held in much estimation. It was not, however, until the time of Albucasis, that surgery was much in repute among the Arabians; and from this period to the 14th century, its history is extremely barren. Even at the commencement of the 16th century, "surgery was held in contempt in this island, and was practised indiscriminately by barbers, farriers, and sow-gelders. Barbers and surgeons continued for 200 years afterwards to be incorporated in one company, both in London and Paris. In Holland and some parts of Germany, even at this day, barbers exercise the razor and lancet alternately."

We find no surgical work worthy of notice in the 16th century, before that of Carpus. A system published by the above-mentioned Fabricius, shortly afterwards attracted much notice, and has been highly commended by Boerhaave; about this time likewise, Ambrose Parée, a French surgeon, made several bold and very important innovations in the art as then practised; one of which, viz. the use of the needle and ligature, for stopping bleeding arteries, in place of the cautery, astringents, styptics, boiling oils, and other cruel and absurd practices of the older surgeons, has been said by one well capable of appreciating its value, to have raised Parée to a rank not inferior even to that of Harvey, the discoverer of the circulation. To the works of Parée may be added those of Maggius and Botallus, writers on gun-shot wounds; and of Cruce, the author of a systematic treatise.

In the succeeding century, surgery made considerable advances. The most conspicuous writers of this period, are Severinus, Vidius, Wiseman, Le Clerc, Scultetus, Mangetus, Spigellius, Hildanus, Bartholin, and Marchett.

In our own times, the science of which we are now to treat, has begun to assert its just claims to an equality with that which is usually denominated the science of medicine. These claims have been vindicated, not less powerfully and successfully by the importance of surgery, than the respectability of its professors.

A mere enumeration, however, of the names and writings of such as have been deservedly celebrated in the present and immediately preceding centuries, would carry us beyond our limits. We shall, therefore, here close this hasty sketch of surgical history, and proceed to discuss the subject of the present article.

Of Wounds. *Their kind, degree, and treatment.*

It ought to be the surgeon's endeavour to familiarize himself with those circumstances which immediately indicate the mortality of a wound; and this aptitude of discrimination is more especially requisite in the practice of the army or navy, where a speedy and irrevocable decision is frequently called for. The mortality of wounds is, indeed, often evident to the most superficial and uninitiated observer; but this is by no means invariably the case: and there are many instances, in which a prompt and accurate judgment respecting their consequences, immediate and remote, can only be formed by habits of reflective observation, grounded on a thorough knowledge of the anatomy, and a general acquaintance with the functions, of the body.

Wounds which penetrate the cavity of the heart; those which cut off the communication of vital organs with the brain, as injuries done to the medulla oblongata, or spinal marrow; of the small vessels which circulate within the brain; of the nerves supplying the heart; of the great receptacle of the chyle, or those which interrupt the course of this fluid to the blood-vessels, such as wounds of the larger lacteals, &c. may easily be admitted to rank with very little exception among mortal wounds; such are from their nature irremediable; others, however, although almost as surely fatal if neglected, may, by speedy and appropriate application, be often remedied; such as wounds of any of the larger blood-vessels, which are situated externally. But it is principally as it relates to wounds of the two great cavities of the chest and belly, that a speedy decision of their nature and tendency requires a knowledge of the anatomy, structure, relative connections, and functions, of the parts concerned; for the sword or the bullet may, by the smallest difference in its direction, occasion instantaneous death; give rise to tedious, intractable, and ultimately fatal diseases; or penetrate and even pass through the body, almost with impunity.

Wounds of the breast and lungs. Extreme difficulty of breathing, coughing up of blood, a discharge of air from its exterior orifice, or the sudden formation of emphysema or windy tumour, &c. are described by authors, among the signs indicating a wound in the lungs' substance. If, together with these symptoms, "the patient is oppressed, tossing, insensible; his face ghastly, and his extremities cold; his condition is doubtful; it looks much like a wound of some vessel near the root of the lungs, and if so, he is surely gone. If the oppression comes on more slowly, the pulse only hurried and fluttering, and the extremities not so cold, there is reason to hope that the wound is merely in the edges of the lungs; and as it is at a distance from the great veins and arteries, he may escape." (J. Bell on Wounds.) If, when the breast is wounded, there is no emphysema, no spitting of blood; none of that oppression in breathing, which proves that the blood is pouring either into the proper air-cells of the lungs, or the cellular texture of these organs, it may be concluded, that the wounding instrument has not passed into the thoracic cavity, but is merely in the external part of the chest. To ascertain whether the suffocative oppression just noticed, proceeds from extravasation of blood into the air-cells, or merely into the thoracic cavity, we are directed, that the finger be thrust into the wound, and some blood let out; which operation, if it is attended with very sensible relief, proves, that the air-cells or proper cavity of the lungs are uninjured; and the danger in this last case, is much less than if these cells had been wounded.

Wounds of the belly. Wounds of the belly are for the most part mortal; and this, when it does not arise from an injury to any of the large viscera or their great blood-vessels, principally depends upon the extreme susceptibility to peritonæal inflammation. "Wounds of the head are deadly, from the oppression of the brain, and there delirium or coma are the deadly signs. Wounds of the breast are fatal by the oppression of the lungs; and there difficult breathing, tossing, coughing of blood, coldness of the extremities, and a faultering, pulse are the mortal signs. Wounds of the abdomen are mortal by the inflammation and gangrene; and the signs of danger are, swelling of the abdomen, intense pain, vomitings, costiveness, hiccup, faintings; then an interval of deceitful ease, which is merely a sign of intellectual gangrene, and of the near approach of death. The wounding instrument, however, may penetrate or pass through the liver or the spleen, and prove mortal in another way beside that of inducing peritonæal inflammation; viz. by occasioning a sudden and copious extravasation of blood, and in these last cases the fatal symptoms present themselves with more rapidity. "In wounds of the liver, there is great inward bleeding: the patient immediately sinks, and faints, languishes in a slumbering state, insensible almost and without pain, lies cold and death-like for perhaps twenty-four hours, and then expires."

When the spleen or vena cava is wounded, the signs and consequences of the internal bleeding are nearly the same as in wounds of the liver. "A wound," says Mr. J. Bell, "of the spleen, liver, or vena cava, is as deadly as a wound of the heart, so full are they of blood." To this rule, however, there are some very few exceptions.

The inward bleedings from smaller vessels, as of the mesentery, the kidney, the emulgent veins, &c. for the most part prove mortal, in the secondary manner above alluded to, viz. by inducing inflammation; in these last instances then, the progress and nature of the symptoms are different. "And here it may be noticed, that if there are immediate fainting on receiving the wound, and then coldness, accompanied with a continued faintness, swelling of the belly, and oppressed breathing, most likely there is blood extravasated, and in dangerous quantity, from some greater vessel; but if the patient has lain easy, and there come pain, swelling, fever, and other threatening signs on the sixth or seventh day, with a tumour in one part of the belly, it is most likely a bloody tumour, which has begun to excite inflammation. If there are pain and swelling on the first or second day, it is from wounded intestine; if there are pain and swelling, but not till the sixth day, it is from blood; if there is no pain nor swelling till after the fifteenth day, our patient is almost safe."

When the stomach is wounded, a burning sensation is experienced at the pit of this organ, then follow heat, thirst, an accelerated pulse, and violent vomiting, which are succeeded by fainting, extreme prostration of the vital powers, an extremely rapid and fluttering pulse, swelling of the abdomen, hiccup, and death.

If the wound is in the intestines, the fæces often escape from the orifice; fever, pain, irritable pulse, swelling of the belly, faintings, mortification, and death, ensue.

We have hitherto spoken of peritonæal inflammation, as occasioned by an extravasation of blood; frequently, however, the irritating cause by which it is induced, consists of the contents of the viscus or viscera, that may be wounded. Thus, when the gall-bladder is the seat of the injury, the bile is poured out; when the urinary bladder is wounded, the urine; when the stomach, the food; and when the intestines, the fæces are discharged, and excite this fatal inflammation.

It is scarcely necessary to add, that beside the symptoms already enumerated, jaundice will almost invariably be attendant upon a wound of the gall-bladder or ducts; and an incontinence or suppression of urine, of the urinary bladder.

Further, a large wound penetrating the cavity of the belly is generally attended with a protrusion of some of the viscera; and even when the wound does not penetrate the abdominal cavity, the peritonæum sometimes protrudes and occasions hernia. Wounds likewise of the belly, which do not pierce the cavity of the abdomen, often prove distressing, tedious, and ultimately fatal, by occasioning sinuous ulcers among the muscles, and caries of the bones, and hectic fever. This is frequently the case in gun-shot wounds where, the bullet being lodged about the loins and in the heart of the muscles, the patient may have escaped the first danger, but will at length, after many months, be the victim of tedious suppuration, and lingering wasting hectic.

Respecting the symptoms which succeed to injuries of the head, we shall defer our remarks till we come to notice the surgical operations on the skull; and shall now go on to consider the treatment of wounds.

Treatment of wounds. It will first be necessary to consider the management of what are called simple wounds, without supposing the injury to have extended to the internal organs; to state the circumstances which may interfere with the orderly course of healing of such wound: and then to notice the more particular treatment of wounds in the breast or belly.

In conducting the cure of simple wounds, the surgeon will find "his duties happily reduced within the narrowest bounds, viz. of saving the patient from immediate bleeding, and of laying the wounded parts so clearly, so neatly, and so evenly in contact with each other, that they may adhere. The rest we leave to nature." "I fear," says the author from whom we have taken the above extract, "that from my announcing a rule of conduct so simple as this is, you will suppose, that I mean to speak only of the slighter and more trivial wounds; while I do really mean to include, under this general view, the greatest and the smallest wounds; and to establish but one rule for all, from the amputation of a limb, or the extirpation of a tumour, to the most trivial cut of the cheek or hand.

"What is amputation but a wound? the greatest wound, clean and fair, made carefully by the hand of the surgeon, disposed to heal in the easiest way? and in this great wound, which a fortiori includes the doctrine of every lesser wound, what is there to attend to but the procuring of adhesion, or the stopping of the flow of blood? What were the defects of the old operations, but that the surgeon knew not how to procure this adhesion? that he had no means by which he could stop the bleeding? The hæmorrhage was fatal to most of those who needed to suffer this operation; and the few who survived lingered through all the miseries of a nine-months cure, tedious and imperfect, with conical, ulcerated, and tender stumps. What indeed is the chief perfection of modern surgery, or the excellency of our operations? but that in bleeding from great vessels we trust nothing to compression, cauteries, or astringents, but tie our arteries firmly; and that we talk no longer about mundifying, incarning, or cicatrizing of wounds; that we never dress the cut surfaces as distinct wounds, but put the sides or lips in close contact, and keep them so. We boast nothing of our own powers, but trust all to nature; whose business it is, to make those surfaces adhere which will adhere; or reunite by the slower process of suppuration and granulation, those parts among which there has been a loss of substance." (J. Bell on Wounds.)

We have thus taken the liberty of copying the masterly and impressive language of this author, in order to convey a lively and firm conviction in the mind of the student, of the established, and in its application to practice, most important fact, that cut surfaces, if placed "neatly and evenly in contact with each other," will adhere: that from the slightest to the most serious wound, the process of healing is not in the smallest degree accelerated, but, on the contrary, greatly retarded by balsams, astringent gums, ointments, and other idle inventions for "mundifying, incarning, or cicatrizing of wounds." We repeat then this most important practical rule, than in endeavouring to heal recent wounds, the whole duty of a surgeon consists in securing bleeding vessels, and then bringing the edges of such wounds as accurately as possible in contact. "The rest we leave to nature."

When this union can be effected and retained (which it can in a great number of instances) without the aid of stitches, so much the better. This is likewise another improvement in modern surgery. In the most trivial wounds, the older surgeons were used to torture the patient with stitching, when the object, as it is now most satisfactorily proved, can be obtained with more readiness and safety by the mere application of a simple adhesive plaster. As this, however, is not always the case, we are to proceed in describing those circumstances in which the sewing of a wound is, and those in which it is not, necessary or proper.

When the skin merely is divided by a longitudinal cut, the edges of the wound are to be brought together by the adhesive plaster, by common court-plaster, or by a plaster of diachylon. "In applying such plaster, we are careful first to let the bleeding subside, then to make an assistant put the lips of the wound neatly together; then we apply one end of the sticking-plaster to the skin on one side of the wound, and let it fix there so that we may pull by it; then we pull that edge by the plaster; then moisten the remaining half of the plaster; then lay it neatly down over the opposite edge of the wound; then apply successive plasters till we have crossed the whole line of the wound; then, if any one of the slips of plaster has lost its hold by the oozing out of the blood, we take it gently off, wipe the surface, and apply a new one neatly, until we have got the whole clean and fair, all the plasters sticking soundly; and, lastly, we lay a compress over the whole, which we bind down a little with a circular roller, in order to prevent internal bleeding." This substitute for sutures is to be employed, likewise, in fleshy wounds which do not penetrate deep: it is to be used in parts where the skin lies close upon the bone, as in the back of the hand, and upon the hairy scalp. Even, however, in superficial wounds, when they are angular it will sometimes be necessary to employ one stitch of the needle in the situation of the angle, which will thus be supported while sticking-plasters, in the manner just directed, are to be applied to the sides of the wound, where the lips can be easily brought into contact.

When wounds, even although they may not be very deep, are made in parts which are constantly subjected to the action of strong muscles, as in the cheeks or lips, a stitch of the needle is to be employed; or that suture made use of which is termed the twisted or hare-lip suture, from its bein g principally had recourse to in order to unite the cut edges of a hare-lip. The manner of using this suture is the following: The broad edges of the wound are brought as nearly and neatly as possible in contact, and transfixed at opposite points with pins employed for the purpose. In the hare-lip operation, two of these pins are inserted, one at the edge of the lip, and one in or above the middle of the cut; we then twist a thread from one to the other pin, in the form of a figure of 8. (See fig. 9 in the Surgical Plates.)

In long and deep wounds among muscular substance, stitching will generally be requisite, and in proportion to their length must the stitches be multiplied. We are commonly directed by authors to make "for each inch of the wound, one stitch of the needle," passing, according to the extent of the wound, so many separate ligatures, which, after being all passed, are to be each tied over the surface, first by a single, then by a slip-knot. In this manner is the interrupted suture of the antients formed; which they distinguished from the continued suture, from the latter being sewed in the manner of a continued seam all along the wound. In each interstice of the interrupted suture, it will be necessary to lay one strip of adhesive plaster.

When the wound is still deeper, so that the stitches cannot go to the bottom, the compress, and what is called the uniting bandage, must be applied after stitching. This is formed by putting a double-headed roller round the part, passing one head through a slip in the opposite side, and drawing both at once.

"If the wound is pretty deep among the muscular flesh, so that the several stitches of the interrupted suture would make (if tied by the common knots) an awkward and painful suture, likely to excite inflammation, we then convert the interrupted suture into what is called the quilled suture; which is made by splitting each end of the ligature (after the stitches are made) into two threads; then laying a quill or bougie along each side of the wound, we tie all the ligatures of one side round one bougie; then draw that bougie tight down, by pulling the ligatures from the other side; then tie the ligatures also on the other side, round the opposite bougie; so that the two bougies, like two large rolls, keep the sides of the wound neat and even." This suture is not often employed.

After describing these different methods of effecting union between the divided edges of a wound, it is necessary to caution the reader further against using them indiscriminately in very deep muscular wounds. "Stitches after all can support only the edges of the wound, while it is the compress and the uniting bandage that must support all below." Thus stitches carried to a great depth have not only failed of their object, but have too often been the immediate occasion of convulsions, inflammations, and their long and dreadful train of consequences.

Stitches must also be employed cautiously if the patient, previous to the accident, has not been in firm health; or where he is to be exposed during the cure to the contaminated and deadly atmosphere of a crowded, filthy, and unventilated hospital.

With respect to the manner of arresting the bleeding, when one principal, or several ramifications of an artery are divided in a wound, so that profuse hæmorrhage takes place, the application of the tourniquet (fig. 10) is called for. The arteries are afterwards to be taken up, and secured in, the following manner: The tourniquet being a little loosened in order to discover the artery, an assistant makes a noose on the ligature to be employed: this being placed over the tenaculum (see fig. 11), the sharp point of this instrument is pushed through the sides of the bleeding vessel; and so much of it taken out from the surrounding flesh, as is sufficient to afford surface for a secure knot, which the assistant makes upon it.

If, from the depth of the wound, the tenaculum cannot be used, the crooked needle is to be employed instead; and if it is to be passed under the artery, as little of the muscular substance as possible is to be included in the ligature. If the artery to be secured is superficial, and lies against bone, as in the temple, in the hand, or the foot, it will be best secured by a firm compress. If it is convenient to make this compress within the wound, it may be formed of a piece of sponge, cork, folded leather, or linen. Such application will necessarily for a time interrupt the cure by adhesion.

When the wound has been sewed, the ends of the ligatures that are round the arteries are to be left hanging from its corners.

Such then is the immediate business of the surgeon, viz. to arrest hæmorrhage; and to bring as speedily as possible the divided edges of the wound into contact, in order to ensure the commencement of that adhesive process already spoken of. But with the closing of the wound the surgeon's business is not finished. For the most part, indeed, if the junction has been duly effected, if the patient is in health and properly managed, a certain degree of union will be shortly formed, the ligatures that have been employed will come away on the fourth or fifth day, and the adhesive action that is going on will not amount either to actual inflammation (although it is called the adhesive inflammation), or be accompanied by any systematic irritation of consequence. In the progress, however, of cure, in all wounds that have been closed by ligature, some degree of actual inflammation is always produced; and for this reason, that the ligatures themselves cannot but act as local irritants. Now if the tendency in the system is to inflame; if the stitches have been carried too deep, or the ligatures are too lightly pulled; if there is blood poured out under the skin, by which it is separated from the parts below; if, in a word, any cause has place of either separation or undue irritation; instead of the kindly progress of this adhesive natural and healthy action, pain, inflammation, and swelling of the parts, will ensue; and if these arise to any extent, "you must immediately undo your bandage, draw out your pins, or cut your stitches, and take away every thing that is like stricture upon the wound: these prudent measures may abate the rising inflammation, and prevent the total separation of the skin; while you may still endeavour to keep the wound tolerably close by the more gentle means of sticking-plasters.

"But should the inflammation rise still higher, and should you perceive that a total separation and turning out of the wound are inevitable; you must throw all loose, put a large soft poultice round the whole, and forsake without hesitation all hopes of procuring adhesion; for should you in this critical juncture persist in keeping the parts together by sutures, the inflammation would, in the form of erysipelas, extend itself over the whole limb, attended with a fetid and bloody suppuration, wasting the skin with great loss of substance. Therefore throw all loose, apply your poultice, allow the wound to separate right as it is, and to pass slowly into a soft and easy state of suppuration; and then a second time try to bring the edges up to one another, not by stitches, but by adhesive straps, or by a gentle bandage.

"When the wound has fallen into a full suppuration, then the suppuration, granulation, and all that follows, belong (as indeed adhesion also does) to nature alone, over which we have no other power than that of supporting the action of parts, *i. e.* keeping the system in good health; and when the suppuration goes wrong, it is in general by taking the form of a profuse, thin, gleety discharge; and this profuse discharge is to be suppressed, and the right suppuration restored, by bark, wine, rich diet, and good air; and this is what is usually meant by supporting the suppuration, or moderating the profuse discharge." J. Bell's Discourses on Wounds.

Of contused, and lacerated, and gun-shot wounds.

From the above observations, it will readily be inferred that (unless in cases of systematic irritation, or unfavourable circumstances), if a wound does not unite and heal, it is because its divided edges are not placed and preserved in neat and even contact; and this inference will serve to explain why those wounds are of most difficult and intractable treatment, which are not simple and fair divisions of parts with cutting instruments, but are what authors term contused and lacerated. A contused wound, in systematic language, is that in which, without the skin being penetrated, the parts below are crushed or broken, rather than divided; if the outer skin is broken at the same time, the wound is said to be contused and lacerated; such are gun-shot wounds. Suppose an individual to receive a ball from a musket or pistol, in the arm or thigh; suppose that the ball has entered at one point and passed out at the opposite, has taken a more oblique direction, or, instead of passing out, has lodged among the muscles of the part; in either case we shall have not a mere division of substance, in which the divided vessels can be secured, and the separated edges brought again into contact, but there will be a bruise rather than a clean cut; it will of course be impossible to dispose the parts so as that the adhesive action shall commence, and therefore "no gun-shot, nor indeed any bruised wound, heals by adhesion."

In this then consists all the peculiarity of gun-shot wounds: it is not that the ball (as the antients supposed) is possessed of any poisonous quality, that such wounds are difficult and tedious in healing; but solely because the injury inflicted is in the shape of a bruise, not of a cut; the vessels and fibres are crushed, not divided.

If then gun-shot or bruised wounds cannot be made to heal directly, or by adhesion, it follows that the treatment they demand is in some measure peculiar; we are, therefore, now to discuss the question of such peculiarity, and in so doing we shall for the present limit our remarks to those wounds which have not penetrated the thoracic, or abdominal cavities. The symptoms of wounds in the breast and belly, we have already enumerated; on their management, medical and surgical, we shall shortly enlarge.

Treatment of gun-shot wounds.

In gun-shot wounds which have neither penetrated the two great cavities of the chest and abdomen, nor have been made upon the head, the principal points of consideration are, the direction or place of lodgment of the ball, whether one or more bones have been splintered or broken, whether any considerable artery has been torn up, whether the wound has reached any of the joints, and lastly, whether the ball has carried with it any foreign matter, such as the patient's clothes. These points are to be determined by an acquaintance with the anatomy of the parts; by probing, scarifying, or dilating the wound; and by an attentive examination of the symptoms which the injury has occasioned.

"All probing should be done at the time of the wound," while the parts are still deadened by the injury, and before pain and inflammation have come on. The finger is the best probing-instrument; "it is not apt to catch upon tendons or nerves; it does not so much as the probe endanger the arteries; and by feeling with the finger, we judge most accurately of the condition of the wound. The finger both directs our operations, and instructs us what is to be done. Perhaps we feel the ball, and then we cut directly upon it; perhaps we feel the wound making a crooked or spiral turn, and we follow it with our incisions; perhaps we are sensible that it touches a great artery, and in working with our bistoury we are careful of that artery; we know also where the ball has touched a joint, or broken any bone; accidents which not only increase the danger, but which may even incline us in certain circumstances to cut off the limb. In short, all that we resolve, is from the information that we have through the finger, and it directs all our operations."

What are these operations? Either to scarify or dilate the wound, as circumstances shall demand, to make a counter-opening when necessary, and to extract balls, clothes, or splinters of bone. The purposes of scarifying are, "to open the vessels that they may bleed, to enlarge the wound that when it inflames it may have room to swell," and to enable the surgeon when requisite to take up the bleeding arteries, and to extract the ball, the splinters of bone, or any other foreign and irritating material.

Every gun-shot wound which is deep and penetrating, with a narrow opening, and with a tense fascia (even if no foreign body is to be extracted), requires immediate scarification; the incision, it must be carefully remembered, is "to pass through the fascia as well as the skin; the wound must have vent, as the older surgeons were wont to express themselves, in other words "it must have room to swell" during that inflammation which inevitably precedes its cure. The stricture, as in strangulated hernia, must be taken off. So far then all is plain and simple. But the practice is too often in the cure of gun-shot wounds more complicated. Counter-openings are sometimes to be made; splinters or foreign matters are to be searched for and taken out, and great vessels to be secured. When the ball has passed entirely through, the opening which it has formed by its exit is called the counter opening; when it has passed a considerable way, but not entirely through, it becomes the business of the surgeon to make this counter-opening in order to extract the ball. This practice is advised by the generality of surgeons, "when the ball has only passed two-thirds through the limb." Such direction is for the most part to be followed, and the operation should be performed as speedily as possible.

But there is also another kind of counter-opening (let this rule be especially attended to), which the surgeon is at times obliged to practise. The opening which he must afterwards make in the middle of a long wound, when the track of the wound swells, or when the abscess forms, and the matter, the sloughs, and the foul ichor, seem to be confirmed. For example: a man is wounded by a ball, which breaks one or two of the fingers, pierces the hand, runs up the fore arm, rakes along the bones, and goes out far from its entrance, as at the elbow or shoulder-joint. Here we can hardly prevent a long suppuration, and too often an exfoliation or spoiling of the bones: and three openings are required; one where the ball entered, another at the counter-opening or that by which the ball passed out, and if the swelling, pain, irritation, or perhaps nervous symptoms, come on, then there will be required also another opening in the middle of the wound. Such an opening will ease the swelling, and prevent a suffocation of the wound. It will prevent gangrene, bring on a good suppuration, and allow a free vent for the matter; it will also prevent sinuses, and so save the arm; and it will save us from the severe or rather cruel practice of the older surgeons, who were accustomed, in such cases, to run a large seton through the tube of the longest wound. These last (setons) are only proper when the wound has become entirely callous, and pours out a thin gleety discharge; or when, from the adherence of some piece of cloth which prevents its healing, healthy action cannot otherwise be excited.

So far then with respect to the scarifications which are required in gun-shot wounds; we now proceed to treat of the extraction of balls, cloth, or splinters of bones.

Here dilatations rather than scarifications are needful: for there is this difference between scarifying and dilating; that scarifying is that superficial incision of the mouth of the wound by which we relieve the tension of the fascia or the stricture of the skin; but dilating is that deeper incision which we make by pushing our finger deep, and to the bottom of the wound, following it with the bistoury, to make a free way for getting at the bleeding artery, or extracting the fractured bone. When we wish then to extract the ball, we are to employ free incisions, The fingers are to be used more than the forceps; these when the ball is found are to be introduced, and made to grasp it. Sometimes the ball will have been stopped by a bone and flattened, without breaking or splintering such bone; at other times, however, the bone by the force with which the ball has struck it will be shivered: in this case the splinters of bone are to be all carefully taken out, and the limb treated as in other cases of fracture. If the ball has entered and sticks in the bone, so that it cannot be extracted in the common way, then a more free incision must be made, and the trepan applied; "or if it is a narrow and firm bone, M. de la Faye orders us to cut the bone both above and below, so as to cut away that piece in which the ball is fixed."

But it is principally on account of fractured bones, wounded arteries, or pieces of cloth, that these dilatations of a wound are called for. "It is only the openness of the wound, and the nearness of the ball, that tempts us to search for it; for a ball sometimes works its way outward through the cellular substance, and comes to the surface with little pain, or often it lies without danger buried in the flesh for years, or for life. If there was no other occasion for opening the wound, we shold never give the patient pain on account of the ball, since it seldom itself gives him pain." It must, however, be carefully kept in mind, that wounds, even though fair and promising for a short time, will never heal kindly while the foreign matters above-mentioned are suffered to remain.

When there is much blood spouting from a gun-shot wound, it will be concluded that a great artery is injured: in this case the surgeon, guided by his knowledge of the anatomy of the limb, will make free dilatations from the mouth of the wound, until he finds the vessel, which he will tie up or secure. He must not, however, if the bleeding artery is of a large size, trust to compress or bandage. A piece of lint dry, or with some simple ointment, is then to be laid over the orifice of the wound, its sides are to be brought as close together as possible, without occasioning much irritation, and adhesive plaster or bandage to be placed over the whole. But there is another kind of hæmorrhage from gun-shot wounds still more dangerous, which may be called the secondary hæmorrhage. This often occurs eight or nine days after the injury was first received, and the patient has often fallen a victim to it, even when "at the first the wound was scarcely stained with blood." This hæmorrhage is occasioned by the loosening of the eschar of the mortified and bruised parts, leaving a breach in the sides of a great artery. In the course then of healing a wound, the proximity of which to a considerably artery is known, the patient ought to be attentively and incessantly watched: and in some cases it is necessary to keep constantly a tourniquet round the limb.

We conclude this part of our subject by repeating the motives for scarifying and for dilating gun-shot wounds. The first is, for the purpose "of opening the vessels that they may bleed," and in order thus to reduce the wound as nearly as may be to one made by a cutting instrument. The dilatation of a wound is for the purpose of enabling us to secure any great artery that may have been divided, and to extract splinters of bone, or any other foreign material, the ball itself being that about which, on account of its shape and smooth surface, we are the least solicitous.

Of tubular or penetrating wounds.

But there is further another kind of wound which is different in its nature and treatment from that made by a plain and fair division of parts, viz. a penetrating or tubular wound, such as is made by the bayonet or sword; and in this last case it is the surgeon's duty to bring it as much as possible into that condition in which its sides may, by being applied to each other, adhere. "Suppose," says Mr. J. Bell, "a young man in fighting a duel with the sword, is wounded in the sword arm, his antagonist's weapon goes in at the wrist, and out at the elbow. If in such case any great artery is wounded, then indeed it injects the arm with blood, forming a proper aneurism, so that we are forced to cut up the fore arm, and tie the wounded artery; but if it is merely a flesh wound, it is no doubt somewhat dangerous from being deep and penetrating; but still it is so little different from a common and open wound, that could we bring the sides of this tube-like wound fairly in contact with each other, it would close in a day; and the reason that it does not happen so is plainly this, that the blood which exudes from the very small arteries is sufficient to fill the tube of the wound: it not only fills it, but the bleeding going on withinside, while it is prevented by a compress and close bandage from getting out, the tube of the wound is not only filled but dilated with blood, and therefore cannot adhere, just for the same reason as the healing of an ill-amputated stump is delayed where the arteries, not being fairly tied, have bled after the dressing so as to fill the bason of the stump, and separate the flaps from each other. This not only prevents adhesion and brings on suppuration, but produces a gangrenous stump filled with foul and stinking matter, partly purulent, and partly filled with blood."

The obvious inference from all this is, that the healing of those kinds of wounds of which we are now speaking, is principally to be facilitated, nay, is alone to be effected, by cleansing it of this blood (when no important artery is divided), by closing the mouth of the wound with a slight compress, and "laying its sides together with a slight bandage." It was in thus cleansing these wounds of blood previously to closing them, that the remarkable success attended what was denominated some time since in France, the secret dressing. This used to be performed by men who were denominated suckers, one of whom was present at every sword-duel. "The rencounter ended the instant that one of the combatants received a wound; the sucker immediately applied himself to suck the wound, and continued sucking and discharging the blood till the wound ceased to bleed; and then, the wound being clean, he applied a piece of chewed paper on the mouth of the wound, tied up the limb with a tight bandage, and then the patient walked home."

This mode of treatment has proved successful even in wounds which have pierced, or passed through, one of the cavities, when there have been no veins, nor any great blood-vessel, wounded.

In a deep and penetrating wound, therefore, the method of cure consists in purging it of its extravasated blood, and causing its sides to adhere. We do not here need to make incisions or scarifications, as in gun-shot wounds, unless for the purpose of securing some great artery that may have been divided.

Having thus gone over the surgical treatment of wounds, fair, angular, bruised, lacerated, and penetrating, we now proceed to lay down some rules respecting the medical management of patients under these injuries, and which is still more important than the surgery itself of wounds; "for if the connection is not understood betwixt the particular wound and the general health; if the army or hospital surgeon (and the same remark applies with modifications to private practice) does not know with a glance the constitution of a patient, or the true state of his sore; if he is not careful to retain some general principle, which, like a mystic clue, may lead him through this labyrinth, he will see thousands dying around him without knowing the cause, like the fable of the Grecian camp falling under the invisible shafts of Apollo."

Among the very many mistakes and unmeaning prejudices which have crept into the practice of both medicine and surgery, that of indiscriminate blood-letting has, perhaps, proved the most pernicious. Than this practice followed up, as it has been, nothing can possibly be more preposterous, or more dangerous. The writer of this article not many days since heard of an instance (an extreme case it must be confessed, yet, as such, more especially illustrative of the injudicious conduct now referred to) of a superannuated lady, by some accident having been literally scorched to death: the surgeon who was summoned found himself preceded by another "practitioner," who was actually, while the writer's friend entered the room, unsheathing his lancet in order "to take some blood." In like manner, with more colour of propriety, it must be admitted, when a wounded patient is first brought to a surgeon, it is by numbers, even to this day, deemed a necessary preliminary to further proceedings, to bleed the patient. "The sovereign cordial of the landlady" is often more appropriate; and many lives have, perhaps, been saved by the absence of the village surgeon.

Let the following invaluable rules be treasured in the mind of the young practitioner, not as dogmas to force, but as principles to regulate, his practice. They are more directly drawn up for the use of army and navy surgeons, but will be found highly important to surgeons in general.

1st. "When your wounded patient is first brought to you, he is in great confusion; there is a tremor, a tonic stiffness, or almost a convulsion of the whole frame; there are coldness, fainting, and nervous affection; but it is merely a nervous affection, and it must be treated as such. You may expect it to subside in time, and therefore should give some good warm cordial, and large opiates to quiet the commotion. This is no time for bleeding, whatever the nature of the wound may be. If the stupor continues, you should give cordial draughts and wine.

2d. " If this nervous commotion being quieted, a sharp fever should come on, still do not bleed, but rather be upon the reserve; for perhaps this, which at first seems to be a pure inflammatory fever, may turn out to be a fit of an ague, to which the patient is subject; it may be a low and malignant fever; it may be an attack of some camp disease; and if a diarrhœa, great weakness, and low muttering delirium, should come on immediately after you have bled your patient freely, you would be distressed at the thought of what you had done, and you would indeed have much to answer for.

3d. " Reserve your bleedings for those more dangerous cases, where high inflammation is so often fatal, and do not bleed in wounds of the hips, shoulders, or limbs. Reserve bleeding for wounds of the breast or belly, or great joints; for in all wounds of cavities, inflammation, which can hardly be escaped, is the great danger.

4th. " If a man is wounded after a full meal, there can be no doubt that a gentle vomiting must be useful, where it is allowed by the circumstances of the wound. The old physicians found their advantage in it, and ascribed the good effects of vomiting to the preventing of crude and ill-concocted chyle from entering into the system, so as to kindle up a fever. There is no doubt that a meal which was no load during health, will be a great oppression upon a disordered system, and the carrying it off must be a great relief, although the old physicians, by talking this useless jargon about ill-concocted chyle, might almost provoke us to reject both the doctrine and the practice. The system cannot be weakened by a gentle emetic; and if the system should fall low after vomiting, it were easy to substitute a fitter support, and better excitement, than that of an oppressed stomach and loaded intestines, by first discharging these crude meats, and giving, when the stomach was emptied, food of easy digestion, and cordials suited to the condition of the system.

5th. " But in every wound there comes a period of weakness, in which we repent of every bleeding we have made, even when it was really needed; a period in which, by confinement and pain, occasional fever, diarrhœa, profuse suppuration, or colliquative sweats, the patient falls so low that it is not easy to support him through the cure: and thus there are two great principles in the treatment of gun-shot wounds: that even at first we should be sparing of blood; and that the period of weakness which is to succeed, is the great danger; on this single point hangs all the practice."

The author afterwards adds, that in mere flesh-wounds we are not entitled to bleed; for if there is no wound of a joint, or fractured bone, the first inflammation never runs too hight.

By due attention to the above rules, the surgeon will never find himself at a loss with regard to the immediate requisitions of the wounded, either in army, navy, hospital, or private practice. It will scarcely be necessary to observe, that where immediate bleeding is judged necessary (and this is always the case, as above stated, in wounds of cavities and joints), it may be employed most freely in the young, full-fed, vigorous, and plethoric, in dry and healthy situations, in the spring of the year, when no epidemic disorder prevails, and when the patient is afterwards to enjoy all the advantages of cleanliness, air, and a suitable diet.

In the progress of the cure, the surgeon is still not for a moment to lose sight of the intimate connection between the condition of the general system, and the state of the wound. Still fever is to be distinguished from inflammation: and the two opposite kinds of inflammation treated of in the article Medicine, vol. ii. p. 250, are likewise to be sedulously discriminated: the one will require a low diet, evacuating medicines, and, as it is expressed, a cooling antiphlogistic regimen; the other as loudly calls for bark, wine, opium, elixir of vitriol, and above all pure air, and (so as not to overload or oppress the weakened organs of digestion), rich or rather nourishing food. Here, instead of further reducing the system, " you must trust to air and cleanliness, and bark and wine."

We now proceed to speak of the treatment of wounds in the two cavities of the chest and belly.

The first and great danger in a wound which has penetrated the thoracic cavity, is that of suffocation from blood poured into the air-cells, or towards the trachea. The first and principal object then of the surgeon is to obviate this consequence as speedily as possible; and here immediate and oftentimes frequently-repeated bleedings are called for, even should the patient be in a condition unfavourable to the discharge of blood. " Here it is your duty to keep the patient low, and to drain his system so thoroughly of blood, that none shall pass towards the lungs to suffocate him, and that there may not be blood enough in the system to serve as fuel for that inflammation which sooner or later must come on."

When the blood is merely poured into the cellular membrane or cavity of the breast, without entering the air-cells, the finger, as already mentioned, is to be introduced into the wound; or if this wound is too high for the necessary discharge of the extravasated blood, a fresh wound may be made lower down upon the breast, and this so that the surgeon may have it in his power to reach and tie the intercostal artery, if this artery has been divided.

For the emphysenia or windy swelling, which is often so alarming to the bystanders, but which is in reality the most trivial symptom, scarifications are to be made in order to discharge the collected air.

If, during the cure of a breast-wound, there comes on a pricking in the side; if the cough is aggravated, the discharge becomes more copious, and the systematic irritation increased, there will be reason to suspect the remains of some irritating material, as a splinter of bone; in this case, the wound is to be probed, injected, and every endeavour made to extract the irritating cause.

" Sensible, at every turn, how slight a matter will irritate the pleura and lungs, the surgeon will never allow himself to do so unnatural and cruel a thing as to pass a great cord across the chest, which is thus easily irritated by the most trifling piece of bone or rag of cloth; but he merely lays a bit of oiled caddis gently within the wound, with a large emollient poultice over all."

To conclude. In the wounds we are now describing, the surgeon must in the first day bleed copiously, and repeatedly; he must again bleed should bloody expectoration recur, weakening the system in order to prevent suffocation; " and when the time comes in which the oppression is forgotten, and the danger of suffocation, and the bleedings from the lungs, are over, he begins to support his patient's strength with opium and bark, and nourishing diet and milk."

Wounds in the abdomen. While the danger from wounded lungs is chiefly of suffocation, in wounds of the abdomen, as before stated, we have principally to fear either sudden death from internal hemorrhage, or peritonæal inflammation, when the bleeding has not been so profuse. Against this internal bleeding, bleeding from the arm is the great preservative; and this, as in wounded lungs, must be done with a very liberal hand. When the peritonæal inflammation has come on, the patient must be assiduously preserved from all motion and irritation; clysters of a mild gentle kind must be injected, the belly fomented, and opiates adminstered.

No food is to be given for the first ten or twelve days; nourishment is to be conveyed by clyster, or if any thing is taken by the stomach, it must be extremely mild and gelatinous. If the wound has not penetrated the intestine, but part of the sound gut is protruded, it must be gently returned with the finger, and the outward wound stitched over it.

When, from the passing out of the fæces, it is evident that an intestine is wounded, this is not to be searched for with the finger, but suffered to remain; and from the universal pressure among the parts, the outward and inward wound will be brought opposite to each other. If, however, the wounded intestine is protruded, it is to be connected by a single stitch to the external wound, in order that the fæces may be thrown out from this last, and the adhesive process encouraged.

When, through a narrow wound, a sound bowel is obtruded, and becomes inflamed, the stricture is to be relieved by opening the wound a little wider, the intestine is to be carefully returned, and then the outer wound stitched.

Before we quit this subject of wounds, an apology may be thought necessary for enlarging disproportionately on this division of the article. We have done so for the purpose of illustrating the advantage that practical surgery has received from the natural, as opposed to the artificial cure of wounds; a fact which the young surgeon will find it necessary to impress on his mind as a directory in every step of his practice, whether operative or medicinal. We shall conclude this section by an extract from an author to whose incomparable treatise on wounds we have been principally indebted for what information the preceding observations may have coveyed.

" It is an old, but it is a becoming and modest thought, that in our profession we are but as the ministers of nature; and, indeed, the surgeon, still more than the physician, achieves nothing by his own immediate power, but does all his services by observing and managing the properties of the living body; where the living principle is so strong and active in every part, that, by that energy alone it regenerates any lost substance, or re-unites, in a more immediate way, the more simple wounds." J. Bell's Discourses on the Nature and Cure of Wounds.

Of aneurisms.

Wounded arteries cannot always be secured. Very often, as we have above stated, a large vessel is divided or punctured at a considerable distance from the surface of the wound, or in situations where the artery cannot be commanded: the blood is by consequence immediately and profusely poured out, spreads among the contiguous parts, and produces an aneurismal tumour. This is the false or diffused aneurism of authors, and the manner in which it is formed is sufficiently obvious.

The progress of this aneurism varies according to the situation and size of the artery that has been wounded. In the course of a few hours, the blood has been known to diffuse itself through the whole extent of a limb; at other times a very small tumour about the size of a horse-bean will remain of the same size for some weeks. As the increase of the tumour in false aneurism is generally occasioned by a diffusion of blood among the surrounding parts; it does not, like the true aneurism immediately to be noticed, become more prominent as it enlarges. In the first stages of the disease, a pulsation is almost always perceived in the tumour. This gradually lessens, and often at length becomes imperceptible. After some time, more or less according to the depth and magnitude of the wounded vessel, the skin becomes of a livid appearance, the member becomes stiff, painful, and the contiguous joint immoveable, the integuments at length give way, and if the artery is large a fatal hæmorrhage ensues.

When an artery has been accidentally punctured by the transfixing of a vein, an accident which has happened sometimes in blood-letting at the arm, the extravasated blood either diffuses itself into the surrounding cellular substance, or, when the vein and artery are more immediately in contact, the communication between the vessels is preserved; the vein, by the consequent impetus of blood comes to be dilated, and what has been denominated varicose aneurism occasioned.

This kind of tumour may be recognized by the tremulous kind of motion which attends it, accompanied by a peculiar hissing noise, and by the tumor entirely disappearing for a time upon pressure.

When from accident or disease the coats of an artery lose in any particular point their ordinary power of resistance to the blood's impetus, and the diameter of the artery becomes in consequence dilated, the true or encysted aneurism is formed. It was, indeed, to this dilatation of arteries, without the rupture of their coats, and extravasation of blood, that the term aneurism was originally and is more properly applied.

In this disease, although it may be situated near the surface, the outer skin at first is of a natural appearance, the tumour is compressible, and a pulsation may almost always be observed in it. As the swelling increases, the skin becomes paler than ordinary, parts of the tumour are often firmer than others, and the pulsation cannot be discovered at all points upon pressure. Pain now comes on, the skin becomes discoloured as in false aneurism, an oozing of bloody matter is perceived, and at length the tumour bursts, and if the seat of the disease has been a large artery, in one of the cavities of the body where compression cannot be applied, death is the inevitable consequence. Sometimes the fatal termination is occasioned by the gradual destruction of surrounding parts. Even bones have become carious in consequence of their proximity to a large aneurism.

Besides these three species of aneurismal tumours, the false, the varicose, and the encysted, Mr. J. Bell describes another disease, which he calls aneurism from anastomosis. This, our author observes, is constituted not by the dilatation of any one branch of an artery, but by a mutual enlargement of the smaller arteries and veins; it proceeds from a trivial size to a large and formidable tumour; it is characterised by perpetual throbbing, which at length becomes a continual and distinct pulsation. It beats strongly when the circulation is unusually accelerated; in spring and summer, its pulsatory motions become fuller and more acute; it goes on to form sacs among the cellular substance, or among the dilated veins. These become at length livid, and burst from time to time; and then, as in other aneurisms, the tumour pours out its blood, and, according to its extent, reduces the patient.

Diagnostic marks. The existence of an aneurismal tumour is not always to be pronounced with decision, for although pulsation might be regarded as a true diagnostic character of the disease, it is not absolutely so; for other tumours may be situated so near a large artery, as to be regularly affected by its pulsations. When there is any doubt of the nature of the swelling, pressure should be made on it; and if it disappears or lessens, and immediately recovers its size upon the pressure being taken off, it may be considered as an aneurism. In the advanced stages, however, even of an aneurism, the reduction cannot always be effected.

Causes. The simple statement of the mode in which the two first species of aneurism above noticed are occasioned, is a sufficient account of the causes producing them. The true or encysted aneurism appears for the most part to depend upon a diseased disposition; often, indeed, it is brought on by violence or accident, but even then the pre-disposition is generally to be suspected. Women are less obnoxious to aneurism than men, especially the large aneurism of the ham; and this Mr. J. Bell ascribes to their exemption from the hard labour of the other sex. To this conclusion, however, it has been objected, that even where the labour of females is greater than that of the men, and where even their occupations are such as to occasion those exertions which principally endanger the artery, the immunity is still the same.

When aneurism is produced gradually and without violence, this disordered pre-disposition is more evident. In this case, likewise, the prospect of cure from operation will be more faintly marked than when the tumour has succeeded to external injury; for this reason a diffused and varicose aneurism promises to be remedied by operation, with more surety than the true or encysted aneurism.

Aneurisms, likewise, are more or less dangerous according to their situation. When they are formed in large blood-vessels near the heart, they are not the subject of operation; and it had generally been conceived that even in the extremities, when they were seated high up, as in the axilla, or ham, this would be inadmissible on account of the complete stoppage to the circulation, which was imagined a necessary consequence of obliterating the great artery of the thigh or arm. By an anatomical and practical investigation of this subject, it has, however, been demonstrated that the inosculating vessels are in either instance sufficient to supply the limb; and that where failure attends the operation for aneurism, it is to be ascribed to other sources. In this substitution of the collateral branches for the arterial trunk, consists, indeed, the cure of aneurism, when it is effected without operation.

Treatment. The cure of every species of aneurism has been attempted by continual pressure on the tumours. In the false, or diffused aneurism, however, no advantage can be derived from this treatment. In the varicose aneurism, moderate and equal pressure may be attended with benefit; and even the true aneurism, when the artery is so situated that pressure can be made, has been cured according to the accounts of authors by this means. When attempts of this kind do not seem to promise any benefit, the operation ought to be speedily performed.

When first the operation for aneurism was practised, it was invariably the rule to secure if possible the large artery leading to the tumour by the tourniquet; then to cut into the sac, lay the cavity of the tumour freely and fairly open, clear it of the clotted blood, secure the artery by ligature, and treat the wound according to circumstances. In some cases it is necessary still to pursue this plan, as in a large and spreading aneurism of the groin; but where the artery leading to the tumour can be dissected and taken up before it reaches the cavity of the sac, it has been proved that this mode of operating is the most expedient. Mr. John Hunter first proposed it, by directing, in popliteal aneurism, that the great vessel from which it is nourished should be laid bare on the fore part of the thigh, that the artery should be obliterated by ligature at this part, and that the tumour, now deprived of its nourishment, should be left to be dissipated by the absorbents. This plan is now generally adopted. The surgeon dissects down upon the artery, in the part which is judged most convenient for the operation, ties the vessel at two places at half an inch or more distant from each other, cuts it across in the middle between the ligatures, and thus destroys its communication with the tumour; the blood is gradually solicited by the inosculating branches, which enlarge and come at length fully to supply the place of the trunk.

In performing this operation, the surgeon is to dissect the artery very clean; it should be carefully tied by itself, without including the accompanying nerve; a firm waxed ligature, without any intervening substance, is to be passed round it by means of a blunt needle, or crooked probe, and the wound treated in the common manner.

In the aneurism by anastomosis, Mr. Bell observes that the only radical cure is complete extirpation: we are not to cut into it, or to attempt the interruption of any particular vessels leading into it, but the whole group of vessels by which the tumour is supplied must be entirely extirpated.

Of fractures.

Fractures are not in all instances easy of detection. Pain, swelling, distortion, loss of power in the injured member, shortening of the limb, and a peculiar crepitating sound upon the part being handled, are described as the signs denoting a broken bone; these, however, are all, excepting the last, which cannot in every case be perceived, in a greater or inferior degree, common to bruises, sprains, dislocations, and injuries independant of fracture.

When a bone is simply divided, without any protrusion of its broken ends, lacerations of considerable blood-vessels, or any other circumstance to render the accident complicated, the practice of the surgeon is obvious and easy. In wounds of soft parts, we have seen, adhesion is insured by merely bringing their divided edges together; in like manner, though much more tardily, junction will be effected between the divided extremities of a fractured bone, by replacing and preserving them in even and steady contact. The healing of wounds is not accelerated, but on the contrary retarded, by the several contrivances and interferences of the older surgeons: so by the cruel practice of tight compressing, bandaging, and the use of machinery, in fracture, not only unnecessary pain is occasioned to the patient, but the process of cure, instead of being facilitated and hastened, is considerably impeded. Nature, in either case, will not be interfered with.

The time which bones take in uniting is proportioned to the age and health of the individual. In persons of middle age and firm constitution, a simple fracture of the arm will for the most part be fully and firmly united in a little more than a month from the accident. Fractures of the shoulder and thigh-bone are, under the same circumstances, about six weeks or two months in healing; while the smaller bones, as the clavicle, the ribs, the fibula, and the bones of the hand, seldom occupy in their cure more than three weeks.

In simple fractures, provided the parts have not been unduly irritated, either by much motion after the accident, or by tight straining bandages, the symptoms of inflammation will subside in a few days. Sometimes, especially when the surgeon has been called late, it is necessary to subdue the local irritation by solution of lead, the application of leeches, and other means used in common inflammation, and these it is often necessary to continue for several days. Now and then it will be found expedient to bleed from the arm. These requisitions must be determined by the good sense and judgment of the surgeon. It is impossible to lay down abstract rules for conduct. To bleed, however, merely because a bone is broken, is a practice equally unmeaning and erroneous with that before alluded to, with regard to wounds in soft parts.

Before speaking of individual fractures, we shall present the reader with the following instructions of Mr. J. Bell, which, although especially applied to a broken leg, will be found applicable with proper exceptions to fractures in general.

"In setting a broken limb," says our author, "there is no extension required but such as common sense would direct you to use were you not a surgeon. Lay the patient in bed, and lay the limb upon a pillow; or if you design to use splints, have two long troughs, or pieces of pasteboard, (in figure 66 is represented the usual splint employed in a fractured leg) bent into a hollow form, lined, or rather cushioned, with two or three piles of flannel, with tapes or ribands, four or five in number, attached to the outside of one of the splints, by which both splints may, after all is over, be gently tied together with bow-knots, to be slackened or tightened according to the swelling of the limb. The pasteboard ought to be soaked and softened a little, that it may take a shape suitable to that of the limb.

A long splint of this kind being laid flat upon the bed by the side of the fractured leg, desire one of your assistants to apply his hands broad round the upper part of the limb, and grasp it gently and steadily; take the foot and ancle in the same manner in your own hand, slip your left hand under the broken part of the limb, and then sliding it gently along, lay it upon the pillow or its splints. The pillow should be like a mattrass, flat and firm.

Begin then to lay the limb smooth; let your assistant again grasp it, by spreading his hands upon the thigh or below the knee, with the design of extending along with you, not by lifting the leg from the pillow, but rather by keeping it down, and steadying it by pressure, while you with both hands lift the foot and ancle; grasp them gently, but very firmly; raise them a very little from the pillow, and draw them gently and very smoothly. When you have thus extended and smoothed the broken leg, in a manner which you almost suppose agreeable rather than painful to the patient, press it down steadily and gently; keep it flat and pressed until it gets a seat and bed in the pillow. If splints are applied, the limb is to be pressed against the lower splints; the upper splint is then to be laid above it, and by grasping the soft and moistened splints, you must model them a little. When the whole has taken a form, take several tapes one after another; and after having tied them in a general way, go over them again one by one, and tie them a little closer, so as to keep the limb agreeably firm."

This author, in another place, remarks (when speaking of fracture in general), "when the limb by accident has been disordered or shortened, you are to venture, without fear of hurting the callus, to extend it anew, and lay it straight."

It may be proper to observe, that while much inflammation is present, we are to defer the application of splints, even in the gentle manner above advised, till such inflammation has in a considerable degree subsided.

Of fractures of the lower extremities. Fractures of the body of the thigh bone may generally be ascertained by the signs above enumerated. When, however, the injury is in the neck of the bone, it requires much attention to distinguish luxation from fracture (see the section on *Luxation.*). Here we may observe, that luxation is usually occasioned by straining or twisting of the limb; while perpendicular falls, or leaps, are the more common causes of fracture. When the crepitation is discovered, the nature of the accident will be unequivocal.

Fracture of the thigh, on account of the strong contraction of the large muscles of this part, is the most difficult of cure. To counteract this tendency to contraction, the joints of the thigh and knee are to be gently bended; one assistant is then to take hold with both hands of the upper part of the thigh; another is to support, and very moderately to extend the lower extremity, while the surgeon adjusts the fractured bones. After thus reducing the fracture, the limb is to be secured, by being laid in a well framed case, stiff, and adapted to the form of the limb, bending gently, in order to admit of a relaxed posture, lined with a woollen cloth, or with flannel, each hollow being filled up with little cushions of tow; another splint is then to be laid on the opposite side of the thigh, the whole braced gently down with ribands, and then both the thigh and its case bound to the pillow by tapes. In order to preserve it against the weight of the bed-clothes, a frame with hoops may be placed over the thigh. From time to time the limb is to be examined, in order to ascertain whether the bones retain their situation: if it is disordered or shortened, the limb may be again gently extended and properly adjusted. After the second week, a small degree of flexion and extension may be used daily, in order to prevent an anchylosed joint.

Machines have been invented, one particularly by Mr. Gooch, represented in fig. 64, in order to obviate the contractile tendency, by making a counter-extension. These machines, however, do by no means answer the intention proposed. The counter-extension should not be continual, but must be made occasionally, and with the hands. When the patella is fractured, it is generally in the transverse direction. In healing such a fracture, the leg should be extended, the patient should be laid on a mattrass, and a splint placed under the limb, of sufficient length to reach from the upper part of the thigh to the under part of the leg, to which the limb is to be attached by straps. The fractured bones are then to be brought together, and the inflammation subdued by local applications. Here the pressure of the bed-clothes should likewise be guarded against by a frame of hoops, or some other contrivance. When the bone has been divided longitudinally, the common adhesive plaster is usually sufficient to maintain the junction. In transverse fractures, the divided pieces of bone recede from each other: and unless it can be done with facility, they are not to be brought together, for much force employed in this case would occasion a stiffness of the knee-joints and lameness. The bandage sometimes employed in a transverse fracture of the patella is represented in fig. 65.

For the treatment of fractures of the leg,

5

see the directions given above. When the bones of the tarsus, metatarsus, and toes, are fractured, it will be necessary to apply a splint to the fractured part, and in general a large one beside over the sole of the foot.

Fractures of the upper extremities. Fractures of the scapula are by no means common: they are ascertained by the touch, by the great pain of the part, and by an incapability of moving the arm. It is with difficulty that the parts are retained after replacement: a long roller is to be used, with which the shoulder is to be supported, and the arm is to be kept suspended, in order to relax the muscles.

A fracture of the humerus is generally easy of detection. When it has been reduced, two splints are to be employed, and a flannel or linen roller is to be applied gently over them. The arm is to be supported in a sling. In a few days, or a week, from the accident, it may be examined, to ascertain whether the broken ends have been properly adjusted.

In fractures of the fore-arm, whether one or both bones are broken, the joint of the elbow is to be gently bent. Two splints of pasteboard are to be used, one large and long, upon which the arm is to be laid, the other smaller, is to be placed over it, and they are to be secured by slight tapes, ribands, rollers, or the twelve-tailed bandage. (See fig. 63.) The arm, during the cure, is to be supported in a sling, with the palm of the hand towards the breast.

When the olecranon is fractured, the arm must be preserved in an extended state, by a long splint reaching from some way above the elbow-joint, down to the point of the fingers. The arm should be hung by, and connected to, the side. In little more than a week from the accident, the dressings are to be removed, and a slight motion given to the joints, in order to prevent anchyloses.

When the carpal bones are fractured, there is usually considerable inflammation, which must, as much as possible, be obviated by local applications: splints are to be employed as in fractures of the fore-arm, and the arm is to be supported in a sling.

In fractures of the metacarpus, a firm splint should be placed over the palm of the hand, which should be made to reach from the points of the fingers to the elbow. When a finger is broken, a splint of pasteboard, moistened and moulded into the form, is to be used; and a large roller may be applied all over the hand, in order to prevent the motion of the fractured finger.

Of fractures of the clavicle, ribs, sternum, and spine. A fractured clavicle may sometimes be perceived by feeling along the course of the bone. The motions of the shoulder-joint are likewise necessarily impeded. In reducing this fracture, the arm is to be raised, so as to bring the ends of the bones towards each other; and it is to be preserved in this position till union is accomplished.

When a rib is fractured, which may generally be ascertained by feeling with the fingers, if one portion rises over another it should be reduced by moderate pressure, and a bandage applied round the chest, which should be continued for some weeks. If a portion of the rib is forced inwards, some surgeons direct that an opening be made over the depressed part, which is to be elevated by the finger or forceps. When the sternum is fractured, a similar treatment is said to be required. In this last case it is necessary sometimes to trepan.

When the vertebræ are broken, the accident is for the most part fatal, and by the fractured pieces pressing upon the spinal marrow, a palsy is occasioned in the parts below the injury. The surgeon, however, is to attempt the replacement of the bones, and when part is depressed, an incision has been advised, in order to raise the depressed portion.

Of compound fractures.

Those fractures are called compound in which the external teguments are wounded, from the same accident by which the bone has been broken. These are necessarily of much more difficult management than cases of simple fracture. Some surgeons indeed have indiscriminately recommended amputation of the limb in every case of compound fracture; while others have questioned the propriety of amputating, even for the worst accidents of this kind. This question, like many others, has been agitated too much in the abstract. The propriety of immediate amputation, or a prior attempt to preserve a limb, will depend not merely on the extent of the injury, but on the age, habits, and constitution of the patient, as well as the circumstances which he shall be under during the cure. In the army or navy practice, amputation is often necessary, where in private it would be premature and cruel.

When we are to attempt the cure of a compound fracture, the first object is to remove such pieces of bone as are detached in the form of splinters, as well as other extraneous bodies. If there is merely a protrusion of the bone through the wound, without any separated pieces, we are to attempt an immediate reduction, as in simple fracture. If this cannot be effected even by pretty strong extension, an endeavour must be made to force in the bone by pressure. If, on account of the narrowness of the wound, it is impossible to reduce the fracture, the wound must be dilated by a straight probe-pointed bistoury. It is sometimes necessary to saw off part of the projecting bone, in order to effect the reduction. When this has been accomplished, the wound is to be closed as much as possible, a pledget of emollient ointment placed over it, and the limb secured by an eighteen-tailed bandage. In order to encourage adhesion, and prevent suppuration of the wound as much as may be, the limb without inordinate pressure should be supported as firmly as possible. When suppuration has come on, the limb is to be carefully dressed every morning. Indeed the chief business of the surgeon will be to preserve the wound clean and clear by regular washing and sponging, by laying clean lint upon it, and by the occasional use of spirituous application. It is scarcely necessary to add, that the patient's health must be supported with much care. While causes of irritation are avoided, a due excitement must be kept up. (See the section on wounds.)

Of luxations.

Dislocations, like fractures, are sometimes difficult immediately to discover. An incapability of moving the limb, pain, tension, a lengthening, shortening, or other deformity, and often considerable inflammation, are the general symptoms attending a dislocated or luxated bone.

Endeavours to reduce luxations ought to be made as speedily as possible: as they grow older, they grow more difficult of treatment. Indeed, after a bone has been a considerable time dislodged from its place, it often forms a new and artificial joint for itself among the contiguous muscles, and the subject of the accident is by consequence rendered irrecoverably lame. When, however, dislocation accompanies fracture, it is sometimes necessary to cure the latter before the reduction of the former is attempted. This is the case when the fracture is contiguous to the joint.

When much local inflammation accompanies luxation, it is to be carefully subdued by the common anti-inflammatory applications; and, according to circumstances, it will be sometimes requisite to bleed at the arm. When the luxation has been reduced, the parts must be retained in their situation, by placing the limb in a relaxed position, and by applying appropriate bandages.

Luxation of the superior extremities.

Of the os humeri. The shoulder-joint may be luxated by the head of the humerus falling downwards and backwards. The more usual kind of dislocation, however, is by the head being forced downwards and forwards. An upward luxation cannot happen without a fracture of the upper parts of the scapula. The signs of a dislocacted shoulder are inability to raise the arm, the head of the humerus being felt out of its proper place, while a vacuity is observed under the acromion.

This luxation is often extremely easy of reduction. The surgeon should be provided with assistants to extend the arm, by means, if necessary, of a belt, or any substitute for this placed round the arms, with long straps attached to it, by which to extend the limb: another assistant is to draw back the shoulder-blade, while the operator, standing on the outside of the arm, directs the extension according to the situation of the bone, and thus raises it into the socket. Sometimes, when assistants are not at hand, an arm-dislocation may be reduced by placing it on the knee, and thus acting as with a lever. The arm, especially if the patient has been subject to the accident, may be supported in a sling some time after the reduction.

Luxation at the elbow is not common; it is attended with a shortening of the fore arm, a projection behind above the elbow; while in the bend of the elbow the extremity of the humerus may be felt.

It is to be reduced by gradually extending the fore-arm rather in an oblique direction, and gently increasing the curvature of the elbow, and by endeavours to disengage the ends of the bones. After the reduction, the muscles should be relaxed by preserving the elbow for some time rather in a bent position.

When the fore-arm is dislocated at the wrist, the rotatory motion of the hand is prevented. After the bones are replaced, a tight flannel roller should be bound round the wrist, and the arm supported in a sling.

When the bones of the wrist are luxated, which is by no means a common accident, much pain and inflammation follows, and the motion of the joint is destroyed. The arm is to be supported, and but very gently extended, and the bones pushed into their proper position, which is to be preserved by bandages or splints. The metacarpal bones when dislocated are to be managed in a similar manner. When the thumb or fingers are dislocated, the phalanx is to be held by an assistant, while the surgeon elevates the dislocated end, and replaces it.

Luxations of the inferior extremities.

Dislocations of the thigh-bone are not very common. This bone is however susceptible of displacement in four different directions; upwards and obliquely backwards, downwards and a little forward, directly forward upon the pubes, and backwards over the ischiatic notch.

In the first the limb is shortened, and the knee turned inwards. When the neck of the thigh-bone is fractured (an accident which has been confounded with dislocation), the knee and foot are on the contrary directed outwards: the limb also in case of dislocation is moved with more difficulty than when the neck of the bone is fractured.

This dislocation is to be reduced by extension downwards and forwards. The patient is to be laid on his side, and a double sheet may be placed under his thigh, which being attached to some fixed points, will serve to raise and support the limb during the proper extension.

In a dislocation downwards and forwards, the signs are reversed; the head of the thigh-bone may here be distinctly felt in the perinæum. The extension in this case must have an upward and outward direction; its reduction is easier than in the preceding case. In returning the ball of the bone into the socket, the surgeon must be careful to act cautiously; too precipitate a reduction is apt to push it again out of its place, and produce an upward dislocation.

When the dislocation is forward upon the pubes, we are directed by some surgeons to lay the patient on his side, and support the thigh by means of a pulley fixed to some point above the limb: the operator thus assisted is to press the knee inwards. In the fourth kind of hip-dislocation (over the ischiatic notch) the length of the limb is not interfered with; but the accident may be ascertained by the disappearance of the trocanters. Here the reduction must be attempted, by giving the bone an upward direction, while the knee is pressed inwards. The limb should not be used for some days after the reduction.

The patalla can only be dislocated upwards and downwards by a rupture of its ligament or tendons; in this case the bone will be drawn up, and assume the appearance of fracture. It may however be luxated to one or the other side. For reduction, the limb must be extended; and in lateral luxations the edge of the bone at the greatest distance from the joint may be depressed, by which the opposite edge is elevated, and may be returned into its place.

The tibia is very seldom luxated at the knee-joint; when the accident happens, it is easily detected. In reducing such a dislocation, the limb should be gently extended, and the bones replaced by the hand. Inflammation ought, with much solicitude, to be guarded against.

Dislocations of the ancle-joint are very rare. Indeed they are scarcely possible without a fracture of the end of the fibula. In reduction an extension of the foot, even with the leg, should be made, till the bones are readjusted. Luxations of the tarsal bones are to be treated in a similar manner. When the metatarsal bones and toes are dislocated, the reduction is to be effected as in the metacarpus and fingers.

Luxations of the spine, coccyx, ribs, and clavicle.

In consequence of the firm ligamentous connection of the vertebral bones, dislocation seldom happens without fracture. When it does, it is almost invariably fatal. When the coccyx is displaced, it may be generally felt protruding. It is to be reduced by pressure with the fingers. This bone is sometimes forced inwards, and occasions much pain, tenesmus, and sometimes a suppression of urine. In this case the finger is to be introduced into the anus, and the pressure made outwards. Dislocations of the ribs are exceedingly uncommon. All that can be effected towards the reduction is to bend the body backwards, in order to press out the rib.

When the clavicle is dislocated the end projects forwards under the skin, near its common place of junction with the breast-bone. The reduction is to be made by pushing the protuded bone in with the fingers, while an assistant pulls back the arms and shoulders. The arm must afterwards be properly supported in a sling.

Luxations of the bones of the head and face.

When the cranial bones are separated, the head must be supported by a bandage. If one of the nasal bones is luxated inwards, it is to be elevated and reduced by inserting a tube into the nostril covered with lint. If the luxation is outward, the bone is to be pressed in by the fingers, and a double headed roller applied round the face. To reduce luxations of the lower jaw, which are not very unfrequent, the thumbs protected by a covering of leather, are to be thrust as far as possible between the jaws, and then the fingers being applied on the outside of the angle of the jaw, attempts should be made to bring it forward till it moves a little. It is then to be pressed forcibly down.

Of amputation.

Than this, as it is now performed, scarcely any operation in surgery is more simple and secure. To preserve the teguments, so as that they can be fairly brought over the stump, and properly to tie, or otherwise secure the bleeding vessels, constitute the points of practice in amputation; and, as we have previously shewn, rank among the most important improvements in modern surgical practice.

The following are the general directions for performing amputation: The tourniquet is first to be placed on the most convenient part of the limb for securing the larger arteries; a circular incision is then to be made with the amputating knife (fig. 71) or common scalpel, which is to pass all round the limb, and go through the skin and cellular substance; these are next to be dissected away from the muscles to such a distance as will allow the divided edges of the integuments to come into contact over the stump. The skin thus separated is to be drawn up from the muscles, or turned back upon them, and kept by an assistant in this situation, while the operator now makes another incision at the edge of the reflected skin, beginning from beneath, and cutting in a circular direction down to the bone. The muscles are then to be separated from the bone, as the skin before was from the muscles, to such a distance, as to enable them afterwards completely to cover the end of the bone. The whole mass of flesh is then to be kept up from the bone by retractors (fig. 72 and 73); the periosteum is to be divided all round in the place where the saw is to be applied, but not at all taken up from the bone: the saw (fig. 74) is now to be used, and the bone divided with long firm strokes, taking especial care that during this part of the operation the assistant holds the limb with steadiness. If there have been any splinters of bone left, they should be immediately taken away with pincers (fig. 75). The retractors are now to be removed; the principal arteries drawn up, and tied free from the nerves. Some warm wine, or other cordial, is to be given to the patient. The wound is to be cleared of blood, the muscles and skin are to be fairly laid together over the stump; adhesive plaster and the requisite bandaging applied, the patient taken to bed, and the wound treated in the common manner (see section on wounds). Unless any untoward circumstance arises, a complete cure will be thus made in the course of a few weeks.

After this general statement of the mode in which amputation is to be performed, we might now be expected, as in our accounts of fracture and luxation, to go over the separate parts which at different times come to be operated upon. Such minuteness, however, would be inconsistent with our plan and limits, and we shall merely observe, that in all cases of amputation the above rules apply; that the surgeon must be determined by his own judgment respecting the particular point at which a limb should be amputated; it will of course be regulated by contingencies, but as a leading rule it may be observed, what indeed is almost too obvious to require notice, that in general as much as possible of the limb should be preserved.

When joints, are to be operated upon in the way of amputation, further directions are necessary. Amputation at the larger joints ought indeed, in every instance, if possible, to be avoided; for a wound in a joint is, as we have already seen, invariably hazardous. When, however, in consequence of abscesses in these parts, compound fractures at the union of bones, caries, or other diseases, it becomes necessary to amputate at the joints, it will be necessary, after first securing the artery, to make a circular incision, as in common cases of amputation; then on each side of the limb another cut is to be made in a longitudinal direction, from the joint to the circular incision, and passing down to the bone; the ligaments of the joint are now to be divided, and the limb removed. If during the operation any branches of arteries have been divided, these are to be taken up or secured, the wound is to be cleared of blood, and the muscles and skin brought neatly and fairly together. The union is to be effected by adhesive plaster and by proper bandages.

Wounds or injuries of the head.

Among many erroneous and unfounded opinions, this is by no means the most uncommon; that wounds of the head are dangerous in proportion to the degree and extent in which the skull is fractured. "It is the injury of the brain alone which is dangerous," and "very often are so close, the connection and sympathy of all the external and internal parts, that the brain is hurt by the very slightest injury of the scalp or bone," while the skull may be extensively injured, and the accident be comparatively trivial. Affections of the brain from blows or wounds of the head, are immediate or secondary; the last are those which do not directly follow the injury from which they proceed, but "make their slow insidious progress in the form of a disease." They are insidious, because they frequently arise to an alarming extent in consequence of a hurt which was at first deemed slight, and scarcely deserving of notice. They are slow: for a man, after receiving such an injury, shall perhaps continue in seemingly perfect health for more than a month, and shall at length fall a victim to the disorder, which has all this time lain as it were in embryo.

"One soldier, for example, shall have his temple grazed with a ball, shall hardly know that he is hurt, or be sensible for some time that he is indisposed; shall walk about for six weeks apparently in perfect health, and then all at once shall droop and fall low, become sick and weak; shall at last fall into coma, or awaken in the most dreadful struggling delirium, and then expire: and it shall be found, that the pericranium is separated from the skull, the skull itself black, and the dura mater inflamed and oppressed with pus. While, on the other hand, another soldier in the same battle shall be so wounded with a sabre, that the scalp, scull and all, shall be cut clean away with a wound even of the brain itself, and yet the patient escape; or which is more singular, a soldier wounded with a musket-ball, which is left sticking in the skull, with much depression, and many fractures of the bone, shall come to the hospital walking alone, shall suffer the extraction of the ball, and all the incisions and pickings of the bone which such a case requires; and shall eat and drink heartily, sleep soundly, and suffer not one bad symptom during the cure."

Most commonly, however, even in these secondary affections of the brain, a certain degree of sickness, faintness, and stupor, immediately follows the stroke, the blow, or the fall, upon the head. From this state the man revives very slowly; at length seems to have regained his health, but after the lapse of some weeks perhaps, the faintness, sickness, and giddiness, recur; then come on fever, delirium, weight or pain in the head, and every sign denoting a low inflammation of the brain; this state at length comes to be succeeded by paralysis, insensibility, and death.

This disorder "is plainly a diseased dura mater, and an abscess of the brain," almost sufficiently evidenced by the progress of the symptoms, but rendered doubtless when on the surface of the skull arises "a small, soft, puffy, regularly circumscribed tumour," not of the erysipelatous kind, for that denotes a mere affection of the scalp, nor a soft and fluctuating tumour, for this may proceed from blood poured out from one of the cranial arteries.

"The trepan is in this case almost a hopeless operation, and yet it is to be tried." The intention of operating under these circumstances is, to discharge that matter which collected either between the dura mater and skull, or between this membrane and the actual substance of the brain, gives rise to all the distressing and alarming symptoms. When this last is the case, it will be found necessary, not merely to trepan the skull, but to pierce the membrane. Such an operation will usually for a time lessen the patient's sufferings; "but often he is again oppressed, and sinks and dies; or if he lives, great fungi sooner or later shoot up through the opening, and by these, as well as by blood or matter, he is at last oppressed, and dies commonly in convulsions."

The danger in this last case seems to depend upon the exposure of the brain by the operation; the surgeon then will be careful not to multiply openings for the discharge of matter, "for the danger on one hand, viz. by oppression and inflammation of the brain, is just proportioned to the delay in opening the head: and on the other hand the danger after the operation is just proportioned to the number of holes."

The immediate injuries of the brain, as opposed to the secondary affections above described, are divided by surgical writers into those of compression and concussion.

A man, for example, receives a violent blow upon his skull, which by its force shall press in part of the bony defence of the brain directly upon the substance of this organ: he immediately falls down in a state of stupefaction; his pulse and breathing are oppressed, and he is carried off insensible. Now all this injury may arise from a fracture of the skull, when the fractured bone is pushed in upon the brain; or it may succeed to a similar degree of depression of any part of the cranium, even although not the smallest degree of fracture shall have been occasioned; indeed the fracture is not seldom a favourable circumstance. In either case the affections which follow result from compression.

Concussion is a kind of injury more obscure in its theory, but not less fatal in its consequences. It is an internal derangement of the brain, or of the nervous system, which dissection cannot trace, and which appears to be a shock to the whole, rather than an injury to any particular part of the organization.

In the former case, that of compression, relief may be expected from operation, but there is neither motive nor use in operating for concussion. In some instances of the former, blood-letting is imperiously called for; in the latter, to bleed is inevitably to increase the disease.

It is therefore absolutely necessary to decide early respecting the precise nature of the injury. This decision, however, is not in every case easy even to the surgeon who may have had frequent opportunities of comparative observation. Most of the symptoms which attend compression likewise accompany concussions; and the existence of depressed bone, which must form, at least in part, a case of compression, is not always to be detected by external examination.

In cases of an equivocal or undecided nature, where it is imagined that compression may exist, although it is not perceptible, it has been advised by a modern surgeon to trepan in many different parts of the skull, in order to ascertain and remove the cause producing the symptoms. "It often happens," says Mr. Benjamin Bell, "that no external mark is to be met with to lead to the seat of the injury; even after the whole head is shaved, and examined with the most minute attention, the skin will in various instances be found perfectly sound, without any appearance either of tumour or discolouration. A patient in such circumstances we suppose to be in great hazard, from the brain being compressed in one part or another; unless this compression is removed by an operation, he must, in all probability, die. In what manner then is a practitioner to conduct himself? The situation is distressing; but still, in my opinion, there should be no hesitation as to the line of conduct a surgeon ought to pursue, which should be quite the reverse of what is almost universally adopted." This author, in another place, adds, "it will be proper to perform the first perforation in the most inferior part of the cranium, in which it can with any propriety be made; and to proceed to perforate every accessible part of the skull, till the cause of the compression is discovered." Benj. Bell's System of Surgery.

In cautioning against such practice as is here recommended, we appeal to the unprejudiced judgment of the reader, under the sanction of high authority. It is observed by the celebrated Pott, "that symptoms of oppression are no good reason for cutting the integuments." And Mr. J. Bell, in his comment upon the above observations, thus addresses his readers: "I must in a few words entreat you to consider whither this practice would lead you. A boy is struck by another with a stone, lies for many days bleeding at the nose, comatose, vomiting, and with every bad symptom; his surgeons are all the while advising the operation, his friends are pleading for a respite, when the boy begins gradually to recover, and in a few days is perfectly restored. Consider," our author goes on to say, "if in any given case, the patient lying oppressed, and having no mark of injury outwardly upon the head, you should advise the trepan; while a man who had studied more the common sense of surgery than the authorities of school-books, should prevent this unmeaning operation; and if in the mean time the patient should be entirely relieved, what would become of you? Or if you should be allowed to perform the operation, and were to find nothing wrong, what consolation would that be?"

Indeed while there is but one motive for applying the trepan, viz. to relieve the brain from compression, whether that is from blood, matter, or depressed bone, the principal care of the surgeon ought to be, not to perforate the cranium upon the mere suspicion "of something lying somewhere," but on the contrary, to be ever wary of doing too much, rather than fearful of effecting too little, in the way of operation.

We cannot better conclude this subject, than by again extracting the rules of practice from an author, whom, from a sense of the rectitude and value of his doctrines and precepts, we have often taken so much pleasure in quoting. "If," says Mr. J. Bell, "there is an injury in the scalp, a hurt of the skull, an internal separation of the dura mater, or any injury which endangers inflammation of the brain; and if along with that kind of danger there are actually symptoms which mark inflammation of the brain; we try to prevent or moderate the inflammation by bleedings. If there is a concussion, and the patient lies oppressed, vomiting, with difficult breathing and a slow pulse, (and this, it may be observed, is the most frequent, direct, or immediate injury from a blow or fall on the head,) we give opium, wine, and all forms of stimulants. If there are along with this oppression external marks of injury after an accident, such as might cause extravasation of blood, or depression of the skull, in such case our duty is first to open the scalp, so as to examine the skull, and next to trepan the skull, if it is not sound, with the hopes of relieving the brain.' "If there is blood, it is to be known only by guess, by having opened the scalp at the place of the blow, in the expectation of finding a fracture of the skull, and by next trepanning the skull, in hopes of finding blood lying upon the surface of the brain. But still, if after opening the skull the patient should lie comatose and oppressed, it being plain he must die if not relieved; and if also from the tension of the dura mater we suspect there is blood under that membrane; we must venture to open it also, in hopes of relieving the brain. If matter lying upon the surface is the cause of compression, it will be known by the previous symptoms, by quickness of the pulse, head-ache, flushed face, turgid eyes, corded feeling in the head, and all the other signs marking an inflammation of the brain. And if after all these symptoms, shivering, languor, faintings, slight vomitings, and delirium, come on, we are sure of the case. If there is found a fissure of the skull, that fissure is not itself the cause of danger, but it is the mark of that degree of injury which may have produced extravasation: it also marks the place of the violence, and points out where we should apply the trepan. A fissure is not of itself a motive for trepanning the skull; but if with the fissure the patient lies oppressed, then the oppression is the mark of danger, perhaps from extravasated blood, and the fracture or fissure of the skull marks the point on which we should apply our trepan.

"When the bones are directly pressed down by the blow, our way of proceeding is very plain; if the bones are moveable, we raise them gently up; if they seem totally disengaged, we pick them away; if the bones are locked in with one another, and pressed under the sound skull, we cut one angle with the trepan, and that enables us to raise the depressed bone. In all this operation we should be gentle, and rather reserved; for when blood has covered the whole skull, from the sagittal suture, quite to the petrous bone, it has all been evacuated by one single opening, and the patient saved. When there has been pus generated in great quantity, and much of the dura mater detached, one single perforation has been sufficient. When pieces of skull have been apparently so detached from their membranes, that they have seemed irretrievably lost, they have notwithstanding lived and healed, especially in young patients; and often when the depression has seemed so great that the surgeon has neglected to raise it, or has been so difficult to raise that he has forsaken it, the patient has lived notwithstanding the great oppression, and been restored to perfect health."

Operation. The operation of trepanning will necessarily vary, according to the circumstances of the case; the following are given as the general rules of practice: After the head is shaved, an incision is first to be made through the integuments, in such a form as to enable the surgeon, when the operation is over, to bring the edges of the wound as nearly as possible together; when the part has been fixed upon for the application of the instrument, so much of the skull is to be denuded of its pericranium by a raspatory, (fig. 13) as will allow the trephine (fig. 14) to be fixed; a hole is to be made with the perforator, of sufficient depth to fix the central pin of the trephine, that the saw may be prevented from slipping; when the saw works steadily and securely, the central pin of the trephine may be removed; the saw is from time to time to be taken out of the groove, and cleaned by the brush (fig. 15.). During the progress of the operation, the depth of the groove ought to be examined; if one part is of greater depth than another, the pressure of the saw is to be made principally on the opposite side. The operator must often examine whether the piece is loose; when it is perceived so, it must be snapped away by the forceps (fig. 16.) or levator (fig. 17), for the sawing should by no means be continued until it is quite detached, lest the membranes of the brain are injured. When, after the piece of bone is extracted, the inner edges of the perforation appear ragged, they are to be carefully smoothed by the lenticular (fig. 18). The depressed portion of the bone is now to be raised with the levator: if there are any parts of bone totally disengaged, they are to be picked away, extravased blood let out; and, as above-mentioned, if blood or matter is contained under the dura mater, this membrane itself is to be punctured. From the extent of the fracture or depression, it is sometimes necessary to make more than one perforation: in these cases they ought to be made to run into each other, in order to prevent the necessity of dividing intermediate spaces. After the objects of the operation are accomplished, a pledget of lint, either dry or with some simple ointment, is to be laid on the wound in the dura mater (provided that membrane may have been punctured): the edges of the scalp are then to be brought up as nearly as may be together, and another piece of lint laid along the outer wound; some fine linen is to be placed over the whole, and the parts secured by proper bandaging, or by a common night-cap.

At every dressing the purulent matter is to be carefully absorbed by a sponge: the wound is to be treated upon the same principles as wounds in general; and should fungi arise out of its edges, we are, according to their nature and extent, to attempt their removal by caustic, by excision, or ligature.

Of inflammation, its characters and varieties.

Inflammation may be divided into ordinary, constitutional, and specific; the first dependant for its production upon those susceptibilities which in a greater or inferior degree are common to every individual, the second proceeding from a peculiar tendency to disorder in some constitutions, the last always arising from the application of a particular exciting cause.

For example. To that kind of vascular irritation which constitutes the inflamed state, and which has been the subject of inquiry in another place (see MEDICINE, Sect. *Phlegmasiæ*), all are obnoxious, provided the exciting cause acts with sufficient power: but those inflammations that are called scrophulous, although immediately excited by the same powers which are productive of common inflammatory action, will not in all individuals follow upon the application of such powers; such then furnish examples of constitutional inflammations. As an instance of the third or specific inflammation, we may adduce the venereal disease, either in its first introduction into the system, or in several of its secondary stages.

As all these disordered states have something in common, while at the same time each is distinguished by its separate characteristic, so the rules of treatment in relation to them are both general and particular. Thus the observations which apply to the management of a common abscess (the result of inflammation), apply likewise, to a certain extent, to one resulting from the venereal virus, while the requistions of this last are further regulated by the peculiarity of its exciting agent.

We shall first then treat of common, secondly of constitutional, thirdly of specific, inflammations. For the symptoms, progress, termination, and medical treatment of inflammation, consult MEDICINE. It is the simple surgery of this disorder alone that remains to be noticed. The local applications suited to the repulsion, or, as it is technically expressed, resolution of an inflamed surface, when the inflammation is of the active or sthenic kind, are the different preparations of lead dissolved in vinegar, mild expressed oils, or simple ointment. The first of these is often most conveniently employed in the shape of cataplasm, made by mixing the dissolved lead, Goulard's extract for example, with crumbs of bread. This application ought to be constantly renewed, and kept on the part cool. Lead is sometimes applied in combination with simple ointment; this, however, is not in general eligible, as the action of the lead is in some degree blunted by uniting it with oily or unctuous substances.

Local blood-letting by leeches, or by cupping and scarifying, is sometimes necessary, in order to reduce the inflamed state; and all heating, or otherwise irritating, applications to the diseased part, are to be assiduously guarded against.

In passive, asthenic, or indolent affections of the inflammatory kind, it is sometimes necessary, even while the inflammation continues in its first stage, to treat the complaint with local as well as general stimuli. In these cases we avoid cold applications, leeches, saturnine preparations, &c. and order warm and large poultices, made with linseed and oil, frequently renewed, fomentations, the infusion of white poppy, or of chamomile flowers, and sometimes even volatile embrocations.

When the suppurative stage of active inflammation has commenced, the repellent applications are likewise immediately to be laid aside. Action is now not to be checked, but encouraged; warm fomentations are to be applied; poultices made with bread and milk, with a small quantity of lard or simple ointment, are to be resorted to; these are to be laid upon the part soft and warm, and very frequently to be renewed. Sometimes when the suppurative process seems too tardy and indolent, it may be necessary to add to the poultices some of the heating or stimulating gums, such as galbanum, which may be made to unite with the poultice, by dissolving it in the white of an egg.

The completion of the suppurative process, or the full formation of abscess, is known by the cessation of throbbing, and other symptoms of suppuration, and by the pointing of the tumour, as well as its change of colour from a whitish or yellowish appearance. Sometimes when the tumour is not deep seated, the fluctuation of matter is evident.

The methods of opening abscess are by caustic, by incision, or by seton: the first, although still employed in some species of tumour, is at present by no means in common use; it is more painful and insecure than the mode by incision. When caustic is employed, a piece of sticking-plaster is to be laid on the tumour, with a hole cut into it, into which the caustic is to be introduced, and retained by plaster and bandage, until it has made an opening through the integuments of the tumour, which, generally, will not be till some hours after its application. When an eschar is formed, some emollient ointment is to be employed to soften and separate it.

When the knife is employed, all that is necessary to attend to is, to avoid any considerable blood vessels, to make the opening large enough to give free outlet to the matter, and at the most depending part of the swelling.

When a seton is used, such an instrument as represented in fig. 1, may be threaded with glovers' silk, inserted at the upper part of the tumour, and passed out at the under; and the matter of the abscess thus allowed gradually to discharge itself. Dry lint, changed once or twice a day, is the only dressing necessary in a common abscess.

When an inflamed part, instead of thus passing on into suppuration, becomes gangrenous, the external applications are required to be of a stimulating nature; such as solutions of sal-ammoniac, &c. in general, however, the arresting of gangrene is to be trusted to internal invigorating powers, and keeping the part clear and clean. When mortified parts lie deep, and are not thrown off by the living energy of the surrounding surface, it is often necessary to make incisions into the skin for the purpose of removing them.

Of ulcer. When the ischar or mortified part has been separated, the sore remains in the form of a simple purulent ulcer, which is one of the most common objects of surgical practice, the treatment of which is entirely resolvable into the means of assisting nature in her endeavours to procure proper and healthy granulations of new flesh, in preventing morbid luxuriancy, and disposing to an even and clear cicatrization. Various methods have been had recourse to, in order to accomplish these objects, such as turpentine, warm stimulating ointments, in conjunction with mercurial preparations; as an example of which, and as the best application of the kind, we may notice the common basilicon ointment of the shops, with the red-precipitate powder. But the management of obstinate ulcers has recently been abundantly facilitated by the employment of simple adhesive plaster, which is cut into strips, and laid carefully, firmly, and neatly, over the whole ulcerated surface; these, where it can be used, to be assisted by bandage. This practice was first generally introduced by Mr. Baynton, and has, with justice, been ranked among the highest improvements in modern surgery. At every dressing of an ulcer thus treated, the sore is first to be cleansed by sponge and warm water; if, notwithstanding the uniform pressure of the plasters, fungous excrescences arise, they may be touched, when dressed, with some kind of escharotic; the edges of the ulcerated surface are then to be brought up as near together as the loss of substance will admit of; and the strips of adhesive plaster separately passed over the sore, till it is entirely covered. Over this dressing common cerate spread on linen may be laid, and the bandages then applied. When the ulcer is attended with much inflammation and swelling, the management of it for a time is to be solely entrusted to warm and stimulative poultices. One of the most efficacious materials of which these may be constituted, and one of the best applications to obstinate ulcers of the leg, which are often attended with erysipalatous inflammation, is the grounds of stale beer.

Thus far of ordinary inflammation and its consequences: we now proceed to treat of this state as connected with, or modified by, a peculiarity of constitutional disposition. These kinds of inflammation are peculiar in their nature, and confined to certain parts of the system. Thus, inflammatory disorders of a scrophulous kind invariably affect secretory surfaces and cancerous inflammations, which are nearly allied to scrophulous, arise always in glandular parts. Suppose, for example, the breast of a female to be subjected to the causes of inflammation, the operation of such causes, if applied at a certain time of life, or under circumstances of cancerous predisposition, will end in the production of true cancer; the nature of the inflammation from the first being peculiar: while under circumstances of freedom from the cancerous tendency, an equal degree of actual inflammation may prevail in the breast, without having any peculiarity in its nature and progress, or without demanding a specific mode of treatment. Further, even in an individual predisposed to cancer, inflammation of a part which is not glandular, will, by consequence, not be cancerous. What, therefore, we have denominated constitutional inflammations, are inflammations of certain parts, and thus branch out into distinct diseases. We shall here only notice the two principal inflammations from a scrophulous diathesis, although every secretory surface is obnoxious to the affection; these are white-swelling of the knee joint, and lumbar, psoas abscess.

White-swelling. This disorder is most frequent in the knee joint, and indeed the name is usually made to denote a disease of this part.

Symptoms. Pain in the joint, especially on motion, or, when it is in a bent position, swelling, which gradually augments, with an enlargement and varicose appearance of the cuticular veins; while the joint swells, the parts below become either diminished or affected with an œdematous enlargement, partial suppurations, which break and form abscesses at different points; gradual decline of the patient's health, hectic fever. Sometimes the pain is more confined, and it is often then more acute; at other times the pain and swelling are from the first diffused through the whole extent of the joint.

Causes. White-swelling is a scrophulous inflammation. In those cases in which the enlargement of the joint commences with the pain, the pain itself being more diffused, the primary affection seems to be an inflamed state of the capsular ligament; in other cases the disease is perhaps originally seated in the bones. Mr. B. Bell has described these different species by the names of rheumatic and scrophulous; but the fact is, that they both depend upon the scrophulous diathesis; and it has been well observed by an able writer, "that between acute rheumatism and white-swelling, there is no sort of analogy, neither as to their causes, their symptoms, their terminations, their proper method of cure, nor any thing else." Dr. Herdman on White-Swelling.

Treatment. Both in the medical and surgical treatment of all scrophulous inflammations, it must be recollected that they partake more of the asthenic than the opposite character. Thus in white-swelling, however violent the inflammation, or urgent the pain, blood-letting, general or local, is seldom or never advisable. Blisters, warm fomentations, and bathing, volatile liniment, the counter irritation of caustic issues, mercurial friction, nourishing, but not irritating, diet, good air. When suppuration has taken place, "soft and easy dressings," warm poultices, small doses of calomel with opium. Cicuta? Amputation of the limb, which is often the only resource of the surgeon, yet it is not indiscriminately advisable, on account of the patient being, in some instances, too feeble and diseased to admit of the operation.

Of lumbar or psoas abscess.

Symptoms. Pain in the loins, which does not, as in lumbago, affect the muscles of the loins generally, but passes rather upwards in the direction of the spine, and downwards in an oblique direction, towards the inner part of the thigh. After the existence of this pain, for a longer or shorter period, marks of suppuration come on, and a tumour gradually appears in the groin. This is to be distinguished from hernia by a recollection of the preceding symptoms, and by the flaccidity and fluctuating feel of the swelling.

Causes and seat. This disease appears to be an inflammatory affection of the vertebral ligaments, occasioned by sudden alterations of temperature, blows, or any violence done to the part, and other causes of inflammation. It terminates in suppuration, which runs along the sheath of the psoas muscle, and thus appears in the groin.

Treatment. This, to be effectual, ought to commence with the commencement of the disease. When matter has formed to any extent, the malady is highly dangerous. Blisters to the loins, volatile embrocations; very small doses of calomel, with opium or hyoscyamus. When a tumour has formed in the thigh, which continues to increase, it is to be opened. During the subsequent discharge, the patient's strength is to be carefully supported, by nourishing diet, wine, opium, bark, and pure air.

Of cancer. Cancers, previously to their appearing in the form of ulcer, are termed occult. An occult cancer is a schirrous swelling of a gland, attended with lancinating pains, which state of parts often exists for some time before ulceration or open cancer is produced; this last, however, sometimes appears without any previous schirrosity. The symptoms of cancer will be best described by tracing the usual progress of a cancerous breast. A small knotty tumour is generally first perceived on some part of the mamma; this continues nearly in the same state, perhaps, for some months: it at length increases, and a pain is felt to proceed from it towards the axilla; the integuments gradually become discoloured, and at length ulceration is formed.

Causes and peculiarities. There has been much dispute whether cancer be a disease of parts merely, or of the system: all, however, that ought to be understood respecting the general nature of cancer, is, that a susceptibility, as we have above endeavoured to explain, exists in some habits, and especially at certain periods of life, to this malady, which in such habits may be induced by the same causes which occasion common inflammation. The usual time for the formation of cancerous mamma is when the menses disappear. Previous to this period, swellings of the breast assume more of the scrophulous character.

Treatment. Cicuta has been much extolled as a remedy for schirrus; faith in its virtues are, however, gradually declining. It may be combined with small doses of calomel. Mercurial ointment to the part, volatile embrocations, not too stimulating. Lac assafœtida has been employed as a lotion in occult cancer with seeming benefit. If the disease advance, no cure can be expected but from operation, which should be had recourse to early, previously to the extension of the disease into the contiguous glands.

Operation. If the skin be sound, a longitudinal or transverse incision, according to the shape of the tumour, is to be made with the scalpel along its whole length, at a small distance from the nipple; this incision is to pass through the skin and cellular substance, and while the patient's arm is extended, the mamma is to be carefully dissected from the integuments and pectoral muscle; all the glandular substance should be detached, although only a part be the seat of the disease. In closing the integuments after the completion of the operation, the twisted suture may be employed, assisted by straps of adhesive plaster; a pledget of simple ointment is to be laid over the part, covered by soft linen or tow, and the dressings are to be retained by appropriate bandage.

When the operation is performed, after the existence of the disease for some time in an open state, it will often be necessary to cut away a considerable portion of integument: the incision may, in this case, be made of an oval form; and if the axillary glands be found schirrous, the scalpel should be carried on full into the arm-pit, and the indurated bodies carefully dissected out. When the operation is over, the divided edges are to be brought up as nearly together as possible, and dressings and bandages applied, as in other similar wounds.

Venereal affection.

The venereal disease is an example of that species of inflammation which we have called specific. It appears in two forms. To the one is more generally applied the denomination of syphilis; the other is called gonorrhœa virulenta. These affections are imagined by some to originate from the same specific poison; by others, the cause productive of true syphilis, and that occasioning gonorrhœa, are supposed to be of a different kind. This last is perhaps the best founded opinion, viz. that the matter which, applied to the genital organs, produces a discharge from the urethra, called gonorrhœa, is not capable, under any circumstances, of producing true venereal chancre.

Symptoms of gonorrhœa. A peculiar itching and smarting sensation about the extremity of the urethra, attended with some feeling of stricture or tightness; this is succeeded by the appearance of mucus about the extremity of the penis, which soon increases in quantity: it is generally of a brown appearance, is attended with more or less smarting upon discharging the urine, and with nocturnal erections. Sometimes the lymphatic glands of one or both groins become inflamed, enlarged, and thus form bubo. The time at which the symptoms of gonorrhœa make their appearance is variable: sometimes the disorder will follow impure coition in the space of a few hours; at others it will be several days.

Treatment. In the first and inflammatory stages, demulcents largely drank, such as decoction of linseed, solution of gum arabic, tragacanth, &c. Mild purgatives, such as manna and senna. Opiates at night. Bathe the penis in warm milk and water. Saturnine lotions. If from the too precipitate or early use of astringent injections, or from other causes, the inflammation extends itself to the testicle, causing pain and swelling of this part (hernia humoralis), the scrotum is to be supported by bandage. Leeches are to be applied should the inflammation be violent, and the testicles are to be preserved constantly moistened with a solution of sugar of lead, or some other saturnine preparation. For the swelled glands, friction with mercurial or common ointment and camphor. Volatile embrocation. If the inflammation cannot be repelled, the suppurative process to be solicited by bread and milk poultices. If every symptom of the disorder go off, with the exception of a white mucous discharge from the urethra, which continues notwithstanding the use of astringent injections, give tincture of cantharides in gradually augmented doses, which will be for the most part found more efficacious than the balsams generally employed for this purpose. Should still the discharge continue, and, from the unusual appearance in the stream of urine, a stricture in some part or parts be suspected, introduce bougies.

Symptoms of syphilis. True syphilis is perhaps invariably introduced into the system through the medium of chancre, unless in cases where it is transmitted from parents to children. Chancre is a small ulcerated sore, occasioned always by contact or coition. This, when it appears on the penis, is frequently followed by an inflammation and enlargement of one or both groins; these, if neglected, pass on to suppuration; ulcers on the tonsils succeed, with eruptions of the skin, especially about the roots of the hair; at length come on pains in the bones, which are often highly excruciating, and although sometimes taken for, are to be distinguished from, rheumatic swellings, by their being rather in the centre of the bones, and deep seated, than in the joints, and superficial; by their not being accompanied with fever equivalent to the violence of the pain; by the absence of that general swelling of the soft parts which attends rheumatism, and sometimes by a circumscribed swelling extremely painful growing up from the bone. When any doubt exists respecting the nature of those ulcers in the tonsils, throat, &c. which are suspected to be venereal, they may generally be decided such by their peculiar coppery appearance: they are likewise, in general, more circumscribed than other ulcers, and their edges have a peculiar callosity.

Treatment. Mercurials given in such a form, and in such quantity, that what is called an alterative kind of action shall be for some length of time maintained in the system, without occasioning salivation, is an effect from mercury, which appears always to defeat its own object. Chancres on the penis may, if the application be made to them a very short time after their production, be totally destroyed by caustic, and the absorption of the virus and consequent disease thus prevented. When the swellings in the groin are first perceived, they are to be kept from enlarging by the vigorous application of mercurial ointment, which, if not inconvenient, is perhaps the best and surest mode of introducing this medicine into the general habit. For other preparations of mercury, see MATERIA MEDICA and PHARMACY. With respect to the time of continuing mercury, it may perhaps be laid down as a general rule, not to discontinue the medicine until two or three weeks after the apparent discontinuance of the disorder. Secondary affections, from the venereal action not having in the first instance been entirely subdued, are extremely frequent, and are always formidable. Opiates, sarsaparilla, and, recently, nitrous acid, have each been judged specifics for venereal affection; but it is now pretty generally supposed that they merely act as auxiliaries to mercurials.

There are some other affections that were not noticed in the article MEDICINE, which depend upon a specific poison, and which, though constituted by a species of cutaneous inflammation, are not, like the exanthemata of authors, preceded or accompanied by febrile irritation. The cutaneous eruptions which require to be noticed here, are the annulus repens, the tinea, and psora.

Annulus repens, ring-worm. This is a

prurient eruption formed in a circle; it affects children, and is thought to be constituted by small insects. These animalculæ Dr. Darwin supposes may be rather the effect than the cause of the eruption.

Treatment. Metallic or vegetable astringents in solution, such as nut-galls or white vitriol. The white precipitate ointment is perhaps equal, if not superior, in efficacy, both in this and the two following complaints; the head to be covered during the cure with an oil-skin cap.

Tinea, scald head. This eruption commonly breaks out about the roots of the hair; it appears in small ulcers, which at times spread over the whole head, and produce friable crusts.

The secretion of the contagious matter, upon which this disorder depends, is generally excited by poverty of diet, uncleanliness, and other mismanagement of infants.

Treatment. Shave the head; wash the surface first with warm water and soap; white precipitate ointment; tar ointment; a solution of corrosive sublimate; generous diet, cleanliness; small doses of calomel.

N. B. A milder disease than tinea often breaks out on the face and head of very young children: this (crusta lactea) is not infectious. It is to be treated by keeping the child clean, cool, and much in the air; and by sprinkling the eruption with calamine powder, if necessary, which is likewise the best application to those excoriations of the skin which are apt to break out about the genitals of infants.

Psora, itch. "Small pustules with watery heads, appearing first on the wrists and between the fingers." "There are two kinds of itch, that which appears between the fingers and the joints of the knees and elbows, and that which is seldom seen in these places, but all over the other parts of the body. The latter is seldom thought to be the itch, as it does not easily infect even a bedfellow, and resists the usual means of cure by brimstone." Darwin.

Treatment. Sulphur ointment; mercurial corrosive sublimate in a very weak solution; white precipitate ointment; sulphur taken internally.

Of indolent tumour.

Tumours which are not necessarily or in their origin attended by inflammation, are called indolent; these morbid enlargements of parts are principally seated in the cellular membrane: they are differently named, according to the nature of their contents. When the swelling is made up of a substance of the consistence of fat, it is denominated steatomatous; if of a firmer consistence, a sarcomatous tumour. When it is filled with a substance about the consistence of honey, the enlargement has been called a meliceratory tumour. The name artheromatous is applied to those swellings which are constituted by a substance of a harder kind. Sometimes the contents of tumours are formed of a coagulable fluid, when they are termed hydatids. Ganglions are swellings in the bursæ mueosæ of joints.

These tumours may be removed by making an opening with a lancet, if their contents be of a fluid nature, evacuating such fluid, and afterwards removing their sac. If the contents of the tumour are solid, they are to be extirpated by making a longitudinal incision through the integuments, and removing the tumour by the point of the finger, or any convenient instrument that is blunt.

Of nævi materni, corns, warts, and polypi.

When those marks on infants which are fancifully attributed to impressions made on the mind of the mother during pregnancy, do not rise above the level of the skin, they are not of course the subjects of surgical operation. Sometimes, however, these appear in the form of sarcomatous tumours, firm, prominent, and fleshy: in these cases the swelling may be cut out. If any considerable arteries run into it, these are to be taken up, and the skin that remains, brought over and united by adhesive plaister. If the tumour be connected with the sound parts by a narrow neck, it will generally be advisable to destroy it by making a ligature round its neck.

Corns are formed by a thickening and hardening of the external skin from pressure. They are to be treated by first bathing the feet in warm water, and then paring off as much of the swelling as can be done without giving pain. This operation is to be frequently repeated; some simple ointment may be laid over the corn, and all pressure avoided as much as possible.

Warts are to be removed by applying to them frequently any mild escharotics, such as a solution of blue vitriol, of crude sal ammoniac, &c. Sometimes astringent substances will make them subside, such as nutgalls: hence the common practice of applying ink to these excrescences.

Polypi are indolent tumours found in various parts of the body, as the nose, mouth, throat, vagina, uterus, and rectum. When, notwithstanding the use of astringent solutions, such as of alum, vinegar, &c. they continue to grow, become painful and troublesome, they are to be extirpated by the knife or scissars, when the roots of the tumour can be commanded, otherwise by tearing them up with forceps, fig. 3.; or, which is much less painful, while it is more secure, by ligature, of wire, of catgut, of silk, &c. The ligature is to be passed double over the tumour, and carried to its root by the fingers, split probes, fig. 4. or rings, fig. 5. The ends of the ligature are to be now introduced into a canula, fig. 6. which is to be pushed along the opposite side of the tumour, till its end reach the root of it, when the ligature is to be drawn with some tightness, and fastened to the canula, which is to remain in the passage; the ligature is to be daily tightened till the polypus drop off. When the polypus is in the throat, the ligature should be applied through one of the nostrils.

Diseases of the bones.

Bones, like the soft parts, are subject to inflammation, which often terminates in caries, or a kind of gangrene, forming the disease called spina ventosa, or gagræna ossis. This seems to be a scrophulous affection.

Symptoms of spina ventosa. Dull heavy pain following perhaps a blow on the part, or originating without any perceptible exciting cause; lameness and sensation of weight in the affected limb: after the continuance of these ymptoms for some time, without any appearance externally to indicate disease, the integuments, suddenly perhaps, will become pained and swelled. This arises from the matter having made its way through from the interior of the bone to the periosteum.

Treatment. After the abscess has been opened, let the parts be kept constantly clean and dry. In some cases it is necessary to apply the trephine, in order to remove the part of the bone that has become carious. Assiduously attend to the restoration and preservation of the constitutional excitement and health. Bark, steel, very small doses of calomel, good air, nourishing diet, chiefly of animal food.

The friabilitas and mollities ossium. The one disorder constituted by a disposition in the bones to be broken or injured from the most trifling exertion; the other, by a want of due firmness and hardness in the bone, are occasioned by disordered action in the secretory or absorbent vessels of these organs. They are alone to be remedied by internal strengthening remedies, suited to the nature of the prevailing malady.

The venereal node, as to its immediate cause, is obscure; the external swelling, with which after a time it is characterized, appears to be occasioned by an extension of the periosteum. Sometimes the pain of these tumours is mitigated by dividing the periosteum.

Among the diseases of the bones is often classed an affection which is very common, especially to young children, viz. a loss of power in the lower extremities, consequent upon a displacement of some part of the boney column of the spine. This, in fact, appears to be a disease of the ligaments. The frequency of this complaint in young children it is important to recollect, as the treatment, to be effectual, ought to commence early, and in its origin. Unless attended to with care, it is apt to be mistaken for a nervous or common infantile indisposition.

Symptoms. An unusual backwardness in walking, languor, listlessness, a tendency to hectic, and lastly, a feeling of protuberance or curvature in some of the spine.

Treatment. A seton in the back near to the disordered prominence, chalybeates, small doses of calomel, as in other scrophulous affections. Nourishing diet, cleanliness, air.

Of veresection and arteriotomy.

Blood-letting from the arm is an operation so simple and familiar as hardly to require notice. The ligature that is used for the purpose of stopping the venal circulation should consist of broad tape; this is to be firmly bound round the arm about an inch or two above the joint of the elbow; the intermediate space between this and the bend of the joint is in general the most convenient for introducing the lancet. The surgeon is to make choice of that vein which rolls least under the skin. The median basilic, although not always the most prominent, is usually chosen, both on account of its being less apt to slip from under the lancet, and because there is less danger of injuring any cutaneous nerves than when the cephalics are opened. The artery being felt to pulsate below is not to be regarded as an objection; for transfixing the vein under any circumstance should be carefully guarded against; and unless the instrument be thus carried through the opposite sides of the vessel, the artery, even if contiguous, must necessarily remain uninjured. In performing the operation, the thumb of the left hand is to be pressed firmly on the vein to be opened, a little below where the lancet is to enter; the instrument then being opened at about right angles, is to be laid hold of about half way down its blade; the surgeon is to rest his hand on the patient's arm, and to make the opening in the vein in somewhat of an oblique direction. When sufficient blood has been withdrawn, the ligature is immediately to be taken off, the arm cleaned with sponge and water, a dossil of lint, or piece of linen doubled, laid neatly over the orifice, and the tape bound over this in such a manner as to interfere as little as possible with the bend of the elbow.

When it is found impossible to bleed in this part of the arm, one of the veins may be pierced between the elbow and wrist. In this case the tape of course should be bound round below the joint.

When bleeding is required in the neck, the thumb is to be firmly pressed upon the external jugular about an inch below where the opening is to be made.

If venesection be required in the ancles or feet, a ligature is to be bound round a little above the ancle joint; the veins of the feet are usually prominent and superficial. The one that is most so is to be made choice of. Adhesive plaister is to be laid over the orifice when the operation is over.

Artiriotomy is only practised on the temporal artery. In opening this artery it is generally advisable first to divide the skin which covers it, before the lancet is introduced; the artery is then to be opened in the same manner as a vein: the discharge of blood may generally be stopped by cutting the artery directly across, and suffering it to retract. Bandages have likewise been contrived for stopping the flow of blood, one of which is represented in fig. 7.

Topical bleeding.

Leeches, scarifications of the skin with the point of a lancet, and cupping, are the means employed for topical bleeding. Cupping is performed by the scarificator and cupping glasses; the scarificator is an instrument so constructed, as, by means of a spring, several lancets are made to apply at one time to the vessels of the skin; over these punctures the cupping-glass is to be evenly placed, the air of which has been rarified by heat, as by burning a piece of paper dipped in spirits, and placing it in the bottom of the glass; the blood from the wounded vessels will immediately rise and flow into the glass. When it is required to take more blood than will fill one glass, the surface of the wound is to be bathed in warm water, wiped dry, and the second vessel immediately placed over it in the same manner as before.

It has been observed, that the flow of blood is facilitated in some instances by placing the cupping glasses over the surface to be scarified previously to the application of the scarifying instrument; and dry cupping is sometimes practised, in which, by the mere use of the glasses without the scarificator, a quantity of blood is diverted from other parts without being discharged.

Leeches are most easily applied by confining them under a wine glass; it is thought that these animals fix more readily if the surface be previously rubbed over with milk, or cream, or sugar.

Issues.

The most usual parts of opening an issue are on the fore part of the humerus, the hollow above the inside of the knee, the nape of the neck, the spine or between the ribs; in the two former places the pea or blister issue is commonly used, in the others the cord or seton.

A blister issue is made and kept up by the common blistering plaster being first applied, which is followed by the daily use of cantharides ointment. The pea issue is sometimes made by caustic, but more commonly, and much better, by pinching the skin up, and cutting it through, making a wound of sufficient size to receive the common issue pea; this is to be daily removed, a fresh pea put into the wound, and thus a purulent discharge will be excited and maintained.

The seton is, to be made with the seton needle, (fig. 8.) threaded with cotton or silk, this is to be pushed into the skin, and carried out at some distance, passing the instrument fairly through; and a few inches of the silk or cord that may be employed is to be left hanging out from the orifices; the cord is to be daily drawn out and renewed.

Diseases of the eyes.

Inflammation of the eyes is of two species; the one called by systematics, opthalmia membranarum, inflammation of the membranes of the eye; the other, opthalmia tarsi, inflammation of the eye-lid; the latter is a glandular and scrophulous affection. Membranous inflammation is to be subdued by saturnine lotions, by bleeding with leeches on the temples; and if the disorder be violent, and the inflamed vessels very turgid, by cutting the vessels across upon the eye. Light, and all other sources of irritation, it is hardly necessary to observe, should be kept from the eye as much as possible.

Opthalmia tarsi is best treated by rubbing over the lid, when the eye is closed, some one of the active mercurial ointments, of which perhaps the most efficacious is the ung. hydrargyri nitrati of the London Pharmacopeia.

Membranous inflammation, if violent or long continued, is apt to be followed by specks on the cornea; these may sometimes be removed by absorbent remedies, local or general, such as calomel thrown into the eye through a quill, or small quantities taken internally so as to produce a very gentle mercurial action in the system. Sometimes, when the speck on the cornea is very prominent, it may be removed by a small knife. When the membranous excrescence termed pterygium, spreads from the white of the eye over the cornea, a scarification should be made through it entirely round, and at a little distance from, the circumference. After the hemorrhage has subsided, a saturnine lotion is to be applied to the eye.

Inflammation now and then terminates in an abscess of the eye, which confounds the humours, and destroys vision; in this case the matter must be evacuated by an incision into the cornea. Ulcers of the eye may arise from the same causes, constitutional or local, that occasion ulcers in other parts: the general principles of treatment must likewise be the same.

The aqueous humour of the eye sometimes accumulates inordinately, and constitutes a kind of dropsical swelling of the organ; this disease is to be distinguished from abscess by the manner in which it has been produced, by the patient remaining more or less sensible to light, and by the pupil contracting. Dropsy of the eye may be remedied in its early stages by puncturing the under edge of the cornea, or by piercing the schleratic coat just behind the iris. After the operation, saturnine and astringent lotions are to be used.

It is sometimes necessary to puncture the eye, in order to discharge blood that may have been extravasated from its vessels and remain unabsorbed.

When the eye has become cancerous, the whole of it is to be dissected out, free from the lids, if the operation is performed before these parts have become diseased.

Cataract. This is a disorder either of the crystalline lens or of its capsule, preventing the rays of light from falling upon the retina. Cataract usually commences by a dimness of vision, followed by the sensation of particles of dust floating before the eyes, which is at length succeeded by almost total blindness. This disorder is usually without, but is sometimes accompanied with pain. It is distinguishable from the gutta serena by the opaque appearance of the lens, which in the last disorder is not present. In gutta serena the pupils do not contract in a strong light; in the cataract, the contraction of the pupil usually remains. Whether the capsule merely, or the body of the lens, is affected, it is not easy to ascertain.

In the commencement of cataract, advantage has sometimes been experienced from small doses of calomel, hyoscyamus; cicuta and electricity have each been used with supposed benefit. When the disorder is confirmed, it is only to be removed by an operation, by couching or extraction, by forcing the opaque lens down into the vitreous humour, or by taking it entirely out.

Of couching. "The operator is either to be seated with his elbow resting upon the table, or, which is preferred by some, he ought to stand resting his arm upon the side of the patient. The eye being fixed by the speculum, (fig. 19.) or in such a manner as to allow the whole of the cornea and a small portion of the scleortic coat to protrude, a couching needle, (fig. 21.) is to be held in the right hand in the manner of a writing pen, if the left eye be the subject of the operation; the ring and little fingers are to be supported upon the cheek or the temple of the patient; the needle is to be entered in an horizontal direction through the sclerotic coat, a little below the axis of the eye, and about one-fourth of a line behind the edge of the cornea, so as to get entirely behind the iris, to prevent that substance from being wounded. The point of the needle is to be carried forward till it be discovered behind the pupil. The operator is now commonly directed to push the point into the lens, and depress it at once to the bottom of the eye, but in this way the lens either bursts through the capsule at an improper place, or it carries the capsule with it, tearing it from the parts with which it is connected. Instead of this, the needle ought first to be pushed into the lens near its under edge, as Dr. Taylor advises, and then carried some way down into the vitreous humours, so as to clear the way for the lens. It is then to be drawn a little back, and carried to the upper part of the capsule; when, by pressing upon it, the lens, if solid, is to be pushed down by one, or if fluid, by several movements, to the bottom of the vitreous humour. It should then be pushed downwards and outwards, as Mr. Bell directs, so as to leave it in the under and outer side of the eye; where, in case it should rise, the passage of the light would be little obstructed. The needle is then to be withdrawn, the speculum removed, and the eyelids closed; and a compress soaked in a saturnine solution to be applied over them." It is not advisable, in general, to remove the dressings till about eight or ten days after the operation.

Operation of extracting the lens. "The operator takes the knife, (fig. 23.) and holds it in the same way as he does the needle for couching; he then enters the point of it with the edge undermost into the cornea, about the distance of half a line from its connection with the sclerotic coat, and as high as the centre of the pupil; he is then to pass it across the pupil to the inner angle in an horizontal direction, keeping the edge a little outwards, to prevent the iris from being cut; the point is then to be pushed through opposite to where it entered; the under half of the cornea is next to be cut, and at the same distance from the sclerotic with the parts at which the point of the knife went in and came out from the eye. In cutting the under half of the cornea, the pressure of the speculum upon the eye should be gradually lessened; for if the eye be too much compressed, the aqueous humour, with the cataract and part of the vitreous humour, are apt to be forced suddenly out immediately after the incision is made. The operator then takes a flat probe, and raises the flap made in the cornea, while he passes the same instrument, or another probe, (fig. 24.) rough at the extremity, cautiously through the pupil, to scratch an opening in the capsule of the lens. This being done, the eye should be shaded till the lens be extracted, or the eyelids are to be shut, to allow the pupil to be dilated as much as possible; and while in this situation, if a gentle pressure be made upon the eyeball, at either the upper or under edge of the orbit, the cataract will pass through the pupil more readily than it would do when the eyelids are open. If the lens cannot be easily pushed through the opening of the cornea, no violent force should be used, for this would tend much to increase the inflammation. The opening should be enlarged so as to allow the lens to pass out more freely. When the cataract does not come out entire, or when it is found to adhere to the contiguous parts, the end of a small flat probe or a scoop, (fig. 25.) is to be introduced, to remove any detached pieces or adhesions that may be present. The iris sometimes either projects too much into the anterior chamber, or is pushed out through the opening of the cornea. When this happens, it is to be returned to its natural situation by means of the probe already mentioned. Sometimes the opacity is not in the body of the lens, but entirely in the capsule which contains it. The extraction of the lens alone would here answer no useful purpose. Some practitioners attempt to extract first the lens and then the capsule by forceps; others the lens and capsule entire." The after treatment is to be the same as in couching.

A difference of sentiment prevails respecting the superior eligibility of the one or the other of these operations. Among the surgeons of London, the extraction is principally advised.

Of fistula lachrymalis.

An obstruction of the lachrymal sac or duct constitutes this disease; it is divided into four stages; the first is constituted by a mere dilatation of the sac, and is characterised by a tumour between the inner corner of the eye and the nose, attended with a discharge of tears and mucus over the cheek, the integuments being entire, and as yet free from inflammation. In the second stage the swelling is larger, the skin inflamed, and out of the puncta lachrymalia may be now pressed a yellowish purulent fluid. The bursting of the skin forms the third stage of the disorder; in the fourth, the passage from the sac into the nose is obliterated, its inside being ulcerated or fungous, and the bones being carious; it is only then to this last stage that the term fistula can with propriety be applied.

It has been attempted, by the introduction of a probe (fig. 27.) from one of the puncta lachrymalia into the nasal duct, to overcome the obstruction without wounding the integuments: the injection of astringent fluids has likewise been proposed by means of a syringe, (fig. 28.) the pipe of which is also to enter one of the puncta; but these operations are scarcely practicable; and all perhaps that, in the first period of the disorder, ought to be attempted, is frequent pressure with the finger on the tumour; when the disorder advances, and the tumour threatens to burst, an opening should be made into it with a small scalpel, beginning the incision a little above the line from the angle of the eye to the nose, and laying the sac fairly open; the contents of the tumour are then to be pressed out; and by some surgeons we are directed to search for the nasal duct with a probe, and if it can be found, to introduce a piece of catgut, bougie, or lead, bending it downwards so as to preserve it in the passage till the sides of the duct are healed. The wound is to be dressed with wax and oil, and the dressings retained by sticking plaster. When the passage of the duct is secured, the substance that had been introduced is to be withdrawn, and the wound healed.

In the last, or properly fistulous, stage of the disorder, the attempts at cure are attempts to procure a new duct for the passage of the tears, the original one being obliterated. For this purpose the canula of the trocar (fig. 30.) is to be introduced to the under and back part of the lachrymal sac, and retained while the stilette is to be passed into it in an oblique direction downwards and inwards, till it reach the nasal cavity; the perforation of the bones will be perceived by the operation; and the passing of the instrument into the nostrils, is usually followed immediately by the passage of some bloody mucus out of the nose. When the instrument has thus penetrated the spongy bones, it is to be withdrawn from the canula, and a leaden probe or piece of catgut introduced. The canula is now to be removed, one end of the probe is to remain in the new-formed duct, and the other bent so as to secure its retention, and hang over the edge of the wound, which is now to be covered with lint and adhesive plaster. The probe is to be removed almost daily until the new duct is completely callous, when it is entirely to be removed, and the wound healed.

In cases of much constitutional affection, where the disorder treated in the above manner is likely to recur, it has been proposed to introduce a canula of gold, silver, or lead, into the artificial opening, and to heal the skin over it. The instruments used for this purpose are represented in figs. 31, 32, 33.

Of diseases of the teeth.

The causes of tooth-ach are obscure. Caries of the teeth seems to be sometimes a constitutional, at others an entirely local disease. For the preservation of the teeth, they ought to be kept constantly brushed, with a brush simply, or with some powder that is not of an acid nature. For acids, although for a time they cleanse and whiten the teeth, eventually injure their texture: the acidity constitutes the objection to several of the commonly vended dentifrice powders. Tooth-ach when it proceeds from a disease of the tooth itself, only admits of temporary cure by the common applications of opium, camphor, and the warm essential oils. The empirical remedies for diseased teeth are perhaps generally composed of some strong concentrated mineral acid, by which the carious is for a time separated from the sound portion of the tooth.

Extraction of the teeth. Many are by far too liberal in disposing of their teeth: if the first fit of the tooth-ach be endured, the disorder will frequently, for years, or for life, be suspended, and the tooth remain useful, which by a precipitate extraction would have been unnecessarily lost. In some again, there is a tendency, from the fear of the operation, to the other extreme. When a tooth is extensively carious, it ought by all means to be extracted, for the sake of preserving those that are contiguous; and the momentary pain of extraction is trifling in comparison of the multiplied and protracted fits of toooth-ach.

The instruments for extracting teeth operate in a lateral direction: it is indifferent on which side they are forced out, whether outwardly or inwardly, excepting in the instance of the dentes sapientiæ of the lower jaw, which ought invariably to be forced outwards. Before the claw of the instrument is fixed on the tooth, the gum should be separated from it as deep down as possible; the fulcrum of the instrument is to be on the side opposite to that at which the tooth is to be extracted, and with a single turn, which should not be by jerk or violence, but made with a slow, regular movement, the tooth will come out of its socket.

From very violent affections of the teeth, and from other causes of inflammation, the membrane of the antrum maxillare sometimes inflames, and becomes the seat of abscess. The symptoms of this disease are, violent pain in the cheek, and swelling extending upwards towards the nose, the ears, and the eyes; the swelling generally points in the cheek, and sometimes a discharge of matter takes place from the nostrils or the roots of the teeth. This disease is to be cured by making a free opening for the discharge of the matter, either by extracting one of the molares and perforating the antrum with a trocar, (fig. 37.) through the bottom of the socket; or else, without extracting a tooth, the perforation may be made with a tubular instrument through that part of the antrum which projects over the molares. Astringent solutions may be thrown occasionally into the cavity.

Of ranula. An obstruction in the duct of one of the salivary glands sometimes produces a tumour under the tongue, of such a size as to impede the motion of this organ, and at length to threaten suffocation. This tumour is to be laid fully open, and the mouth may afterwards be washed with some astringent solution.

Enlarged tonsils and uvula are not unfrequent occurrences. When these by their size interfere with respiration or swallowing, they are to be removed by ligature in the same manner as polypi. When the enlarged tonsil is of a conical shape, Cheselden's needle (fig 38.) may be employed, which, threaded with a double ligature, is to be pushed through the base of the tumour; the ligature now being taken hold of by a hook is to be pulled forward, divided, and tied, so as that each division shall surround each half of the swelling. This kind of ligature may be employed for an enlarged uvula or for polypi.

Deafness, when consequent upon an inordinate accumulation or hardening of the wax, is best removed by syringing the ear with warm water in which some soap has been dissolved. When deafness arises from mere dryness in the meatus, some drops of sweet oil should be put into the passage. The suppurative discharge from the ears in young children may generally be relieved by some slightly astringent lotion, such as a weak solution of vitriolated zinc or sugar of lead. When deafness is consequent upon loss of nervous power, either local or general, no relief can be expected from these topical applications. Electricity has been tried with apparent benefit in these cases.

Wry neck generally depends upon a preternatural contraction of the mastoid muscle on one side. The muscle in this case to be carefully divided, lest the parts below it be injured. Mr. B. Bell has proposed a machine (fig. 40.) for supporting the head after the division of the muscle, until it unite and regain its power.

Bronchotomy. When the trachea is to be opened, we are directed to make a longitudinal incision, of about an inch and a half, through the skin and cellular substance, commencing at the under end of the thyroid cartilage; the muscles are then to be separated, the operator taking care to avoid the thyroid gland: when the trachea is laid bare, and the bleeding vessels secured, a puncture is to be made with a common lancet between two of the rings of the trachea, of such size as to admit a canula. Dr. Monro directs that a double canula be used, and the inner one withdrawn from time to time, and cleared of the obstructing mucus. He directs the instrument to be fixed by a strap round the neck. As soon as the purposes are accomplished for which an opening was made into the trachea, the canula is to be taken out, and the wound closed by adhesive plaster.

Paracentesis of the thorax. When the chest is opened in order to evacuate purulent matter, or water, from this cavity, an incision should be made with the scalpel through the skin and cellular membrane, between the sixth and seventh ribs, from one to two inches long; and, in the direction of the ribs, the muscles are next to be divided, and the incision made as near as possible to the upper edge of the inferior rib. The pleura now exposed is to be gently opened; if the lungs adhere to the ribs where the incision is made, the fluid will not immediately discharge itself from the opening: in this case, the adhesion may be separated by a blunt probe, or the incision may be carried a little on towards the sternum. When the fluid begins to flow out, a silver canula (fig. 43.) may be introduced into the wound, attached to the patient's body; and being provided with a cork to it, the operator is either to let out the whole of the matter at once, or to draw it off at different times according to the strength of the patient. The wound, after the evacuation of the fluid, is to be kept open for some time.

Paracentesis of the abdomen. Tapping is usually performed by puncturing the abdomen at about midway between the spine of the ilium and the navel. Others direct the opening to be made in the linea alba. An equal pressure is required during this operation upon the belly; such pressure may either be made by bandage, or by the hands of assistants; the part at which the puncture is to be made being drawn a little over the edge of the bed, if the patient be found lying in a horizontal situation, the surgeon fixes the head of the instrument (a trocar) while the fore-finger directs its point; he is then to push it forward till it ceases to meet with resistance. The perforator is now to be taken out, and the water allowed to discharge, while the pressure on the surrounding parts is continued and increased. After the whole of the water is drawn off, the wound may be covered with a pledget of simple ointment, over this may be laid some flannel dipped in spirits, and bandages are now to be applied round the body with firmness. The bandages should not be removed for one or two days succeeding the operation; after this time they may be taken off daily for a little while, and the abdomen rubbed with some stimulant embrocation.

Herniæ. From malconformation, pre-disposition, or accident, the contents of the abdomen may protrude beyond their boundaries, and thus constitute hernia, or rupture. The most usual places of this descent are through the ring of the external oblique muscle, constituting bubonocele or inguinal and scrotal hernia, and hernia congenita, from under the ligament of fallopius or poupart, forming femoral hernia, and from the navel constituting umbilical hernia.

The causes of rupture we have said are either pre-disposition, accident, or malconformation. Where the constitutional tendency is observed, the exciting causes should with solicitude be avoided. These are violent muscular exertion, particularly of those muscles whose action is principally upon the contents of the abdomen, such are especially called into action in violent strainings to procure stool, in fits of coughing, hurried respiration, laughter, &c.

It is hernia congenita alone that immediately follows upon malconformation, strictly speaking. This is occasioned by the protrusion of some portion of the bowels through the passage by which, just previous to birth, the testicles descend from the abdomen into the scrotum: such passage is commonly shortly closed after the descent, and thus the intestine prevented from entering the bag of the testicle. In the case of congenital hernia the opening is preserved.

Herniæ, with the exception of the one just mentioned, are invested with peritoneum, and thus enclosed in a sac; and to whatever extent the protrusion may have taken place, the tumour still forms in a manner a part of the abdominal cavity. Rupture is an improper apellation for the disorder.

It may easily be conceived that parts thus protruded, even independently of the immediate inconvenience with which they are attended, are in no measure free from danger of serious and alarming consequences. We have a large swelling, for instance; a part, in many cases, of the canal, by which the fæces are constantly passing forward to the anus; and this swelling, so disproportionate to the passage through which it has been protruded, that it is only in some situations of the body, when the parts are not full and tense, that in any case, and with duly managed pressure, they can even for a time be made to resume their former and natural situation.

The reduction of hernia ought then, by all means, to be attempted as soon as it is perceived; and future descents prevented by constant and uniform pressure over the part where the displacement had taken place. For the different kinds of trusses used for this purpose, see figs. 42, 43, 44.

When, from neglect on the part of the patient, a hernia is incapable of reduction, and is at the same time free from pain or stricture of any kind, especial care should be observed in avoiding a repetition of the causes which produced the disease. The alvine discharges are to be regularly maintained, and all violent exertions guarded against; and, with due care, an irreducible and increasing hernia often continues through life without any impediment in the functions, or any interruption in the communication between the protruded and contained portions of the abdominal contents.

The dangerous symptoms in herniæ originate either from spasmodiac stricture of the aperture through which the sac and its contents have passed, or from distention and inflammation of the parts protruded: in this last case, indeed, the symytoms may be attributed to stricture; for the opening, although of sufficient size to allow of the communication between the tumour and the abdominal cavity previous to their falling into disease, now that the contents of the tumour are preternaturally enlarged and inflamed, becomes too narrow for such communication; its unyielding edges form a stricture on the inflamed vessels, and thus increase the inflammation and its consequences. The disorder is now called strangulated hernia. The signs of approaching strangulation are the following: pain in the tumour, an unusual uneasy sensation over the whole belly, increased by any exertion of the abdominal muscles, costiveness, quick and hard pulse, nausea, vomiting, an increase and extension of the pain, greater tenseness in the abdomen, extreme anxiety, and other symptoms of peritoneal inflammation.

These symptoms demand speedy remedies; when the inflammation and pain are already too violent to admit of attempts to reduce the rupture, they should be, if possible, subdued by fomentations over the tumour, and the whole of the abdomen, by the injection of clysters, by warm bathing, and by topical and general blood-letting. The return of the bowels should as soon as possible be attempted, for inflammation may have been present for some time without so much of stricture on the ring having been induced as to prevent reduction, if properly regulated. The patient should be placed on the side opposite the hernia, with his pelvis and lower limbs raised, in order to relax the muscles; the tumour is then to be grasped, and pressure made with the fingers in a direction upwards, and a little inwards towards the crural arch, if the hernia be of the thigh; upwards, and outwards towards the ring, if it be an inguinal or scrotal hernia.

When the inflammatory symptoms continue, the tumour is incapable of reduction, and every appearance proves a complete strangulation of the hernial sac; there is no safety for the patient, unless in the operation which we are now briefly to describe for the inguinal and femoral hernia, which are the principal, and almost only cases of strangulated hernia for which the surgeon is called upon to operate.

Operations for inguinal or scrotal herniæ. The patient should be laid with his body in an almost horizontal position; while the buttocks are somewhat elevated, the thighs are to be raised, and secured by assistants; the parts are first to be shaved, an incision is then to be made with a scalpel through the skin and cellular texture, commencing about an inch above the tumour, and carrying it down some way below the abdominal ring; the ring being thus exposed, a directory is to be introduced between it and the sac, in a direction upwards and outwards. A blunt pointed bistuory is to be inserted in the groove of the directory, and the ring dilated by this instrument till the point of the finger can be introduced; while the surgeon makes the dilatation of the ring sufficient to reduce the hernia, he must be careful of not dilating too freely, lest the bowels be again forced down. The stricture being thus relieved, the protruding intestines are to be returned, the outer wound closed with stitches, and proper bandages applied. When the wound has cicatrized, a truss should be worn.

The operation for femoral herniæ is performed much in the same manner. Here the stricture is from the ligament of the thigh, which, after the sac has been opened, is to be divided to the requisite extent.

Hydrocele. Hydrocele, or dropsy of the scrotum, is either encysted or anasarcous; either diffused through the cellular membrane, or contained in the tunica vaginalis. The anasarcous hydrocele is distinguished from the encysted by the general spreading of the tumour, by its comparatively rapid progress; and although it sometimes depends upon a topical cause, by its being more usually connected with general dropsy. Anasarcous hydrocele is treated by scarifications, or punctures; but unless the dropsical tendency be counteracted by general remedies, much advantage is not to be expected from either.

Hydrocele of the vaginal coat generally first comes on with a sense of fulness about the inferior part of the testicle, which gradually becomes more tense, and rises higher in the body of the testicle: the increase of the swelling sometimes occasions the penis almost to disappear. The tumour throughout is scarcely attended with any pain; it is usually, but not invariably, transparent; its transparency and fluctuating feel, indeed, have been made a criterion to distinguish this from scrotal hernia; but such distinction is formed with more accuracy by the manner in which the disorder has commenced and proceeded, viz. from below, upwards; (the contrary is the case with herniæ) and by no degree of pressure making the swelling to disappear.

The tunica vaginalis may be punctured, and the water drawn off as in other species of dropsy; but this operation affords only a temporary, not a radical cure. The radical treatment consists in not merely evacuating the water from, but causing an irritation between the vaginal and albugineous coats of the testicle, to make them adhere, and thus obliterate the cavity. This is effected by incision, by caustic, or by injection; the last of which, recommended by Mr. Earle, is now, on account of its mildness and safety, very generally practised. The water is first drawn off by a trocar passed into the under and fore part of the tumour; the canula of which is still left in the orifice, the operator securing it with one hand, passes the tube of an elastic bag (filled with red wine somewhat diluted) directly through the canula; he then injects the contents of the bag into the cavity, leaves the tube of the instrument, which is provided with a stop-cock, in the canula, by which the injected fluid is retained. This, after remaining about five or six minutes, is to be taken out, and the fluid suffered to discharge itself through the canula.

The wound in the testicle is now to be covered with a pledgit of lint; the testicle itself is to be supported in a suspensary bandage, and the patient confined to his bed for some days. After this method of treatment, hydrocele is apt to return, but the operation can then be repeated.

The spermatic cord is subject to hydrocele, both of the anasarcous and encysted kind. The latter is sometimes confounded with hernia, but may be distinguished from it by the tumour commencing at some distance down the cord, though it is still above the testicle, which is not the case in the hydrocele of the tunica vaginalis. This swelling may likewise be distinguished from herniæ by its not being altered in size from any posture or pressure. When the tumour becomes large, the palliative, or radical cure, as in the vaginal hydrocele, must be resorted to.

Varicocele is an unusual distension of the scrotal veins. Circocele, the same affection of the spermatic cord. Spermatocele is a disordered distension of the vas deferens and epidydimis. Rheumatocele is a distension of the scrotum from a collection of air.

These several affections arise from local or constitutional derangements, by remedying which they are relieved or cured.

Sarcocele is a schirrous enlargement of the testicle, like other cancerous affections (for this disorder, sooner or later, commonly terminates in open ulcer), it is sometimes produced by obvious causes, at others it commences imperceptibly. Sometimes it remains in a schirrous state for a long time; at others, especially when the subject of the disorder is advanced in years, it soon breaks out into open cancer.

When for this affection it becomes necessary to extirpate the testicle, the operation is to be performed by making first an incision some way above the abdominal rings, which is to be carried through the adipose membrane to the bottom of the scrotum. A firm waxed ligature is to be passed round the spermatic cord, near the ring; the vessels are then to be tied by a running knot, and divided at a little distance below the ligature. The testicle and cord are to be removed by dissecting from above downwards, with the common scalpel. The spermatic arteries and veins are then to be taken up with the tenaculum, and ligatures passed round them; the ligature round the body of the cord being slackened, the edges of the wound are now to be brought as accurately together as possible, and secured by adhesive plaster, leaving the ligatures hanging out of the wound. The compress of linen and a T bandage are to be applied over the whole.

Inflammation is to be as much as possible prevented by keeping the dressings moistened with a saturnine lotion, but the wound is not to be examined until about four or five days from the operation.

Of stone in the bladder.

A disposition to calculary concretions very often displays itself in early life. Large stones have been extracted from the bladder of very young subjects. Most commonly, however, life has considerably advanced before these concretions form at least to any perceptible extent, either in the kidneys or in the bladder. The symptoms of stone are irregular. One of the first sensations is often an uneasiness referred to the point of the urethra, which is more observable during the passage of the urine. This sensation appears in a manner to increase the desire to make water, which is often discharged with difficulty, and only by drops. Sometimes a constant dull pain is experienced in the region of the pubis: at other times the pain is more severe, and not continued. Exercise, especially riding on horseback, increases the symptoms. When the calculus is secreted in the kidneys, pain is felt in the loins, which frequently passes along towards the bladder. Such are the symptoms by which the existence of stone may be without much hesitation decided upon. When small concretions are thrown out of the bladder with the urine, the nature of the complaint is of course unequivocal.

When there is room for doubt, a sound (fig. 50) is to be introduced into the bladder. This instrument, previously to its introduction, should be moistened with oil. The surgeon is to lay hold of the penis with his left hand, while with his right he introduces it with its concave side turned towards the belly; the left hand is now to draw the penis gently forward, and upon the instrument, which is thus gradually inserted into the bladder. If the sound drop immediately upon the stone, the surgeon will feel a tremulous motion. In this, however, he must be careful that he is not deceived. If the instrument have not, at its first introduction, hit upon the stone, it is to be moved in various directions, or the finger may be passed into the anus, or the body of the patient placed in different postures. Even if after these trials, the existence of stone does not appear obvious from sounding, the operation may in a day or two be repeated.

To dissolve stone in the bladder various expedients have been practised, but without success. All that art has hitherto been able to accomplish, is in some measure to obviate the constitutional tendency towards its production, and nothing appears more effectually to operate in this manner than a long continued use of vegetable or mineral alkali, saturated with carbonic acid. (See MATERIA MEDICA and PHARMACY). The pain of stone may sometimes be temporarily relieved by opiates and other antispasmodics, as well as by anodyne fomentations.

Of the operation for extracting stone. (Lithotomy). Two methods only of performing this operation are in the present day spoken of: the one, the high; the other, the lateral operation; and, indeed, the former, which consists of making an incision into the bladder above the pubes, is almost entirely laid aside. It cannot be done without wounding the peritoneum, and, consequently, endangering inflammation of this membrane, the mischiefs from which have been already expatiated on. See the section on wounds.

The lateral operation was first performed by Frere Jacques, a French priest. It was practised and improved by Cheselden, and has recently undergone some alterations.

The patient, properly prepared by laxatives, enemas; &c. without being too much reduced, should be directed to retain his urine some hours previous to the operation. The perinæum and neighbouring parts are to be shaved.

A table, a little more than three feet in height, is to be covered with blankets, pillows, &c. upon which the patient is to be laid, and secured in the following manner: Two pieces of broad tape, about five feet long, are to be doubled, and a noose formed upon them, to be passed over the patient's wrists; the patient is then to lay hold of the middle of his foot upon the outside; one end of the tape is to be passed round the hand and foot, and the other round the ancle and hand, and the turns repeated in the reverse way; each hand and foot is then to be tied; the buttocks are to be brought an inch or two over the edge of the table, and by pillows to be raised higher than the shoulders. One pillow should be placed under the patient's head.

The surgeon is now to introduce a grooved staff (fig. 51) through the urethra into the bladder, with this he feels the stone; he then inclines the staff obliquely over the right groin, so that its convex part may be felt in the perinæum, on the left of the raphæ. He then fixes it, and gives it to an assistant, who holding it with his right hand, is to press it gently, until, with his left hand, he raises and supports the scrotum. The operator, now seated or kneeling between the patient's thighs, makes an incision with a convex-edged scalpel through the skin and cellular texture, immediately below the symphisis pubis, which is just under the scrotum, and where the crus penis and bulb of the urethra meet; and on the left side of the raphæ, and in a slanting direction, continues it downwards and outwards to the space between the anus and tuber of the ischium, terminating somewhat lower than the base of that process. As soon as the integuments are thus divided, two fingers of the left hand are to be introduced, with one keeping back the lips of the wound next the raphæ, and with the other pressing down the rectum. The surgeon should be particularly careful not to cut the crus of the penis, which can be easily felt and separated with one of the fingers at their under part. The surgeon now makes a second incision almost in the same direction as the first, but rather nearer the raphæ and anus. The transversalis penis will by this second incision be divided, with as much of the levator ani and cellular texture as will make the prostate gland perceptible to the finger.

The operator now has a view of the membranous portion of the urethra; he is to seek the groove of the staff with the fore finger of the left hand, the point of which is to be pressed along from the bulb of the urethra to the prostate gland. It is to be kept there, and turning the edge of the scalpel upwards, he cuts upon the groove of the staff, and divides freely the membranous part of the urethra, from the prostate gland to the bulb, till the staff can be perceived perfectly bare, and the point of the finger admitted.

The prostate and neck of the bladder are now to be divided, which may be done by a scalpel, but the gorget (51) is more usually employed. The membranous part of the urethra being divided, and the fore finger retained in its position, the point of the gorget, previously adapted to the groove, is to be directed along the nail of the finger, which will serve to conduct it into the groove of the staff; to this particular attention is to be given. The operator now rises, takes the staff from the assistant, raises it to nearly a right angle, and presses the concave part against the symphisis pubis; again satisfies himself that the beak of the gorget is in the groove of the staff, and then pushes on the instrument till its point slips from the groove into the bladder; further than this the gorget is not to be carried, lest the opposite side of the bladder be wounded. The entrance of the gorget into the bladder will be shewn by the intermediate discharge of the urine from the wound; the staff is now to be withdrawn, and the finger pushed up along the gorget to search for the stone, that the manner of introducing the forceps may be known; at least that the finger serves to dilate the wound in the bladder. A pair of forceps (fig. 52) are now to be introduced with their blades shut close, and the gorget is then to be drawn slowly away in the same direction in which it entered. The handles of the forceps are now to be depressed till they are nearly horizontal; one blade is to be directed towards the symphisis pubis, when the stone is touched, the blades of the forceps are to be opened and moved in various directions, so as to lay hold of the stone; if the operator find a difficulty in doing this, the finger may be introduced into the rectum, and that part of the bladder which may lodge the stone, elevated. If the forceps happen to grasp the stone, in a direction inconvenient for its extraction, it should be permitted again to slip out of the blades. The stone should be extracted slowly. When it has broken in the bladder, or is in detached pieces, the scoop (fig. 53), or finger may be introduced to remove the smaller fragments. Sometimes it is necessary to inject the wound with warm water, and raise the patient's body, in order to wash out some of the remaining concretions.

When any considerable artery bleeds, it is, if possible, to be taken up with a ligature; if this cannot be done, pressure is to be made on the wound with a firm roller.

When the operation is over, the pelvis of the patient should be placed lower than the body, in order to preserve the wound in a depending posture, to facilitate the discharge of blood. When the bleeding has subsided, the bandages are to be untied, a piece of dry lint put between the lips of the wound, which is to be often renewed, and the thighs are to be brought together. The patient is then to be laid in a bed, with the pelvis low, a large dose of laudanum given; and when much pain is afterwards complained of in the abdomen, anodynes are to be given by the mouth and by enema, and fomentations, with bladders of warm water, are to be applied to the pubes. Sometimes after the operation of lithotomy, the wound will be healed in a month; at other times, even if the operation be successful, the patient will be confined for three or four months.

Incontinence of urine. This may arise from various causes; loss of power in the sphincter of the bladder, irritation about the neck of this organ, laceration of its coats, or pressure from the uterus in advanced stages of pregnancy, are circumstances which may be conceived fully adequate to produce an incontinence or suppression of urine.

When a suppression of urine arises from deficient power in the bladder to expel its contents, the catheter (figs. 75 and 76) is to be introduced in the same manner as the sound, in order to draw off the water; in cases likewise of suppression from the pressure of the gravid uterus, the catheter is often employed with much advantage.

When the urine is retained in consequence of irritation and inflammation in the neck of the bladder, the disorder is violent and alarming; it is characterised by the ordinary symptoms of inflammation, attended with an extreme pain and much swelling of the affected parts, so that the catheter cannot be introduced. Treatment: Topical and general blood-letting, anodyne fomentation, opiates in large dose; injections into the rectum of warm water, warm bath.

If the disorder, notwithstanding these means, continues, and every attempt has failed of introducing the catheter, a puncture must be made into the bladder; this operation is by some recommended to be performed above the pubis, by introducing a lancet-pointed trocar of two inches long, about an inch and a half above the pubes directly into the bladder, and withdrawing the stileete to permit the urine to flow through the canula; to the canula a cock is to be fitted, in order that the urinary discharge may afterwards not be continual, and by drops, but at intervals.

When the puncture is made from the perineum, the trocar must be introduced at a little distance from the rapha perinei, and passed into the bladder, a little to the upper and outer side of the prostate.

Fistula in perinæo. A sinuous ulcer in the perineum may be produced by wounds in the bladder, or neighbouring parts, or may arise from inflammation of these parts, common, venereal, or cancerous. When the complaint is local, it is to be treated by incision in the manner of other fistulous ulcers, and dressed with emollient applications, or with poultices, according to the nature and degree of the inflammation and discharge.

Fistula in ano. This is a sinuous ulcer in or near the rectum. It is called complete, when it has an external opening in the integuments, independant of the gut, while it at the same time communicates with the gut. When there is no actual communication of the ulcer with the rectum, it is called an incomplete fistula; and when without any external opening, the ulcer communicates with the gut, it is denominated occult.

Fistulous ulcers near the rectum, may be produced by any local causes of irritation; they frequently follow upon the inflammation produced by obstinate hæmorrhoidal affections. Piles, indeed, are perhaps the most common source of fistula in ano. These are to be remedied by laxatives of a bland and oily nature, by sitting over warm water as the best means of fomenting the parts; and if the pain and swelling are considerable, by the application of leeches upon the tumour: such applications are principally suited to what are termed blind piles. When the disorder is accompanied by a discharge of blood from the anus in an excessive degree, cold and astringent are to take place of warm and emollient applications, such as solutions of sugar of lead, or the simple application of cold water; while costiveness, even in the case of bleeding piles, is to be carefully guarded against, by laxatives: chalybeates internally will often be attended with much advantage. The tinctura ferri muriati of the London pharmacopœia, has been given as a preventive of piles, with much apparent benefit. In the treatment of the complaint, it ought always to be examined, whether it acknowledges a local or a general cause, and whether the hæmorrhoidal disposition depends upon debility, which is often the case, and is then only to be combated by tonic agents.

When an abscess has formed in or about the rectum, and the tumour points externally, a free incision ought to be made into its most depending part, in order to discharge the matter as speedily as possible; the wound is then to be covered with soft linen, upon which is spread some simple mild ointment; and if the surrounding parts are much inflamed, a large emollient poultice laid over the dressing.

When the abscess has been permitted to open itself either externally or internally, and has degenerated into a sinuous ulcer, which is known by the nature of the discharge, the direction of the sinus or sinuses must be ascertained, by feeling with the finger in the anus; when their course is ascertained, a free incision is to be made along their whole length; the patient is to be placed so that his body shall lean upon a table or a chair; the surgeon is to introduce his finger, previously oiled, into the rectum. A crooked probe-pointed bistoury is then to be inserted into the fistula, and pushed against the finger in the rectum; the instrument is now brought downwards, the sphincter of the anus divided, and the sinus thus laid open. When the fistula is occult, it is necessary to make an artificial opening, previous to the passing of the bistoury. After the sinus or sinuses have thus been laid open, pledgets of lint or soft linen spread with simple ointment, are to be gently insinuated into the wound, and a compress of soft linen applied over the surface, and kept there by bandage. The dressings during the cure are to be often renewed, at least once in twenty-four hours.

Abscess will sometimes form slowly in the rectum, and discharge its contents without any fistulous ulcers following. In these cases, after the discharge of the matter, much advantage is often found in the use, for some time, of astringent and detergent injections, such as of lime-water: which the patient himself, by means of a syringe contrived for the purpose, may with ease and safety inject.

SURIANA, a genus of the decandria pentagynia class of plants, the corolla of which consists of five petals, obversely ovated, patent, and of the length of the cup: there is no pericarpium except the crusts of the seeds, which are five in number, and roundish. It is a native of South America. There is but one species.

SUR-REBUTTER, a second rebutter.

SUR-REJOINDER. As a rejoinder is the defendant's answer to the replication of the plaintiff, so a sur-rejoinder is the plaintiff's answer to the defendant's rejoinder. Wood's Inst. 586.

SURRENDER, a deed or instrument, testifying that the particular tenant of lands or tenements for life, or years, does sufficiently consent and agree, that he who has the next or immediate remainder or reversion thereof, shall also have the present estate of the same in possession; and that he yields and gives up the same to him; for every surrenderer ought forthwith to give possession of the things surrendered. West. Sym.

SURROGATE, one who is substituted or appointed in the room of another; as the bishop or chancellor's surrogate.

SURSOLID, or SURDESOLID, in arithmetic and algebra, the fifth power, or fourth multiplication of any number or quantity considered as a root.

SURSOLID PROBLEM, in mathematics, is that which cannot be resolved but by curves of a higher nature than a conic section, *e. gr.* in order to describe a regular endecagon, or figure of eleven sides in a circle, it is required to describe an isosceles triangle on a right line given, whose angles at the base shall be quintuple to that at the vertex; which may easily be done by the intersection of a quadratrix, or any other curve of the second gender.

SURVEYING OF LAND. Surveying, or the measuring of land, is by some supposed to have had its origin in Egypt, and that, more especially, on the banks of the Nile; the inundations of which are said to have obscured the landmarks which the land-owners yearly made between their neighbours' property and their own; and to avoid this annual inconvenience, it was found necessary to devise some plans of form and dimensions which they could employ after every inundation. Such was the opinion of Herodotus, Proclus, and others, which has been continued down to the present age: but it is not our intention to justify such opinion, and we are rather disposed to countenance a position laid down by a modern traveller (Mr. Brown) who has spent much time on the borders of the Nile. He tells us, in Upper Egypt the river is confined by high banks, which prevent any inundation of the adjacent country: and so also in Lower Egypt, except at the extremities of the Delta, where the water of the Nile is never more than a few feet below the surface of the land, and where, of course, the inundations take place; here, however, the country is, as may be expected, without inhabitants.—But wherever the origin of this science might have been, the usefulness thereof is, now-a-days, well known and appreciated.

Geometry is the foundation of land-measuring; and we shall proceed to the most practical rules for finding the areas of such geometrical figures as occur in surveying.

Square. The area of this figure is found by squaring the length of either of its sides, or by multiplying the base side by its perpendicular: as in Plate Surveying, fig 1, AB^2 is therefore = the area. So also, $AB \times BC$ = the area.

Parallelogram, rectangled. The area hereof is found by multiplying the length by the breadth; as $AB \times AD$ = the area. See fig. 2.

Rhombus, or Rhomboides. Multiply the base by the perpendicular height: thus, in fig. 3, $AB \times ED$ = the area.

Also, when two sides and their included angle are given, the product of those sides multiplied by the natural sine of the angle = area: that is, $AB \times AC \times$ nat. *s.* $\angle A$ = area.

*** The angles of a regular rhombus are each 60°; those of a rhomboides may be more or less.

Triangle. Multiply the base by a perpendicular demitted from the opposite angle; half the product is the area; $\frac{AB \times PC}{2}$ = area. (Fig. 4.)

Also, when all the sides are given, from half the sum of the three sides subtract each side severally: multiply the half sum and the three remainders continually together; the square-root of the last product will be the area; that is,

$$\sqrt{\frac{a+b+c}{2} \times \overline{\frac{a+b+c}{2}-a} \times \overline{\frac{a+b+c}{2}-b} \times \overline{\frac{a+b+c}{2}-c}} = \text{the area,}$$

where a, b, and c, denote the three sides.

Otherwise, when two sides and their included angle are given, multiply the two sides together, and that product by the natural sine of the angle; half this last product = the area: that is, $\frac{AB \times AC \text{ nat. } s. \text{ of } \angle A}{2}$ = area.

Tropezium. Divide it into two parts by a diagonal line; demit perpendiculars from the other angles. Multiply the diagonal by the sum of the two perpendiculars: half the product = area; (fig. 5.) that is, $\frac{AC \times De + Bf}{2}$ = area.

Otherwise, where two diagonals and the angle of their intersection are given, multiply the product of the diagonals by the nat. *s.* of the angle of intersection, and half this product will be area (fig. 6;) that is, $\frac{AC \times DB \times \text{nat. } s. \angle E}{2}$.

Or, when it can be inscribed in a circle, and the sides are given; from half the sum of the sides subtract each side severally; multiply the four remainders continually together, and the square-root of the last product will be = area; (fig. 7), that is,

$$\sqrt{\overline{\frac{a+b+c+d}{2}-a} \times \overline{\frac{a+b+c+d}{2}-b} \times \overline{\frac{a+b+c+d}{2}-c} \times \overline{\frac{a+b+c+d}{2}-d}}$$

= area.

Trapezoid. Multiply half the sum of the parallel sides by the distance between them; and the product = area: (fig. 8.)

$$\frac{AD + BC}{2} \times AB = \text{area.}$$

Regular Polygon. When a side and a perpendicular demitted from the centre are given, half the perimeter multiplied by the perpendicular = area: (fig. 9.)

$$\frac{AB + BD + DE + EF + FA}{2} \times G = \text{area.}$$

When a side only is given, the square of the side multiplied by the tabular number or multiplier below = area.

That is, $AB^2 \times$ tab. num. = area.

POLYGON TABLE.

No of Sides.	NAMES.	Tabular Multiplier.
3	Equilateral Triangle	0.433013
4	Square - -	1.000000
5	Pentagon - -	1.720477
6	Hexagon - -	2.598076
7	Heptagon - -	3.633912
8	Octagon - -	4.828427
9	Nonagon - -	6.181824
10	Decagon - -	7.694209
11	Undecagon - -	9.365641
12	Duodecagon - -	11.196152

Circle. The square of the diameter multiplied by .7854 = area; (fig. 10.) *i. e.* $AB^2 \times .7854 =$

area; or, half the circumference multiplied by the radius = area; viz. $AaB \times Ab$ = area.

Circular Ring. Between two concentric circles multiply the sum of the diameters by their difference, and that product by .7854, and the half product = area: (fig. 11.)

$$\overline{AC + DB} \times \overline{AC - DB} \times .7854 = \text{area.}$$

Segment of a Circle, or other *curvilineal figure.* Divide the line OP (fig. 12.) into any even number of equal parts, as O*a*, *ab*, *bc*, &c.; and let perpendiculars be raised from these points. Put B for the sum of *a*2, *c*4, and other even ordinates, and C for the sum of the others; then four times B × twice C, × the common distance between the ordinates, = three times the area: that is, $\frac{4B + 2C}{3} \times D$ (the common distance) = area.

A mean breadth may readily be found, by dividing the whole measure of the ordinates by the number of them, accounting the ends parts of such number; which mean breadth multiplied by the length, will be = area.

Ellipse. Multiply continually together the two axes and the decimal .7854, and the product = area; viz. AC × BD × .7854 = area. (fig. 13.)

All pieces of land are found to be of some one of the forms before described, or composed of two or more of them; and the general rule for finding the content of any such compounded figure is, to divide it into as many of the foregoing simple figures as the case requires; to measure such lines and angles in the field as may be necessary to determine the content of each single figure; and the sum of the whole will be = area.

The Chain. The most general instrument which a land-surveyor employs, is the chain.—Chains of sundry lengths and dimensions were invented in former days; but that which was most approved of, and is now in general use, was invented by the Rev. *Edmund Gunter*, about 180 years since, and is composed of 100 links of strong iron wire, each link 7.92 inches; consequently the whole chain is 22 yards, or 4 poles in length. Hence it appears to be peculiarly well adapted to the measuring of land; as 10 square chains (that is, 10 chains in length and 1 in breadth, or 5 in length and 2 in breadth, or of any other dimensions in such proportion), are exactly an acre.

The accompaniments to the measuring-chain are a staff or rod, of the tenth part of a chain, called an off-set staff, divided into ten parts, answering to ten links of the chain, by which short distances are measured; to which staff a rectangular cross may be affixed, to set off the direction of lines perpendicular to a general line. Picket staves to set up in the angles of fields are necessary; and ten arrows of strong wire, which are employed by the measurer's assistant at each chain's length.

The dimensions of all lines on the land are taken in chains, or, rather, the links of a chain; and the contents are found in square acres, roods, and perches. The acre, we have before observed, contains 4 square roods; a rood contains 40 square perches. In one square acre are 100,000 square links; in a square rood are 25,000 square links; and in a square perch are 625 square links.

By an ordinance of the 35th of Edw. I., as well as by a statute of the 34th of Hen. VIII., it is ordered, that the perch should be $16\frac{1}{2}$ feet; but custom, however, permits perches of different lengths to prevail, in sundry parts of the kingdom: for instance, in Lancashire the customary perch is 21 feet in length; in Cheshire and Staffordshire, 24 feet; in Dorsetshire, $15\frac{1}{2}$ feet; in Somerset and Devon, 15 feet; and in Cornwall the customary perch is 18 feet.

To reduce the statute measure to either of the customary measures, the following rules will apply:—first, if the customary is smaller than the statute, as the Devonshire for instance, say, as the square of 15 is to an acre, or number of statute acres, so is the square of 16.5 to the number of customary acres:—secondly, if the customary is the larger measure, as the Cheshire for instance, say, as the square of 24 is to an acre, or number of acres, so is the square of $16\frac{1}{4}$ to the number of acres customary.

Before a measurer begins his work in the field, he should consider what lines are necessary to be measured for obtaining the content; taking such as require the least walking forward and backward.

Having carefully measured such lines as will reduce the field to some of the simple figures before-mentioned, with such of their measuring lines as may be necessary, he will be enabled to find the content of each part, by the rules laid down in the former part of this article.

We would observe, that a measurer may divide the same field different ways, and obtain the content thereof by each. For instance, the field ABCDE (fig. 14), may be divided into a trapezium ABCD, and a triangle ADE.

Or, it may be divided into four triangles, as in fig. 15.

It may also be divided into four triangles AE*a*, ED*b*, C*de*, and B*cd*, and two trapezoids D*bde*, and AB*ac*; as in fig. 16.

Or, into three triangles AE*a*, EBC, BC*c*, and one trapezoid A*a*B*c*; as in fig. 17.

Land-measurers are much in the practice of taking such lines only in the field as will enable them to draw a geometrical plot thereof by some scale of equal parts; and by taking such measure-lines on the plot, by the same scale, they calculate the content with less trouble than by taking all such measure-lines in the field, as may be necessary to reduce the same to triangles, trapezia, or other simple figures.

The calculations for the quantity of land in the same field, by the four respective methods of taking the dimensions, will stand as follow:

Fig. 14.

$$\text{Trapezium ABCD} = \frac{\overline{Bb + Dc} \times AC}{2}$$

$$= \frac{\overline{460 + 440} \times 1020}{2} = 459000$$

$$\text{Triangle ADE} = \frac{AD \times Ea}{2} =$$

$$\frac{780 \times 251}{2} = 97890$$

5.56890

2.2756

11.024

5 acr. 2 rds. 11 per. for the answer.

It is unnecessary to divide the square links of each small part by 2; as the double content may be carried on, and the aggregate, from thence arising, be divided by 2, once for all.

Fig. 15.

$$\text{Trapezium AEDC} = \overline{Dc + Aa} \times EC$$

$$= \overline{292 + 330} \times 1020 = 634440$$

$$\text{Triangle ABC} = AC \times Bb =$$

$$1020 \times 470 = 479400$$

We have hitherto confined our consideration to such figures only, whose few sides are straight lines of considerable length; but, as the general boundaries of many pieces of land consist of short indentations, it is necessary to avoid the tediousness of computing the contents of a multitude of small triangles and trapezoids; to find such equalizing lines as shall constitute a triangle, or other figure, of equal area with the sum of all such triangles and trapezoids combined.

Suppose, then, that an irregular boundary of a field is of the form of fig. 18, composed of two triangles and four trapezoids.

Draw the line AB, and at A erect a perpendicular AC.—Lay a parallel ruler from A to *e*, the third point. Move the upper part of the rule to *b*, and note where it cuts the perpendicular, as at 1.—From this point 1, lay the ruler to *d*; bring its lower part down to *c*, and note where it cuts the perpendicular, at 2. From 2 lay the rule to *e*, and move it upwards to *d*, and mark the perpendicular at 3.—From thence lay the rule to *f*, and bring it down to *e*, and mark the perpendicular at 4.—From this point lay the rule to B, and raise it to *f*, and mark the perpendicular at 5.—From 5 draw the line 5B; then will the triangle, AB5, be equal in area to the aggregate of the two triangles and four trapezoids.

Example. Suppose that, on some well graduated scale, the base of the triangle A*gb*, was found to be 185, and perpendicular, *gb*, 110; the base, *gh*, of the adjoining trapezoid 250, and sum of its perpendiculars 160; the base, *hi*, of the next trapezoid is 120, and its perpendiculars 180; the base *ik* 325, and the perpendiculars of that trapezoid 190; the base *kl* of the next trapezoid 300, and the perpendiculars thereof 349; the base of the latter triangle, *l*B, 630, and its perpendicular, *lf*, 289; and that the content of the whole is required.

Suppose also, the content of the triangle ABC, whose base AB, by the same scale, is 1810, and perpendicular AC, is 238, is required.

First. The double of the

From whence it appears, that the content of the new triangle is the same as the aggregate contents of all the original triangles and trapezoids, to within the decimal of a perch.

In working with a chain and its off-set staff, a measurer does well in making a rough sketch in his field-book, large enough to admit his writing down the lengths of all the necessary lines, whether for planning, or for casting off the content without a plan.

Where there is a general base line, with several perpendiculars raised thereon, it may be best to continue the reckoning throughout that line: and, by subtraction, find the intermediate distances between one perpendicular and another.

Example. Suppose from the sketch and dimensions of fig. 19, a true plan and the content of the field were required.

Beginning at A, draw a line towards the tree at the upper end, and thereon prick off the distances, as in the sketch.

At the proper points erect the perpendiculars, according to their respective lengths; and the true figure will be as fig. 20. The whole content may be found, by seeking the separate content of each triangle and trapezoid, from the dimensions given in fig. 19, thus:

The double content of the triangle a =	$350 \times 100 =$	35000
of the trapez. b =	$\overline{350 + 260} \times 200 =$	122000
——— c =	$\overline{260 + 400} \times 60 =$	39600
——— d =	$\overline{400 + 350} \times 490 =$	367500
——— e =	$\overline{350 + 200} \times 250 =$	137500
——— f =	$\overline{300 + 200} \times 400 =$	220000
——— g =	$\overline{250 + 400} \times 500 =$	325000
of the triangle b =	$200 \times 400 =$	80000

Hitherto we have supposed all the measuring-lines to be taken within the fields; but a measurer may sometimes meet with fields so circumstanced, by woody ground, meres of water, &c. as not to admit of the necessary internal lines being taken. Such pieces of land may, however, be measured, by taking surrounding lines, making one or more right angles with each other, and raising perpendiculars from those lines to the angular points of the fields; by which a true plan may be constructed, and from thence the content found, either by equalizing the sides by the parallel ruler, or by deducting the contents of the small parts without, from the general content of the trapezium or surrounding figure: see fig. 21.

Example. A plan of the piece of woody ground 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, and 13, being drawn by a 6-chain scale, the content thereof is required.

The ∠ A being (by the cross) made a right one, and the sides BA and AD being measured, the diagonal BD is readily found by construction; or else, by extracting the root of AB × AD.

This diagonal being a base to the triangle BCD, and the other sides BC and CD measured, that triangle also is readily constructed, and the trapezium completed.

The off-sets being made on the lines of the trapezium, the figure of the piece of wood may be correctly drawn.

Its content may then be obtained, either by equalizing (with the parallel ruler, or otherwise) the lines of the wood, and thus reducing it to a trapezium; or by deducting the content of all the small trapezoids without, from the general content of the outer trapezium, fig 22.

First, by reducing the figure to the trapezium, EFGH.

The lines being straightened, as before directed, the diagonal of this new trapezium, found by the scale, will be 1070, and the sum of the perpendiculars, 1065.

Then, $\frac{\text{EG} \times \overline{\text{EK} + \text{HI}}}{2} = \frac{1032 \times 1060}{2} = 516 \times 1060 = 546910 = $ 5 acres, 1 rood, 34 perches, for the answer.

Secondly, by finding the content of the surrounding trapezium, (fig. 21,) and from thence deducting the aggregate of the outer trapezoids.

To find the triangle ABD, we have, $\frac{\text{AB} \times \text{AD}}{2} = \frac{910 \times 930}{2} = 455 \times 930 = 423150.$

The diagonal $\text{BD} = \sqrt{\text{AB}^2 + \text{AD}^2} = \sqrt{910^2 + 930^2} = 1301.$

Then, the triangle BCD is found thus: $\sqrt{s \times \overline{s-d} \times \overline{s-b} \times \overline{s-c}}$, where a, b, c, stand for the sides, and s for the half sum of those sides.

$a = 1301$
$b = 970$
$c = 830$

2)3101

$1550 = s$, the half sum of the sides.
$s - a = 249$
$s - b = 580$
$s - c = 720$

Then, $\sqrt{1550 \times 249 \times 580 \times 720} = \sqrt{161172720000} = 401463.$

The triangle ABD = 423150
The triangle BCD = 401463

824613 = surrounding trapezium ABCD.

= the aggregate of all the small trapezoids; which taken from 824613 (the content of the surrounding trapezium), leaves 546410, = 5 acres, 1 rood, 34 perches, the content, as before.

Thus far we have applied ourselves to single fields only; but we will now proceed to the measuring of two or more, lying contiguously to each other

Example. From the dimensions given in the sketch, fig. 23, the contents of the fields A and B are required.

Field A $\frac{620 \times \overline{290 \times 1060}}{2} = 482300 = 4$ acres, 3 roods, 11 perches, for the measure thereof.

Field B. $\frac{740 \times 500}{2} = 185000 = 1$ acre, 3 roods, 16 perches, for the content of that field.

As in measuring single fields, various methods are pursued for obtaining the contents; such as general lines with normals, or triangles combined with normals, &c.; so also may the content of each respective field, contained in an estate, be found by like means.

The estate, fig. 24, may be measured by a general line, with normals erected thereon, in manner following; viz.

Beginning at the southern end, a measurer takes his principal line from A towards the tree on the northern limits of his work; and at every necessary point in that line, he sets off such perpendiculars as will lead him to the corners of each field, as in the figure. The dimensions taken in each field being as here given, the content of each may be found in manner following:

Notwithstanding some land-measurers have adopted the foregoing method, of normal lines, for their mode of practice, in making plans of estates, yet the following (by triangles, &c.) seems preferable; being less subject to error, and more facile in operation.

Let us suppose that the small estate, fig. 25, was to be measured, by means of a general triangle, and necessary off-sets; the measurer beginning at A, and measuring towards B, from thence to C, and returning to A, making all necessary off-sets as he goes on; required the true plan, and the measure of each field?

From the following dimensions, to plan the estate:

Az	=	250	*a*1	=	60
1X	=	60	Xz	=	60
A*b*	=	500	*b*2	=	320
A*c*	=	730	*c*3	=	70
A*d*	=	810	*d*4	=	140
A*e*	=	940	*e*5	=	100
AB	=	1500	B*k*	=	210
B*o*	=	250	*o*6	=	120
B*f*	=	320	*f*7	=	100
B*g*	=	390	*g*8	=	70
B*b*	=	480			
B*i*	=	300			
BC	=	1600	*ib*	=	350
C*l*	=	600	*l*9	=	250
C12	=	710			
C*m*	=	800	*m*10	=	160
C*n*	=	950	*n*2	=	370
C*o*	=	1380	*o*14	=	580
CA	=	1400			

The plan of the estate being obtained by these dimensions, other lines must now be drawn in each field, dividing it into such geometrical figures as will most readily give the content; as in fig. 26.

By dividing the fields as here directed, the content of each may be found as follows:

THE PLANE TABLE.

Land-measuring may, in some instances, be expedited by instruments which set off lines in their relative positions, and the angles of their inclination one to another; the most convenient instruments for these purposes, are the Plane-table and the Theodolite.

The Plane, or Plain-table, is composed of a smooth rectangular board, commonly of about 15 inches by 12; around which is a frame, that not only serves to keep the paper smooth on which the plan is to be drawn, but, being graduated into degrees, answering to a central point in the board, the angular bearing of any two lines, issuing from the station where the instrument is placed, may readily be ascertained; or the angle itself may be drawn on the paper.—A magnetic needle and compass-box is fixed to one side of the board, which serves to point out the bearing of any line to the magnetic meridian.—There is, also, a brass index-rule, having sundry scales thereon, and also perpendicular sights at the end used herewith. The whole is supported on a three-legged stand, &c. moveable on a brass ball and socket.

A land-measurer having planted his Plane-table at A, one of the inner angles of the field ABCDE, fig. 27, and from any assumed point on the paper (which may be considered as his station-point on the land) directed his sight along the boundary to B, and also to C, to D, and to E; and, by measuring these lines on the ground, finding them to be as follow, viz.: AB = 665, AC 885, AD 1030, and AE 580; he may make a correct plan of the field and from thence, by drawing other lines on the plan, as heretofore directed, he may calculate the content thereof.

If the other sides of the same field, viz. BC, CD, and DE, &c. (fig. 27), had been measured, either on the ground, or on the plot, the content may be found by Rule 2. for the triangle.

A measurer may take his observations from a point about the middle of a field, as at A, (fig. 28,) and take his angles of bearing to all the corners of the field, and measure the links to each corner, and from thence find the content; for, suppose the ∠ BAC = 105° 0′

∠ CAD = 59 30

∠ DAE = 129 0

∠ EAB = 66 30

And that the line AB = 480

AC = 550

AD = 665

AE = 730, he will have two sides of each triangle, and their included angle, given from whence he may make his plan; and by Rule 3. of triangles, find the content.

A measurer may take two stations in a field, as at A and B, (fig. 29, the distance between which must be carefully measured); he must then from each station direct his sight to the corner of the field, and draw dotted lines till they intersect each other. From the intersections of these dotted lines he must draw the boundary lines to make his plan; in which he must draw such measuring-lines as are necessary to find the content by the scale.

A measurer may take four or more stations in a field, as *abeg*, (fig. 30,) and set up such perpendiculars as are necessary for perfecting the boundary *lmdfbk*; the plan being laid down, the content of the field may be found by scaling.

THE THEODOLITE.

The Theodolite is a circular instrument made of brass, graduated into degrees, &c. on which is an index-limb for taking horizontal angles, surmounted with an arch for vertical angles, and a telescopic sight. It has, usually, spirit-levels to adjust it by; and a compass, for angular bearings, checking the observations by the limb: the whole placed on three legs, and a ball and socket, or half-ball and parallel plates, to set it level.

In all cases of land-measuring, where angles are required to be taken, whether horizontal or vertical, no instrument is so well adapted thereto as the theodolite; its accuracy and dispatch far exceeding all other instruments used for that purpose, especially on large estates, where varieties of boundary, as well as inequality of surface, are met with.

In a single piece of land, the angular observations may all be made from one spot in a field.

In this case, the theodolite being set at the station A, fig. 31, and properly adjusted (as hereafter described), the first observation to the picket-staff at *a*, was = 62° 20′, from the north towards the east, and the length of the line A*a* = 660 links.

The second observation, to *b*, between the south and east, = 152° 0′, and the length of the line A*b* = 960 links.

The third, to *c*, between the south and the west, = 200° 0′, the length 730.

And the fourth observation, to *d*, from the north towards the west, 329° 50′, and the length 599.

From hence, with the help of a protractor, the plan may be drawn.

It is evident, that if from the observation *b*, that of a is subducted, the $\angle\, aAb$ will be found $= 89^\circ\ 40'$.

That if from the observation c, that of b is subducted, the $\angle\, bAc$ will be found $= 48^\circ\ 0'$.

That if from the observation d, that of c is subducted, the $\angle\, cAd$ will be found $= 129^\circ\ 50'$.

And also, that if the circular complement of the observation d (which is $360^\circ - 329^\circ\ 50' = 30^\circ\ 10'$) is added to the observation a, the $\angle\, dAa$ will be found $= 92^\circ\ 30'$.

The whole together making (as it ought) the complete circle 360°.

The content may now be computed by Rule 3 of triangles.

A measurer may take the angle at each corner of a piece of ground, and measure the sides as he goes on, thus:—having set the needle to its 360°, and the limb to its 360°, he found by observation at ⊖ 1, that looking to his picket at ⊖ 2, the limb cut 304°, from the north towards the west, and his needle 124°.—At ⊖ 2, having directed the theodolite to the back station, his observation forward was, on the limb, 45° 30′ from south to west, and on the needle 45° 30′ also. At ⊖ 3, the limb was at 126° 0′, from south to east, and the needle at 306° 0′.—And at ⊖ 4, the limb and needle both were at 216° 0′, from the north to the eastward.

Supposing the lines were found to be 1000 links, 800 links, 1100 links, and 800 links, the plan may be made, and the content found by the scale.

In extensive concerns, where all the fields in an estate or manor are to be measured, large circuits must be taken with the theodolite, and the proceedings carefully noted down in the field-book, the pages of which are divided into three parts; the middle column being for inserting the angular observations, and the progressive distances from station to station, and the points where it may be necessary to set off (with the ten link staff) such short lines as the flexures or angles of boundaries may require. The sides of the page are employed in noting down such off-sets and remarks, on either hand, as may be found necessary, and also in making sketches of side boundaries, where any deviations from a straight line occur. For the more readily sketching such side boundaries, it is necessary to begin at the bottom of the page, and write upwards.

For an example to exemplify the mode of practice with this excellent instrument, we will take the estate, fig. 33, and suppose the measurer to plant his instrument in the road at ⊖ 1, and having duly adjusted it, by setting the head thereof truly horizontal by the spirit levels and adjusting screws; and setting the index part of the limb exactly at 360°, by moving the whole head about until the 360 in the compass-box comes to the line in the north end of the needle, the instrument will thus be completely adjusted: here he is to lock all fast by the screw under the head between the legs.

The instrument thus adjusted, the measurer sends one of his assistants forward, as far as he can conveniently measure a straight line, as at ⊖ 2. Taking then his angle of observation by his telescope, he finds it to be 69° 0′ from the north towards the east, which he enters in his field-book, noting it with N. E. as a memorandum on which side of the meridian it lies. He must now fix his limb to the other part of the head, by a screw for that purpose. His chain-men having laid the chain in a direction to the picket at ⊖ 2, he proceeds to measure this line, making such off-sets to the right and left as may be necessary. At his station he finds, by measuring, on the right, with his off-set staff, that he has the general line of the road-fence at 30 links, and also a corner of 40 links more, and 30 broad: on the left of his station he has an off-set of 10 links. The chain-men proceeding on their line to 300, he finds 25 on the right to be the breadth on that side of the road, where is a gate, and on the left 20, which will determine the breadth of the road at that spot. At 400 he will find 10 on the right, and 20 on the left, to be the breadth. At 760 (the end of that line) he will find 35 on the right, and 15 on the left, to be the breadth; where also he will find a small road branch off to the right. Thus is the first station-line finished.

To this spot (which is his second station) he brings his theodolite, and after setting it level, unlocks the under screw and turns the whole head about, until, through the telescope, he sees the back picket or station-staff. Here again, locking the head of his theodolite, he must unscrew the limb, and turn it about until, through the telescope, he has a view of the picket at ⊖ 3; the angle to which he will find to be 253° 10′ from the north to the eastward, which he will enter in his field-book. Measuring on from ⊖ 2 to ⊖ 3, he will find, at 130 links, that he is come to a turnpike-gate, where the breadths on the right and left are 30 and 15. At 200 he has an off-set of 15 on the left; and a break-off at the right of another road, at 25 from his line, with two other off-sets, as expressed in the field-book. Whereto this road leads, must be noted. At 265 he has off-sets of 30 on the left, and 20 on the right; which ends this station line.

Bringing now his instrument to ⊖ 3, he is to adjust it in the manner we have directed him to do at ⊖ 2, and turning the limb about towards the picket forward, he will find the angle of bearing to be 57° 45′, still from the north to the eastward. At 20 he will find himself opposite to a cross hedge on the left, belonging to the estate he is surveying. At 293 he ends his line of this station; where the off-sets are 5 and 35, as noted in the field-book.

Coming now to ⊖ 4, and having adjusted his theodolite, he finds his next angle = 226° 0′ N. E. At 20 his off-sets are 20 and 15. At 410 they are 15 and 30, where, on the left, is a cross hedge of a backward direction. At 480 his off-sets are 5 and 25, where is another cross hedge. At 750 is a break-in of the fence, and the off-sets are 30 + 15 on the left, and 10 on the right. At 1050 the off-sets are 20 on each hand, and another cross hedge on the left. At 1150 are off-sets on the right of 20 and 20, where stands a house. At 1300 the off-set of 30 on the right terminates the house; and at 5 on the left is a cross hedge of a backward direction:—1350 ends this line, where roads diverge to the right and left.

At ⊖ 5 the instrument being adjusted, the angle is 284° 50′, nearly W. At 50 the off-set to the hedge is 15; at 220 it is also 15, where is a cross hedge, which is the same as was noted at 1050 in the last line. At 320 the off-set is 25. At 350 is the end of this station, where the distance from the fence is 15.

At ⊖ 6 the bearing is 305° 35′ N. W. At 130 the off-set is 30; where a cross hedge goes off to the point noticed at 750 in the line from ⊖ 4 to ⊖ 5. At 160 the line is nearly close to the fence. 210 ends this line.

At ⊖ 7 the angle forward is 106° 25′ N. W. The line is 143 long, with an off-set at the end of 15.

At ⊖ 8 the bearing is 269° 20′ N. W. At 100 and 300 the off-sets are 15 and 10.

The bearing at ⊖ 9 is 70° 45′ S. W. At 30 the measurer finds it expedient to cross the fence, and to proceed within the bounds of the estate. At 90 he has an off-set of 30 to the right, where he crosses a hedge. At 880 he crosses another hedge, having there an off-set of 20. At 940 he has an off-set of 50. At 990 he again crosses the hedge. At 1020 he has an off-set of 20 to the left. At 1040 he again crosses the hedge. At 1080 he comes to the corner of the farm-house; and 1165 ends his line, where is a small curve at the right.

At ⊖ 10 the bearing is 204° 0′ S. W. At 70 is an off-set of 5 on the right At 200 is 15 on the left, and a cross hedge. At 600 is 25 on the left, and 20 + 15 on the right. 690 ends the line, having an off-set of 15 on the right, and the like on the left, where is a cross hedge.

The bearing at ⊖ 11 is 355° 30′ S. E. At 280 is an off-set of 30 on the right, and 10 with a cross hedge on the left. At 400 is an off-set of 30, and a cross hedge at the left; and 470 ends the line, with off-sets of 10 and 20 on the right and left.

At ⊖ 12 the bearing is 155° 0′ S. E. At 60 is a cross hedge. At 219 the off-sets are 10 and 15: and at 229 the measurer comes to a close at ⊖ 1, where he began.

Having thus taken a circuit of this estate, the measurer must proceed to plot off the same by some convenient scale in manner following:

PLOTTING.

The plotting, or making a draught of an estate, from a field-book or other memoranda taken in the field, is thus performed:

The paper, or vellum, on which the plan is to be drawn, must be smoothly laid down on a drawing-board: a line is to be drawn from the bottom to the top, to represent the magnetic meridian.

About the middle part of this line a point is to be made, on which point the centre of the circular protractor is to be laid, the straight edge so placed as to coincide with the meridian line: round, at the edge of the protractor, draw a pencil line. [The protractor is a circular piece of brass, having its edge divided into degrees &c. answerable to the circumference of the theodolite, so that whatever horizontal observation is made with the latter, it may be laid down on paper with the help of this instrument.]

The protractor thus placed, being steadily fixed in that position by pins, or by a lead weight, look in the field-book for the quantity of the ∠ at ⊖ 1, which, in the present case, is stated to be 69° 0′ north-easterly. Look for this degree, on the circular edge of the protractor, and on the paper make a mark, with a fine plotting-pin, at that number; mark it 1, denoting ⊖ 1.

Look in the field-book for the ∠ at ⊖ 2, which, in this case, = 253° 10′, where make a mark, as before.

Thus do with all the other ∠s, until you come to the last station previous to a close on some former part of the work.

All the angles being thus pricked off, remove the protractor.

Consider whereabout the beginning of the work should be placed, so that the whole may come within the compass of the paper laid down; and there make a mark, noting it as ⊖ 1, the beginning of the plot.

Lay the fore edge of the parallel ruler from the central point where the protractor lay, to the mark on the pencilled circle denoted ⊖ 1. Move the fore edge of the parallel ruler until it touches the point determined on for the beginning of the plot.—From thence draw an obscure or pencil line (in the direction mentioned, i. e. in this case, from the north to the eastward) about the length of the whole line of this ⊖, = 760.

Apply a feather-edge scale to this obscure line, the 0 division thereof at the beginning; and prick off every progressive number where any off-sets have been made; as at 300, 400, and 760.

Turn the scale across the line (by some cross division), and prick off the off-sets on each side o the station-line. At 0, or ⊖ 1, the field-book informs us, that on the left hand, at 10 links, is the boundary-line of that side; where is also a small road branching off. On the right hand, the off-set is 30, which, with + 40, goes to the extent of a small nook, that is 40 links broad also. At 300, on the left, is an off-set of 20, and, on the right, another of 25; where also is a gate to be noticed.—At 760 is an off-set on the left of 15; and, on the right, one of 35, where a small road-way branches off. All which off-sets are to be pricked off as you go on. Draw the boundary-lines through these off-set points; and thus the first station will be completed.

Lay, now, the parallel ruler from the centre to the angular point of ⊖ 2: move the limb of the parallel ruler, until it touches the end of the last station; from whence draw another obscure line, from the north, easterly, as noted in the field-book.

Apply the edge of the scale as before, and prick off the numbers 30, 200, and 265.—At 30 links is a toll-gate, where the off-sets are 15 and 30.—At 200, the off-sets are 15 and 25; where, on the right hand, is a short line of hedge of 30 links, and also a lane of 30 links broad, going off at an acute angle.—At 265, the end of this station, the off-sets are 30 and 10.

Lay off the line from ⊖ 3, as before directed, north-easterly.—Prick off the numbers 20 and 293. Opposite 20 is a hedge branching off to the left.—At 293 the off-sets are 35 and 5.

From ⊖ 4 lay off the line north-easterly, and prick off the numbers on that line, as they appear in the field-book, and make the off-sets as follow, viz. At 120 set off 15 and 20. At 410 are 30 and 15, where two hedges branch off nearly in the direction of the side sketches. At 480 the off-sets are 25 and 5, where is a cross hedge on the left. At 150, on the left, is 30 + 15 with a cross hedge; on the right is 10. At 1050, on the left, is 20 with a cross hedge, and 20 on the right. At 1150, on the right, is 20 + 20, where stands a house. At 1300, on the left, is 5 with a cross hedge; on the right is 30 with a road branching from thence.—1350 completes this line.

At ⊖ 5 the work takes another direction, and goes backwards towards the west. Lay the ruler from the centre to this station, and draw the obscure line in the direction mentioned. Prick off the distances and off-sets as in the field-book. Here we have off-sets on one side only, not being now in a road-way.

At ⊖s 6, 7, and 8, set off the lines south-westerly, and prick off the distances and off-sets, as in the field-book.

At 30, in ⊖ 9, a hedge was crossed; as also at 990 and 1040.

Station 10 still bears west of the south; at the end of which we again come into a road-way.

But at ⊖ 11, the direction of the line bears above the south, towards the east; as does that also of ⊖ 12.

At the end of this station, the work comes to a close at ⊖ 1.

After having thus plotted his work, the measurer will have to draw another line, for the true meridian, to the eastward of the former, according to the variation of the magnetic needle, where the estate lies.—On this true meridian line he must place a *fleur de lis*, or some other device, as a north point.—He will also have to give a title to his map; to draw a scale of the proportion he has plotted by; and to give the whole a border.

After this circuit is plotted off, the measurer must fill up the interior by measuring with the chain, and lay each field down in its proper situation and dimensions on the plan.

Having thus a prototype of the estate on paper, he may draw such measuring-lines on his plan as will enable him to calculate the content of each field separately.

SURVIVORSHIP. See LIFE ANNUITIES.

SUS, *hog*, a genus of quadrupeds, of the order belluæ. The generic character is, front teeth in the upper jaw four, converging, in the lower jaw six, projecting; canine teeth, or tusks, in the upper jaw two, rather short; in the lower jaw two, long, exserted; snout truncated, prominent, moveable; feet cloven. This genus is in some points of an ambiguous nature, being allied to the pecora, by its cloven hoofs, and to the feræ, in some degree, by its teeth; yet differing widely from both in many respects. The internal structure of the feet also approaches to that of the digitated quadrupeds, while that of some other parts is peculiar to this genus alone. It may, therefore, be allowed to form at once a link between the cloven-footed, the whole-hoofed, and the digitated quadrupeds.

1. Sus scrofa, common hog. The wild boar, the stock or original of the common domestic hog, is a native of almost all the temperate parts both of Europe and Asia, and is also found in the upper parts of Africa. It is a stranger to the arctic regions, and is not indigenous to the British isles.

The wild boar inhabits woods, living on various kinds of vegetables, viz. roots, mast, acorns, &c. &c. It also occasionally devours animal food. It is, in general, considerably smaller than the domestic hog, and is of a dark brinded grey colour, sometimes blackish; but when only a year or two old, is of a pale rufous or dull yellowish brown cast; and when quite young, is marked by alternate dusky and pale stripes disposed longitudinally on each side the body. Between the bristles, next the skin, is a finer or softer hair, of a kind of woolly or curling nature. The snout is somewhat longer in proportion than that of the domestic animal; but the principal difference is in the superior length and size of the tusks, which are often several inches long, and are capable of inflicting the most severe and fatal wounds.

The hunting of the wild boar forms one of the amusements of the great in some parts of Germany, Poland, &c. and is a chace of some difficulty and danger; not on account of the swiftness, but the ferocity of the animal.

As the wild boar advances in age, after the period of three or four years, he becomes less dangerous, on account of the growth of his tusks, which turn up, or make so large a curve or flexure, as often rather to impede than assist his intentions of wounding with them.

To describe particularly the common or domestic hog would be superfluous. It may be sufficient to observe, that this animal principally differs from the wild boar in size, in having smaller tusks, and larger ears, which are also somewhat pendant, and of a more pointed form. Of all quadrupeds the hog is the most gross in his manners, and has therefore been pretty uniformly considered in all nations as the emblem of impurity. The Jews were strictly enjoined not to eat its flesh; and in many parts of the world, a similar prohibition is still in force; since the Mahometans agree in this respect with the Mosaic institution. In most parts of Europe, on the contrary, it constitutes a principal part of the food of mankind. This animal is of a remarkably prolific nature, being sometimes known to produce as many as twenty at a birth.

The hog was unknown in America, on the discovery of that continent; but since its introduction, appears to flourish there as much as in the old world. The varieties into which the hog occasionally runs, chiefly relate to size and colour. That called the Chinese hog is of a very small size, with a remarkably pendulous belly: its colour is commonly black, and the skin often nearly bare, or less hairy than in the European kinds.

The variety called the Guinea hog is distinguished by having a smaller head than the common hog, with long, slender, sharp-pointed ears, and naked tail reaching to the ground. Its colour is rufous, and its hair softer, shorter, and finer than in other kinds. It is said to be most common in Guinea, and is considered by Linnæus as a distinct species, under the title of sus porcus.

But the most remarkable variety of the hog is that in which the hoofs are entire and undivided. This is a mere accidental variety, which is, however, observed to be more common in some countries than in others, and is, according to Linnæus, not unfrequent in the neighbourhood of Upsal in Sweden. It has been noticed by Aristotle and Pliny, and is said by the former to have been most common in Illyria and Pæonia.

The age of the domestic hog is said to extend from fifteen to twenty-five years, or even more.

2. Sus Æthiopicus, Æthiopian hog. This animal is very much allied in its general appearance to the common hog, but is distinguished by a pair of large, flat, semicircular lobes or wattles, placed beneath the eyes: the snout is also of a much broader form, and is very strong and callous: the ears are large, and very slightly pointed: the tusks in the lower jaw are rather small; but those in the upper jaw are large, sharp, curved, and in the old animal bend upwards in a semicircular manner towards the forehead: there are no fore teeth; their place being supplied by very hard gums: the skin of the face, immediately below the eyes, or above the broad lobes before-mentioned, is loose and wrinkled, and on each side the corners of the mouth is a callous protuberance. The body is of a strong form; the tail slender, slightly flattened, and thinly covered with scattered hairs. The general colour of the whole animal is a dusky or blackish brown.

This species is a native of the hotter parts of Africa, occurring from Sierra Leona to Congo, and to within about two hundred leagues of the Cape of Good Hope. It also occurs in the island of Madagascar.

It is a fierce and dangerous animal, and is said to reside principally in subterraneous recesses which it digs with its nose and hoofs. When attacked or pursued, it rushes on its adversary with great force; and strikes, like the common boar, with its tusks, which are capable of inflicting the most tremendous wounds.

3. Sus Africanus, Cape Verd hog. The Cape Verd hog has been generally confounded with the former animal, from which, however, it appears to differ very considerably; having a head of a much longer and slenderer form, with the upper jaw extending beyond the lower. In the upper jaw are also two cutting teeth, and six in the lower: the tusks are very large and thick, but those of the lower jaw much larger than those of the upper: the ears are rather narrow, pointed, and tufted

with long bristles or hairs: the whole body is also covered with long, weak, or fine bristles, of which those on the shoulders, belly, and thighs, are much longer than on other parts: the tail is thin, and terminates in a longish tuft. The colour of this animal is a palish brown. Its general size is that of a common hog, but it is said sometimes to be found far larger. It is a native of Africa extending from Cape Verd to the Cape of Good Hope. See Plate Nat. Hist. fig. 383.

4. Sus babyroussa. The babyroussa is nearly of the size of a common hog, but of a somewhat longer form, and with more slender limbs, and is covered, instead of bristles, with fine, short, and somewhat woolly hair, of a deep-brown or blackish colour, interspersed with a few bristles on the upper and hinder part of the back. It is also distinguished by the very extraordinary position and form of the upper tusks, which, instead of being situated internally on the edge of the jaw, as in other animals, are placed externally, perforating the skin of the snout, and turning upwards toward the forehead; and as the animal advances in age, become so extremely long and curved as to touch the forehead and continue their curvature downwards, by which means they must of necessity lose their power as offensive weapons: the tusks of the lower jaw are formed as in the rest of the genus, and are also very long, sharp, and curved; but not of equal magnitude with those of the upper. The upper tusks are of a fine hard grain, like that of ivory: the eyes are small; the ears somewhat erect, and pointed: the tail rather long, slender, and tufted at the head with long hairs.

The babyroussa is a gregarious animal, and is found in large herds in many parts of Java, Amboina, and some other Indian islands. Their food is entirely of a vegetable nature, and they often feed on the leaves of trees. When sleeping or resting themselves in a standing posture, they are said often to hook or support themselves by placing the upper tusks across the lower branches of the trees. When pursued they will often plunge into a river, or even into the sea, if near, and can swim with great vigour and facility, and to a vast distance. The voice of the babyroussa is said to resemble that of the common hog, but it occasionally utters also a strong or loud growling note. It is sometimes tamed by the inhabitants of the Indian islands, and the flesh is considered as a wholesome food. See Plate Nat. Hist. fig. 385.

5. Sus tajassu, pecary. The pecary is the only animal of this genus that is a native of the new world, where it is chiefly found in the hottest regions. Its size is considerably smaller than that of a common hog, and it is of a short compact form. The whole animal is thickly covered, on the upper parts, with very strong dark-brown or blackish bristles, each marked by several yellowish-white rings; so that the colour of the whole appears mottled with minute freckles or specks, and round the neck is generally a whitish band or collar. The head is rather large; the snout long; the ears short and upright; the belly nearly naked: there is no tail, and at the lower part of the back, or at some little distance beyond the rump, is a glandular orifice surrounded by strong bristles in a somewhat radiated direction. From the orifice exsudes a strong-scented fluid, and this part has been vulgarly supposed to be the navel of the animal: the tusks in this species are not very large.

The pecary is a gregarious animal, and in its wild state is fierce and dangerous; sometimes attacking the hunters with great vigour, and often destroying the dogs which are employed in its pursuit. It feeds not only on vegetable substances, but occasionally on animals of various kinds, and is particularly an enemy to snakes and other reptiles; attacking and destroying even the rattlesnake, without the least dread or inconvenience, and dexterously skinning it, by holding it between its feet, while it performs that operation with its teeth. It is also remarkable that the common hog, when translated to America, will attack and destroy the rattlesnake. The pecary is considered as an agreeable food; but the dorsal gland must be cut away as soon as the animal is killed: otherwise the whole flesh would be infected with an unpleasant flavour. See Plate Nat. Hist. fig. 386.

SUSPENSION, or Points of Suspension, in mechanics, are those points in the axis or beam of a balance, wherein the weights are applied, or from which they are suspended.

In a law sense, suspension is a species of censure, whereby ecclesiastical persons are forbidden to exercise their office, or to take the profits of their benefices; or when they are prohibited in both of them for a certain time, either in whole or in part. Suspension is also said to relate to the laity, viz. suspensio ab ingressu ecclesiæ, *i. e.* from hearing divine service.

SUTURE. See Surgery.

SWARTZIA, a genus of the class and order polyadelphia polyandria. The calyx is four-leaved; petals single, lateral, flat; legumen one-celled, two-valved; seeds arillated. There are six species, trees of the West Indies.

SWEARING, an offence punishable by several statutes: thus stat. 6 and 7 Will. III. cap. 11. ordains, that if any person shall profanely swear, if he is a labourer, servant, or common soldier, he shall forfeit 1s. to the poor, for the first offence, 2s. for the second, &c.; and any person not a servant, &c. forfeits 2s. for the first offence, 4s. for the second, 6s. for the third, &c. to be levied by distress of goods.

SWEAT. See Perspiration.

Sweating-Sickness, a disease which appeared first in England, in the year 1483. It seized different patients in different manners; for in some it first appeared with a pain in the neck, scapula, legs, or arms; whilst others perceived only a kind of warm vapour, or flatulence, running through those parts. And these symptoms were suddenly succeeded by a profuse sweat, which the patient could not account for. The internal parts became first warm, and were soon after seized with an incredible heat, which thence diffused itself to the extremities of the body. An intolerable thirst, restlessness, and indisposition of the heart, liver, and stomach, were the next symptoms, which were succeeded by an excessive head-ache; a delirium, in which the patient was very talkative; and after these, a kind of extenuation of the body, and an irresistible necessity of sleeping. For preventing this disease, temperance was ordered, and the choice of salutary aliments and drinks, and no crude pot-herbs nor sallads to be used.

SWEEP, in the sea-language, is that part of the mould of a ship, where she begins to compass in at the rung-heads: also, when the hawser is dragged along the bottom of the sea, to recover any thing that is sunk, they call this action sweeping for it.

SWEETS, in the wine trade, denotes any vegetable juice, whether obtained by means of sugar, raisins, or other foreign or domestic fruit, which is added to wines, with a design to improve them.

SWERTIA, *marsh gentian*, a genus of plants belonging to the class of pentandria, and to the order of digynia; and in the natural system ranging under the 20th order, rotaceæ. The corolla is wheel-shaped. There are nectariferous pores at the bases of the segments of the corolla. The capsule is unilocular and bivalve. There are six species. The perennis is a native of England. It is distinguished by radical oval leaves. It flowers in August.

SWIETENIA, *mahogany*, a genus of plants belonging to the class of decandria, and to the order of monogynia; and in the natural system arranged under the 54th order, miscellaneæ. The calyx is quinquefid. There are five petals; the nectarium is cylindrical, supporting the antheræ with its mouth. The capsule is five-celled, woody, and opening at the mouth. The seeds are imbricated and winged. There are three species: the mahogani, which is the principal, is a native of the warmest parts of America, and grows also in the island of Cuba, Jamaica, Hispaniola, and the Bahama islands. It abounded formerly in the low lands of Jamaica, but is now found only on high hills and places difficult of access.

It thrives in most soils, but varies in texture and grain according to the nature of the soil. On rocks it is of a smaller size, but very hard and weighty, of a close grain, and beautifully shaded; while the produce of the low and richer lands is observed to be more light and porous, of a paler colour, and open grain; and that of mixed soils to hold a medium between both. The tree grows very tall and straight, and is usually four feet in diameter; the flowers are of a reddish or saffron colour, and the fruit of an oval form, and about the size of a turkey's egg.

The wood is generally hard, takes a fine polish, and is found to answer better than any other sort in all kinds of cabinet-ware. It is now universally esteemed, and sells at a good price. It is a very strong timber, and answers very well in beams, joists, plank, boards, and shingles; and has been frequently put to those uses in Jamaica in former times. It is said to be used sometimes in ship-building; a purpose for which it is remarkably adapted, if not too costly, being very durable, capable of resisting gun-shots, and burying the shots without splintering.

The seed-vessels are of a curious form, consisting of a large cone splitting into five parts, and disclosing its winged seeds, disposed in the regular manner of those of an apocynum. The seeds being winged, are dispersed on the surface of the ground, where some falling into the chinks of the rocks, strike root; then creep out on the surface, and seek another chink, into which they creep and swell uch a size and strength, that at length the k splits, and is forced to admit of the root's per penetration; and with this little nutri-it the tree increases to a stupendous size few years.

WIMMING, the act of sustaining the y in water, and of moving in it, in which on the air-bladder and fins of fishes bear a considerable part. See AIR-BLAD-R, and FISHES.

WIMMING, as applied to human beings, he art of balancing the body on or near surface of the water, and of making a gress through it; an art so useful, we might so necessary, that every young person ht to be instructed in it; and as it is also holesome and pleasant exercise, it ought e regularly taught at schools, as well as other athletic exercises.

The art of swimming is so antient, that we e no accounts of its origin in the history of nation; nor are there any nations so bar-ous but that swimming is known and prac-l among them, and that in greater perfec-than among civilized people. It is pro-e, therefore, that the art, though not ab-tely natural, will always be acquired by ple in a savage state from imitating the te animals, most of whom swim naturally. eed so much does this appear to be the case, very expert swimmers have recommended those who wished to learn, to imitate the ions of the frog in moving through the ele-it of water.

he art of swimming depends entirely n keeping the body in a proper balance, this is easily and almost insensibly ac-ed. The great obstacle is the natural ad which people have of being drowned; this it is impossible to overcome by any g but accustoming ourselves to go into water. With regard to the real danger of g drowned, it is but little; and on innu-able occasions arises entirely from the ter-above mentioned, as will appear from the wing observations by Dr. Franklin:

1st, That though the legs, arms, and head, human body, being solid parts, are spe-ally somewhat heavier than fresh water, the trunk, particularly the upper part, its hollowness, is so much lighter than er, that the whole of the body, taken to-her, is too light to sink wholly under water, some part will remain above until the lungs ome filled with water; which happens from ving water into them instead of air, when rson in the fright attempts breathing while mouth and nostrils are under water.

2dly, That the legs and arms are speci-lly lighter than salt water, and will be sup-ed by it; so that a human body would sink in salt water though the lungs were d as above, but from the greater specific vity of the head.

dly, That therefore a person throwing him-on his back in salt water, and extending arms, may easily lie so as to keep his mouth nostrils free for breathing; and by a small ion of his hands may prevent turning, if he ld perceive any tendency to it.

4thly, That in fresh water, if any man ws himself on his back near the surface, cannot long continue in that situation, but proper action of his hands on the water. e uses no such action, the legs and lower of the body will gradually sink till he comes into an upright position; in which he will continue suspended, the hollow of the breast keeping the head uppermost.

"5thly, But if in this erect position the head is kept upright above the shoulders, as when we stand on the ground, the immersion will, by the weight of that part of the head that is out of the water, reach above the mouth and nostrils, perhaps a little above the eyes; so that a man cannot long remain sus-pended in water with its head in that posi-tion.

"6thly, The body continued suspended as before, and upright, if the head is leaned quite back, so that the face looks upwards, all the back part of the head being then under water, and its weight consequently in a great mea-sure supported by it, the face will remain above water quite free for breathing, will rise an inch higher every inspiration, and sink as much every expiration, but never so low that the water may come over the mouth

"7thly, If therefore a person unacquainted with swimming, and falling accidentally into water, could have presence of mind sufficient to avoid struggling and plunging, and to let the body take this natural position, he might continue long safe from drowning, till per-haps help would come; for as to the clothes, their additional weight while immersed is very inconsiderable, the water supporting it; though when he comes out of the water, he would find them very heavy indeed."

The method of learning to swim is as fol-lows: The person must walk into water so deep that it will reach to the breast. He is then to lie down gently on the belly, keep-ing the head and neck perfectly upright, the breast advancing forward, the thorax inflated, and the back bent; then withdrawing the legs from the bottom, and stretching them out, strike the arms forwards in unison with the legs. Swimming on the back is somewhat similar to that on the belly, but with this dif-ference; that the legs are here chiefly em-ployed to move the body forwards, and the arms are often unemployed, for the progres-sive motion is derived from the movement of the legs. In diving, after the plunge, a per-son uses the same action as in swimming, only the head is bent downwards; and whenever he chooses to return to his former situation, he has nothing to do but bend back his head, and he will immediately return to the sur-face.

It is very common for novices in the art of swimming to make use of corks or bladders to assist in keeping the body above water. Some have utterly condemned the use of these; Dr. Franklin, however, allows that they may be of service for supporting the body while one is learning what is called the stroke, or that manner of drawing in and striking out the hands and feet that is necessary to pro-duce progressive motion. "But (says he) you will be no swimmer till you can place con-fidence in the power of the water to support you: I would therefore advise the acquiring of that confidence in the first place, especially as I have known several who by a little of the practice necessary for that purpose, have insen-sibly acquired the stroke, taught in a manner by nature.

"The practice I mean is this: choosing a place where the water deepens gradually, walk coolly into it till it is up to your breast: then turn round your face to the shore, and throw an egg into the water, between you and the shore; it will sink to the bottom, and be easily seen there if the water is clear. It must lie in the water so deep that you can-not reach it to take it up but by diving for it. To encourage yourself in order to do this, reflect that your progress will be from deeper to shallower water; and that at any time you may, by bringing your legs under you, and standing on the bottom, raise your head far above the water: then plunge under it with your eyes open, throwing yourself towards the egg, and endeavouring, by the action of your hands and feet against the water, to get forward till within reach of it. In this attempt you will find that the water buoys you up against your inclination; that it is not so easy a thing to sink as you imagined; that you cannot but by active force get down to the egg. Thus you feel the power of the water to sup-port you, and learn to confide in that power; while your endeavours to overcome it, and to reach the egg, teach you the manner of act-ing on the water with your feet and hands; which action is afterwards used in swimming to support your head higher above water, or to go forward through it."

SWINE-STONE, in mineralogy. The texture of this substance is often earthy; frac-ture splintery; specific gravity 2.7.; colour grey, of various shades. When scraped or pounded, it emits an urinous or garlic smell.

SWORD, a weapon used either in cut-ting or thrusting; the usual weapon of fights hand to hand. It also signifies, figuratively, destruction by war; as fire and sword.

SWORD, *broad*. An original weapon of Scotland: it is sometimes called a back sword, as having but one edge: it is basket-handled, and three feet two inches long.

SWORD, *regulation*. The sword which is worn by British officers may be properly called a long cut-and-thrust. It is a manifest imita-tion of the Austrian sword, and has been lately introduced. It is not, however, so conveniently used by us as it is by the Aus-trians. The latter have it girted round their waists, so that it hangs without any embarrass-ment to the wearer close to the left hip or thigh; whereas with us, it is suspended in an aukward diagonal manner from a cross belt over the loins.

SWORD, *position of, at open order*. When an officer stands or marches in front of his company, &c. the position of the sword is di-agonal across the chest. At close order, or when the officer is on the flank of his com-pany, &c. the hilt is close to the right thigh, and the blade in the hollow of the right shoul-der. When mounted, he carries it diagonally across the bridle-hand.

When troops or squadrons of cavalry ad-vance, in the walk, the sword is carried with the blade resting on the right arm; in the trot and gallop, the right hand must be stea-died on the right thigh, the point of the sword rather inclining forward; and in the charge, the hand is lifted, and the sword is carried ra-ther forward, and crossways in front of the head, with the edge outwards.

SYENA, a genus of the class and order triandria monogynia. The calyx is three-leaved; petals three; anthers oblong; cap-sules one-celled, three-valved. There is one species, a mossy plant of Guiana.

SYLLOGISM, συλλογισμος, in logic, an argument or term of reasoning, consisting of three propositions; the two first of which are called premises, and the last the conclusion. See Logic, Mode, &c.

SYMPHONIA, a genus of plants of the class of monadelphia, and order of pentandria. There is one pistil. The corolla is globular, and the berry five-celled. There is only one species yet discovered; the globulifera, a tree of Surinam.

SYMPHONY, in music, properly denotes a consonance or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also harmony.

SYMPHYSIS, in anatomy, one of the kinds of junctures of articulation of the bones. See Anatomy.

SYMPHYTUM, *comfrey*, a genus of plants of the class of pentandria, and order of monogynia; and in the natural system ranging under the 41st order, asperifoliæ. The limb of the corolla is tubular and ventricose, and the throat is shut with awl-shaped rays. There are three species; the officinale, tuberosum, and orientale. The officinale is a British plant. The stem is about two feet high, round, branched, green, and rough. The radical leaves are very large and rough; those on the stalk are decurrent, and alternate. The flowers grow on loose spikes, and are either of a yellowish or purple colour. It grows on the banks of rivers, and flowers from May to October.

SYMPLOCOS, a genus of plants of the class of polyadelphia, and the order of polyandria; and in the natural system ranging under those the order of which has not been determined. The calyx is quinquefid and inferior: the corolla is pentapetalous: the stamina are attached to the tube of the corolla in a fourfold series. Only one species, the martinicensis, is mentioned by Linnæus; but l'Heritier of the academy of sciences at Paris has added three more, the ciponima, arechea, and octopetala, all trees of the West Indies.

SYNCOPE, *fainting*. See Medicine.

Syncope, in grammar, an elision or retrenchment of a letter or syllable out of the middle of a word, as *caldus* for *calidus*, *aspris* for *asperis*, &c.

SYNGENESIA. See Botany.

SYNGNATHUS, pipefish, a genus of fishes of the order nantes: the generic character is, snout subcylindric, with terminal mouth; body lengthened, jointed, mailed; ventral fins none.

1. Syngnathus acus, great pipefish. The fishes of the present genus are inhabitants of the sea, and are observed to frequent the shallower parts near the shore, feeding on the smaller worms and insects: they are easily distinguished by their slender habit, and angular jointed body. The syngnathus acus or great pipefish is usually seen of the length of twelve or fifteen inches, but is sometimes found, especially in the northern seas, of far greater extent, measuring from two to three feet: it is of an extremely slender form, gradually tapering towards the extremity, and is of a pale yellowish-brown colour, varied throughout its whole length with broad alternate zones of a deeper or olive brown, with a few smaller variegations intermixed: the shields or laminæ with which the joints of the body are covered, appear, if narrowly inspected, to be finely radiated from the centre by numerous lines or streaks: the dorsal fin is placed rather nearer the head than the tail, and is thin, tender, shallow, and of no great extent; the pectoral fins small, and slightly rounded, and the tail of similar shape and size. In spring, as in others of this genus, the ova are found lying in a longitudinal channel or division at the lower part of the abdomen, and are large in proportion to the size of the animal: from these are hatched the young, completely formed. Native of the European seas.

2. Syngnathus hippocampus, sea-horse pipefish. A fish of a highly singular appearance: general length from six to ten inches: body much compressed; colour greenish brown, varied with darker and lighter specks: head large, thickish, and beset on the upper part, as well as along some of the first joints of the body, with several small, weak, lengthened spines or cirrhi, which are sometimes slightly ramified: snout slender: neck contracting suddenly beyond the head: body rather short, and contracting suddenly towards the tail, which is long, quadrangular, and terminates in a naked or finless tip. In its dry or contracted state this animal exhibits the fancied resemblance from which it takes its name, but in the living fish this appearance is somewhat less striking, the head and tail being carried nearly straight. It is a native of the Mediterranean, Northern, and Atlantic seas. See Plate Nat. Hist. fig. 387.

3. Syngnathus foliatus, foliated pipefish. A most extraordinary species; far exceeding all the rest of the genus in the singularity of its appearance, which is such as at first view rather to suggest the idea of some production of fancy than of any real existence. In its general shape it is greatly allied to the preceding species, but is considerably longer in proportion, or of a more slender habit: these appendages are situated on very strong, rough, square spines or processes; and was it not for the perfect regularity of their respective proportions, might be mistaken for the leaves of some kind of fucus adhering to the spines. The colour of the whole animal is a dusky or blackish olive, thickly sprinkled on all parts, except on the appendages, with small round whitish specks, and accompanied by a kind of metallic gloss on the abdomen. There are seven species.

SYNOCHUS, *synocha*. See Medicine.

SYNODENDRON, a genus of insects of the order coleoptera. The generic character is, antennæ clavate; the club lamellate; thorax gibbous, muricate, or unequal; lip filiform; horny palpigerous at the tip. There are four species.

SYNOVIA. See Sinovia.

SYNTAGMA, the disposing or placing of things in an orderly manner.

SYNTAX, in grammar, the proper construction, or due disposition, of the words of a language, into sentences.

SYREN. See Siren.

SYRINGIA, the lilac, a genus of plants of the class of diandria, and order of monogynia; and in the natural system ranging under the 44th order, sepiariæ. The corolla is quadrifid, and the capsule is bilocular. There are three species, the vulgaris, persica, and suspensa. The two first are natives of Persia, and the last of Japan. The vulgaris, which is distinguish[ed] by ovate heart-shaped leaves, was cultivat[ed] in Britain about the year 1597 by Mr. Jo[hn] Gerard. The persica, which has lanceola[te] leaves, was cultivated in 1658; but how lo[ng] both species might have been introduced in Britain before these dates, it is perhaps impo[s]sible to ascertain.

SYRINGE, an instrument serving to i[m]bibe a quantity of any fluid, and to squirt [or] expel the same with violence. See Su[r]gery.

The syringe is made of a hollow cylind[er] ABCD, Plate Miscel. fig. 224, furnished wit[h a] little tube at the bottom, EF. In this cylind[er] is an embolus or piston K, made, or at lea[st] covered, with leather, or some other matt[er] that easily imbibes moisture, and so filli[ng] the cavity of the cylinder, as that no air [or] water may pass between the one and t[he] other. If then the little end of the tube is put into water, and the embolus drawn u[p] the water will ascend into the cavity left [by] the embolus; and upon thrusting back t[he] embolus, it will be violently expelled ag[ain] through the tube EF.

This ascent of the water, the antients, wh[o] supposed a plenum, attributed to nature[’s] abhorrence of a vacuum; but the modern[s] from repeated experiments, have found it [to] be owing to the pressure of the atmosphe[re] upon the fluid; for by drawing up the e[m]bolus, the air left in the cavity of the cyli[n]der will be exceedingly rarified, so th[at] being no longer a counterbalance to the [air] incumbent on the surface of the fluid, th[is] prevails and forces the water through t[he] little tube into the body of the syringe. S[ee] Pneumatics, &c.

SYRINGOTON, the name of an instr[u]ment to lay open the fistula.

SYRUP. See Pharmacy, and Sugar.

SYSTEM, in music, an interval compoun[d]ed, or supposed to be compounded, of seve[ral] lesser intervals, as the fourth, the fifth, t[he] sixth, the octave, &c. the components [of] which, considered as the elements of the s[ys]tem, are called diastems. A system is a[lso] a method of calculation to determine the [re]lations of sounds, or an order of signs [es]tablished to express them: and lastly, a s[ys]tem is the code of harmonic rules dra[wn] from those common principles by which th[ey] are computed.

There is an infinity of different interva[ls] and consequently an infinity also of possi[ble] systems. Any interval between the terms [of] which one or more sounds intervened, [was] by the antients called a system: E, G, [for] example, constituted the system of a mi[nor] third; E, A, of a fourth; E, B, of a fif[th], &c.

Systems were divided into general and p[ar]ticular. The particular systems were th[ose] which were composed of at least two int[er]vals. The general systems, or diagra[ms,] were formed of the sum of all the particu[lar] systems, and consequently contained all [the] sounds in music.

The whole system of the Greeks was o[ri]ginally composed only of four sounds [at] most, which formed the concord of their ly[re] or cithara. These four sounds, according [to] some authors, were by conjoint degrees: [ac]cording to others, they were not diatoni[c;] but the two extremes were at the distance [of] an octave, and the two intermediate ones ed it into a fourth on each side, and a tone he middle. This system did not, howr, continue long confined to so few nds. Chorebus, son of Athis, king of dia, as Boetius informs us, added a fifth rd; Hyagnis a sixth; Serpander a seventh, equal the number of the planets; and chaon an eighth. But Pliny gives a different account of the progression of the annt system: according to that writer, Terider added three chords to the tetrachord, l was the first who used the cithara with en chords; Simonides joined to it an eighth, l Timotheus a ninth.

Whichever of these accounts may be the true one, it seems pretty certain that the system of the Greeks was gradually extended, both upward and downward; and that it attained and even exceeded the limits of the bis-diapason, or double octave, an extent which they called systema perfectum, maximum, immestatum, the great system, the perfect system.

This entire system was composed of four tetrachords, three conjoint and one disjoint, and the chord called proslambanomenos, which was added below these tetrachords to complete the double octave.

This general system of the Greeks remained nearly in this state till the eleventh century, when Guido made a considerable change, by adding a new chord below, which he called hypoproslambanomenos; also a fifth tetrachord above, or tetrachord of the sur-sharp; and substituting hexachords in the place of the antient tetrachords. Since the time of Guido, the general system has again been greatly extended, and divided into octaves; which has long been adopted throughout Europe, and which the ear certainly recognises as the most natural of all possible partitions of the great scale of sounds.

SYSTOLE. See ANATOMY.

SYZYGY. See ASTRONOMY.

T.

T the nineteenth letter of our alphabet.

In abbreviations, amongst the Roman writs, T. stands for Titus, Titius, &c. Tab. for abularius; Tab. P. H. C. Tabularius proncis Hispaniæ citerioris; Tar. Tarquinius; i. Tiberius; Ti. F. Tiberii filius; Ti. L. iberii libertus; Ti. N. Tiberii Nepos; T. A. V. P. V. D. tempora judicem arbiumve postulat ut det; T. M. P. terminum osuit; T M. D D. terminum dedicavit; r. trans, tribunus; Tr. M. or Mil. tribunus ilitum; T R. P L. D E S. tribunus plebis esignatus; T R. A E R. tribunus ærarii; R V. C AP. triumviri capitales; T. R. r TRIB. POT. tribunicia potestata; Tul. I. Tullus Hostilius.

Amongst the antients, T. as a numeral, ood for one hundred and sixty: and with a ash at top, thus T̄, it signified one hundred nd sixty thousand. In music, T stands for utti, all, or altogether.

TABANUS, a genus of insects of the order diptera. The generic character is, mouth ormed into a fleshy proboscis, terminated by wo lips; rostrum furnished with two pointed alpi, placed on each side of, and parallel o, the proboscis. There are 53 species.

The largest of the British species is the tabanus bovinus of Linnæus, having the appearance of a very large grey or pale-brown ly, often measuring near an inch in length, and marked down the back by a series of arge, whitish, triangular spots, pointing downwards; on each side also is an approach also to a similar appearance, though less distinct than that of the dorsal row. This insect, like the rest of the genus, is seen during the middle and the decline of summer; generally in the hottest part of the day. It is extremely troublesome to cattle, piercing their skin with the lancets of its trunk, and sucking its blood in such a manner as to cause considerable pain. It proceeds from a large dusky-yellowish larva, nearly resembling that of a tipula, and marked by transverse blackish streaks or rings; it resides under ground in moist meadows, &c. and changes to a cylindric brownish chrysalis, with a roundish or very slightly pointed extremity; out of which, in the space of a month, proceeds the perfect insect. See Plate Nat. Hist. fig. 388.

2. Tabanus tropicus is of a smaller size than the preceding, and of a brown colour, with the sides of the abdomen bright ferruginous. It is a less common species than the former.

3. Tabanus pluvialis is of the size of a window-fly, but of a somewhat longer shape in proportion; it is of a dull brown colour, with the wings of a similar cast, but marbled or variegated with very numerous whitish specks: this is a very troublesome insect during the latter part of summer, fastening on the legs, hands, &c. and causing considerable pain by the puncture of its proboscis: it is observed to be peculiarly teasing on the approach of rain.

4. Tabanus cæcutiens is an insect of singular beauty. It is of the size of a common window-fly, and of a yellowish-brown colour varied with back; the wings are transparent, and marked by large black bands or patches, and the eyes are of the most vivid or lucid green, marbled with black spots and streaks. It is by no means uncommon during the autumnal season.

TABBY, in commerce, a kind of rich silk, which has undergone the operation of tabbying. See the next article.

TABBYING, the passing a silk or stuff through a calender, the rolls of which are made of iron or copper, variously engraven; which bearing unequally on the stuff, renders the surface unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABELLA, TABLET. See PHARMACY.

TABERNÆMONTANA, a genus of plants of the class of pentandria, and order of monogynia; and in the natural system arranged under the 30th order, contortæ. There are two horizontal folioles, and the seeds are immersed in pulp. There are 19 species, all of foreign growth.

TABES DORSALIS. See MEDICINE.

TABLE, in perspective, denotes a plane surface, supposed to be transparent, and perpendicular to the horizon. It is always imagined to be placed at a certain distance between the eye and the objects, for the objects to be represented thereon by means of the visual rays passing from every point thereof through the table to the eye; whence it is called perspective-plane.

TABLES, *laws of the twelve*, were the first laws of the Romans; thus called either because the Romans then wrote with a style on thin wooden tablets covered with wax, or rather, because they were engraven on tables, or plates of copper, to be exposed in the most noted part of the public forum. After the expulsion of the kings, as the Romans were then without any fixed or certain system of law, at least had none ample enough to comprehend the various cases that might fall between particular persons, it was resolved to adopt the best and wisest laws of the Greeks. One Hermodorus was first appointed to translate them, and the decemviri afterwards compiled and reduced them into ten tables. After much care and application, they were at length enacted and confirmed by the senate and an assembly of the people, in the year of Rome 303. The following year they found something wanting in them, which they supplied from the laws of the former kings of Rome, and from certain customs which long use had authorised; all these being engraven on two other tables made the law of the twelve tables, so famous in the Roman jurisprudence, the source and foundation of the civil or Roman law.

TABLE, among the jewellers. A table-diamond, or other precious stone, is that whose upper surface is quite flat, and only the sides cut in angles; in which sense a diamond cut tablewise, is used in opposition to a rose-diamond.

TABLE, in mathematics, systems of numbers calculated to be ready at hand for the expediting astronomical, geometrical, and other operations: thus we say tables of the stars; tables of sines, tangents, and secants; tables of logarithms, rhumbs, &c. sexagenary tables.

TACAMAHACA. See POPULUS, and RESINS.

TACCA, a genus of the class and order hexandria monogynia. The cal. is six-parted; cor. six-petalled, inserted into the cal.; stigma stellate; berry dry, hexangular, &c. There is one species, a herb of the East Indies.

TACHYGRAPHY, the art of writing fast or of short hand; of which authors have invented several methods. See STENOGRAPHY.

TACK, in a ship, a great rope having a wale-knot at one end, which is seized or fastened into the clew of the sail; so is reefed first through the chess-trees, and then is brought through a hole in the ship's side. Its use is to carry forward the clew of the sail, and to make it stand close by a wind: and whenever the sails are thus trimmed, the main-tack, the fore-tack, and mizen-tack, are brought close by the board, and haled as much forward on as they can be.

TACK-ABOUT, in the sea-language, is to turn the ship about, or bring her head about, so as to lie the contrary way.

TACKLE, or TACKLING, among seamen, denotes all the ropes or cordage of a ship, used in managing the sails, &c. In a more restrained sense, tackles are small ropes running in three parts, having at one end a pendant and a block; and at the other end a block and a hook, to hang goods upon that are to be heaved into the ship or out of it.

TACTICS, in the art of war, is the method of disposing forces to the best advantage in order of battle, and of performing the several military motions and evolutions. See WAR, *art of*.

TACTICS, in the military art, a word derived from the Greek, signifying order. Tactics consist of a knowledge of order, disposition, and formation, according to the exigency of circumstances in warlike operations.

General tactics are a combination or union of first orders, out of which others grow of a more extensive and complicated nature, to suit the particular kind of contest or battle which is to be given, or supported. Let it not, however, be inferred from this, that evolutions and tactics are one and the same. They are closely connected, but there is still a discernible difference between them.

Tactics may be comprehended under order and disposition; evolution is the movement which is made, and eventually leads to order. The higher branches of tactics should be thoroughly understood by all general officers; but it is sufficient for inferior officers and soldiers to be acquainted with evolutions. Not that the latter are beneath the notice of general officers; but that having already acquired a knowledge of them, they ought to direct their attention more immediately to the former, carefully retaining at the same time a clear apprehension of every species of military detail, and consequently obviating the many inconveniences and embarrassments which occur from orders being awkwardly expressed by the general, and of course ill understood by the inferior officer. It may be laid down as a certain rule, that unless a general officer makes himself acquainted with particular movements and dispositions, and preserves the necessary recollections, it is morally impossible for him to be clear and correct in his general arrangements. Of all mechanical operations, founded upon given principles, the art of war is certainly the most compendious, the most enlarged, and the most capable of improvement. Almost every other science and art are comprehended in it; and it should be the subject matter, the chief study, and the ultimate object, of a general's reflections. He must not be satisfied with a limited conception of its various branches; he should go deeply into all its parts, be aware of its manifold changes, and know how to adapt movements and positions to circumstances and places.

It will be of little use to a general to have formed vast projects, if, when they are to be executed, there should be a deficiency of ground; if the general movements of the army should be embarrassed by the irregularity of some particular corps, by their overlapping each other, &c.; and if, through the tardiness of a manœuvre, an enemy should have time to render his plan abortive by a more prompt evolution. A good general must be aware of all these contingencies, by making himself thoroughly master of tactics.

The Prussian tactics under Frederic the Great, had for their principal object to concentrate forces, and to attack the chief points of an enemy, not at one and the same time, but one after another: whereas the tactics which have been uniformly pursued by the French, since the commencement of their revolution, have been founded upon this principle; to attack all points with divided forces, at one and the same time. We thus see, that the principles of extension have been as much followed by the latter, as those of compression were studiously adhered to by the former.

Tactics of Europe. The following observations respecting the tactics of Europe, which we extract from a book entitled the Elementary Principles of Tactics, page 137, may not be uninteresting to our military readers:

In the time of the Romans, the Gauls and other nations on the continent fought in the phalanx order; it is this order which still prevails through all Europe, except that it is deficient in the advantages and utility which Polybius ascribes to it, and is injured and disgraced by defects unknown to the antient phalanx.

In Turenne's days, troops were ranged 8 deep, both in France and Germany. Thirty years after, in the time of Puysegur, the ranks were reduced to 5; in the last Flanders war to 4; and immediately after to 3; at present the ranks are reduced to 2.

This part of the progression from eight to three being known, we easily conceive how the files of the phalanx have been diminished from sixteen to eight in the ages preceding Turenne. It is to be presumed, that this depth was considered as superfluous; and it was judged necessary to curtail it, in order to extend the front. However, the motion is of very little consequence, since we are now reduced to three ranks; let us therefore endeavour to find out what qualities of the phalanx have been preserved, and what might have been added to it.

To shew that we have preserved the defects of the phalanx in Europe, we suppose two bodies of troops, one of eight thousand men, ranged as a phalanx, sixteen deep; the other a regiment of three battalions, consisting only of fifteen hundred men, drawn up in three lines after the same manner. These two bodies shall be perfectly equal and alike in extent of front, and shall differ in nothing but in the depth of their files; the inconveniences and defects, therefore, occasioned by the length of their fronts, are equal in both troops, though their numbers are very different; hence it follows, that in Europe, the essential defects of the phalanx are preserved, and its advantages lost.

Let the files of this body of eight thousand be afterwards divided, and let it be reduced to three in depth, its front will then be found five times more extensive, and its depth five times less; we may therefore conclude, that the defects of the phalanx are evidently multiplied in the discipline of Europe, at the expence of its advantages, which consisted in the depth of its files.

The progress which has taken place in the artillery, has contributed greatly to this revolution. As cannon multiplied, it was necessary to avoid its effects; and the only method of avoiding, or at least of lessening them, was doubtless to diminish the depth of the files.

The musquet, likewise, has a great share in the alteration; the half-pike was entirely laid aside for the bayonet; and in order to have no fire unemployed, it was thought necessary to put it in the power of every soldier to make use of his.

These are the two principal causes of the little solidity or depth given to our battalions.

We have now seen, that the defects of the phalanx were multiplied in the European discipline, and its advantages and perfection infinitely diminished. Our regulations are therefore, much inferior to the phalanx, and have nothing but the single effect of fire-arms to counterbalance all its advantages. The effect, however, of fire-arms, is an artificial power, and does not originally belong to the manner of disciplining troops, the sole aim of which should be to employ man's natural action. It is man, therefore, and not this fire, which is to be considered as the principal agent; and hence we may infer that this method is very much inferior to the phalanx, and still more to the Roman arrangement, which so far surpassed that of Greece.

The light troops of both these people were much heavier than our battalions, and had more power and solidity for a shock or conflict. However, the Roman discipline, notwithstanding its superiority, is not calculated for our times; because, as we are obliged to engage at a distance, ours, by its cannon, would destroy the Grecian order of battle in a very short time, and would be exposed to a loss much less considerable itself, supposing even the artillery was equal on both sides; we should then, in order to perfect our arrangements, endeavour to procure them all the advantageous qualities of the legionary regulations, as the only means of giving them the superiority.

Many people are of opinion, that we imitate the Romans, and that we give battle according to their system, because our troops are drawn up in lines, some of which are full, and others vacant. But it has been proved, that three battalions have the same front, and the same inconveniences, that eight thousand men, ranged in the phalanx order. Our lines are formed by brigades, regiments, or battalions, and the distance of one corps to the other is equal to the front of one of those corps: so that those lines, both full and vacant, are composed of detachments equal in front and in defects; each has a phalanx of six, eight, or twelve thousand men. Our orders of battle, consequently, can be no more at most than a kind of medium between those of Greece and Rome.

TACTICS, *maritime*, or manœuvres at sea. With respect to naval tactics, or the art of fighting at sea, it is confessedly less antient than tactics on shore, or what is generally called land-service. Mankind were accustomed to contend for the possession of territory long before they determined on, or even dreamed of, making the sea a theatre of war and bloodshed.

Setting aside the many fabulous accounts which are extant concerning naval tactics, we shall remain satisfied with what has been transmitted to us by the Roman writers of the fifth and sixth centuries of that republic. We shall there find specific details of the different manœuvres which were practised at sea during the Punic war. In those times naval armaments began to be regularly fitted out; ships of different forms and sizes were constructed; and certain offensive and defensive machines, that served as a species of artillery, were placed upon them. They had already been drawn out according to system; being divided into certain proportions which were then called divisions, but are now named squadrons; and the persons who commanded them, exerted all their skill and genius to gain advantages over their enemies, by opportunely getting to windward, by seizing the favourable occurrence of the tide, or by mooring in advantageous situations.

At the battle of Actium, Augustus, finding himself inferior to Mark Anthony in the number of his ships, had the sagacity to draw up his line of battle along the entrance of the gulph of Ambracia, and thereby to make up for his deficiency. This naval manœuvre, as well as that of getting to windward of the enemy, in order to bear down upon him with more certainty and effect, exists to the present day.

We act precisely upon the same principles in both cases, by which the antients were governed; with the additional advantage, in fighting to windward, of covering the enemy's line with smoke from the discharge of ordnance and fire-arms. The French call this being in possession of the closest line.

In those times, ships were boarded much sooner than they are at present. Most engagements at sea are now determined by cannon-shot. Among the antients, when two ships endeavoured to board each other, the rowers drew in their oars, to prevent them from being broken in the shock.

The manœuvre which was practised on this occasion, was for the ship that got to windward of its adversary, to run upon its side, with the prow; which being armed with a long sharp piece of iron, made so deep an impression in it, that the ship thus attacked, generally sunk. The voyages which were afterwards made on the ocean, rendered it necessary to construct ships that carried more sail, and were double-decked; and since the invention of gunpowder, tiers of guns have been substituted in the room of rows of oars.

On the decline and fall of the Roman empire, the Saracens got the ascendancy in naval tactics. They took advantage of this superiority, and extended their conquests on all sides. The whole extent of coast belonging to the Mediterranean, together with the adjacent islands, fell under their dominion. Mankind are indebted to them for considerable improvements in naval tactics.

It was only under Charlemagne, that the Europeans can be said to have paid any great attention to their navy. That monarch kept up a regular intercourse with the caliphs of the East; and having just grounds to apprehend an invasion from the Normans, he constructed vessels for the defence of his coasts.

During the reign of the first French kings belonging to the third race, naval tactics were little attended to, on account of the small extent of maritime coast which France possessed at that period. It was only in the days of Louis the Younger, and of Louis surnamed the Saint, that we discover any traces of a considerable fleet, especially during the crusades.

Under Charles the Fifth, and his successor Charles the Sixth, the French got possession of several sea-ports, and had command of a long line of coast. Yet neither they nor the English, with whom they were frequently at war, had at that period any thing like the fleets which are now fitted out.

The discovery of America by Columbus, and the more lucrative possession of the East Indies, induced the principal states of Europe to increase their naval establishments, for the purpose of settling colonies, and of bringing home, without the danger of molestation or piracy, the wealth and produce of the eastern and western worlds.

The French marine was far from being contemptible under Francis the First; but it grew into considerable reputation during the administration of cardinal Richelieu, in the reign of Louis the Thirteenth; and continued so until the battle of La Hogue, which was so gloriously won by the English, under William the Third. From that epoch it began to decline; while the English, on the other hand, not only kept up the reputation they had acquired under Cromwell and his predecessors, but rendered themselves so thoroughly skilled in naval tactics, that they have remained masters of the sea to this day. See WAR, *art of*.

TÆNIA, the TAPE-WORM, in zoology, a genus of animals belonging to the class of vermes, and order of intestina. The body is long, depressed, and jointed like a chain, and contains a mouth and viscera in each joint. According to Gmelin, there are ninety-two species; all which inhabit the intestines of various animals, particularly of quadrupeds.

Seven species of tænia are peculiar to man: 1. The visceralis, which is inclosed in a vesicle, broad in the fore part, and pointed in the hinder part; inhabits the liver, the placenta uterina, and the sac which contains the superfluous fluid of dropsical persons. 2. Cellulosa, which is inclosed in a cartilaginous vesicle, inhabiting the cellular substance of the muscles; is about an inch long, half an inch broad, and one-fourth of an inch thick, and is very tenacious of life. 3. The dentata, has a pointed head; the large joints are streaked transversely, and the small joints are all dilated; the osculum or opening in the middle of both margins is somewhat raised. It is narrow, ten or twelve feet long, and broad in the fore parts; its ovaria are not visible to the naked eye; and the head underneath resembles a heart in shape. It inhabits the intestines. 4. The lata, is white, with joints very short and knotty in the middle; the osculum is solitary. It is from eighteen to one hundred and twenty feet long; its joints are streaked transversely; its ovaria are disposed like the petals of a rose. 5. The vulgaris, has two lateral mouths in each joint; it attaches itself so firmly to the intestines, that it can scarcely be removed by the most violent medicines; it is slender, and has the appearance of being membranaceous; it is somewhat pellucid, from ten to sixteen feet long, and about four lines and a half broad at one end. 6. The truttæ, which chiefly inhabits the liver of the trout, but is also to be found in the intestines of the human species. 7. The solium, has a marginal mouth, one on each joint. 8. The ovilla, found in the liver and omentum of sheep. See Plate Nat. Hist. fig. 389.

The structure and physiology of the tænia are curious, and it may be amusing as well as instructive to consider it with attention. The tænia appears destined to feed upon such juices of animals as are already animalized; and is therefore most commonly found in the alimentary canal, and in the upper part, where there is the greatest abundance of chyle; for chyle seems to be the natural food of the tænia. As it is thus supported by food which is already digested, it is destitute of the complicated organs of digestion. As the tænia solium is most frequent in this country, it may be proper to describe it more particularly.

It is from three to thirty feet long, some say sixty feet. It is composed of a head in which are a mouth adapted to drink up fluids, and an apparatus for giving the head a fixed situation. The body is composed of a great number of distinct pieces articulated together, each joint having an organ by which it attaches itself to the neighbouring part of the inner coat of the intestine. The joints nearest the head are always small, and they become gradually enlarged as they are farther removed from it; but towards the tail a few of the last joints again become diminished in size. The extremity of the body is terminated by a small semicircular joint, which has no opening in it.

The head of this animal is composed of the same kind of materials as the other parts of its body; it has a rounded opening at its extremity, which is considered to be its mouth. This opening is continued by a short duct into two canals; these canals pass round every joint of the animal's body, and convey the aliment. Surrounding the opening of the mouth are placed a number of projecting radii, which are of a fibrous texture, whose direction is longitudinal. These radii appear to serve the purpose of tentacula for fixing the orifice of the mouth, as well as that of muscles to expand the cavity of the mouth, from their being inserted along the brim of that opening. After the rounded extremity or head has been narrowed into the neck, the lower part becomes flatted, and has two small tubercles placed upon each flatted side; the tubercles are concave in the middle, and appear destined to serve the purpose of suckers for attaching the head more effectually. The internal structure of the joints composing the body of this animal is partly vascular and partly cellular; the substance itself is white, and somewhat resembles in its texture the coagulated lymph of the human blood. The alimentary canal passes along each side of the animal, sending a cross canal over the bottom of each joint, which connects the two lateral canals together.

Mr. Carlisle injected with a coloured size, by a single push with a small syringe, three feet in length of these canals, in the direction from the mouth downwards. He tried the injection the contrary way, but it seemed to be stopped by valves. The alimentary canal is impervious at the extreme joint, where it terminates without any opening analogous to an anus. Each joint has a vascular joint occupying the middle part, which is composed of a longitudinal canal, from which a great number of lateral canals branch off at right angles. These canals contain a fluid like milk.

The tænia seems to be one of the simplest vascular animals in nature. The way in which it is nourished is singular; the food being taken in by the mouth, passes into the alimentary canal, and is thus made to visit in a general way the different parts of the animal. As it has no excretory ducts, it would appear that the whole of its alimentary fluid is fit for nourishment; the decayed parts probably dissolve into a fluid which transudes through the skin, which is extremely porous.

This animal has nothing resembling a brain or nerves, and seems to have no organs of sense but those of touch. It is most probably propagated by ova, which may easily pass along the circulating vessels of other animals. We cannot otherwise explain the phenomena of worms being found in the eggs of fowls, and in the intestines of a fœtus before birth, except by supposing their ova to have passed through the circulating vessels of the mother, and by this means been conveyed to the fœtus.

The chance of an ovum being placed in a situation where it will be hatched, and the young find convenient subsistence, must be very small; hence the necessity for their being very prolific. If they had the same powers of being prolific which they now have, and their ova were afterwards very readily hatched, then the multiplication of these animals would be immense, and become a nuisance to the other parts of the creation.

Another mode of increase allowed to tænia (if we may call it increase) is by an addition to the number of their joints. If we consider the individual joints as distinct beings, it is so; and when we reflect upon the power of generation given to each joint, it makes this conjecture the more probable. We can hardly suppose that an ovum of a tænia, which at its full growth is thirty feet long, and composed of 400 joints, contained a young tænia composed of this number of pieces; but we have seen young tæniæ not half a foot long, and not possessed of fifty joints, which still were entire worms. We have also many reasons to believe, that when a part of this animal is broken off from the rest, it is capable of forming a head for itself, and becomes an independant being. The simple construction of the head makes its regeneration a much more easy operation than that of the tails and feet of lizards, which are composed of bones and complicated vessels; but this last operation has been proved by the experiments of Spallanzani and many other naturalists.

When intestinal worms produce a diseased state of the animal's body which they inhabit, various remedies are advised for removing them; many of which are ineffectual, and others very injurious by the violence of their operation. Drastic purges seem to operate upon tæniæ, partly by irritating the external surface of their bodies, so as to make them quit their holds, and partly by the violent contractions produced in the intestine, which may sometimes divide the bodies of tænia, and even kill them by bruising. The most effectual remedy, however, has been found to be the digitalis in substance.

TAGETES, *French marigold*, a genus of plants of the class of syngensia, and order of polygamia superflua; and in the natural system ranging under the 49th order, compositæ. The receptacle is naked; the pappus consists of five erect awns or beards; the calyx is monophyllous, quinquedentate, and tubular; and there are four persistent florets of the ray. There are three species, the patula, erecta, and minuta; of which the two first have been cultivated in the British gardens, at least since the year 1596, for it is mentioned in Gerard's Herbal, which was published that year. They are both natives of Mexico.

The erecta, or African marigold, has a stem subdividing and spreading, and has formed itself into a great many varieties: 1. Pale yellow, or brimstone-colour, with single, double, and fistulous flowers. 2. Deep yellow, with single, double, and fistulous flowers. 3. Orange-coloured, with single, double, and fistulous flowers. 4. Middling African, with orange-coloured flowers. 5. Sweet-scented African. These are all very subject to vary; so that unless the seeds are very carefully saved from the finest flowers, they are apt to degenerate; nor should the same seeds be too long sown in the same garden, for the same reason; therefore those who are desirous to have these flowers in perfection, should exchange their seeds with some person of integrity at a distance, where the soil is of a different nature, at least every other year. If this is done, the varieties may be continued in perfection.

TAIL, or ESTATES TAIL, are either general or special. Tail general, is where lands and tenements are given to one and the heirs of his body begotten, which is called tail general; because, how often soever such donee may be married, his heirs, by every such marriage, are capable of inheriting the estate tail. Tenant in tail special, is where the gift is restrained to certain heirs of the grantee, and not to all in general, which may happen several ways. Estates tail are likewise diversified by the distinction of male and female, as if lands are given to a man and the heirs male of his body begotten; this is an estate in tail, male special: but if to a man and the heirs female of the body of his present wife begotten, this is an estate in tail, female special. So in case of a gift in tail male, the female line shall not inherit; and so e converso.

As the word heirs is necessary to create a fee, so the word body or some other words of procreation are necessary to make a fee tail, and ascertain to what heirs the estate is limited. Therefore, if the words of inheritance or procreation are omitted, although the others are inserted, this will not make an estate tail. As if an estate is granted to a man and the issue of his body, this is only an estate for life, the words of inheritance being wanting; and a grant to a man, and his heirs male or female, is an estate in fee simple, not in fee tail, as there are no words to ascertain the body from whence they shall issue. Though in wills, where greater latitude is given, an estate tail may be devised by the words, to a man and his heirs male, or other irregular modes of expression.

The incidents to a tenancy in tail are principally these:

1. A tenant in tail may commit waste on an estate without being impeached for the same.

2. That the wife shall have her dower of the estate tail.

3. That the husband of a female tenant in tail may be tenant by courtesy.

4. An estate tail may be barred or destroyed by a fine, a recovery, or lineal warranty, descending with assets to the heir.

And by stat. 26 Hen. VIII. c. 13. all estates tail (in common with all estates of inheritance) are forfeited to the king on conviction of high treason.

By stat. 32 Hen. VIII. c. 28. certain leases which do not tend to the prejudice of the heir are allowed to bind the issue in tail. A stat. of the same year, c. 36. declares a fine duly levied by a tenant in tail to be a complete bar to all persons claiming under such entail.

And lastly, by 33 Hen. VIII. c. 39. all estates tail are liable to be charged for debts to the king by record or special contract.

They are likewise subject to be sold for the debts contracted by a bankrupt; and by the construction put on stat. 43 Eliz. c. 4. an appointment by tenant in tail, of the lands entailed to a charitable use, is good without fine or recovery.

TAIL, in the Turkish customs, (bashaws of three tails, &c.) See TUG.

TALC. Though this term has often been a synonym of mica in mineralogy, it is adopted by the moderns, to denote a stony substance which differs from it, especially in an unctuosity sensible to the touch, and in the vitreous electricity which it communicates to sealing-wax by friction, whilst mica gives it the resinous electricity. Hauy enumerates four varieties of this stone; namely, the laminary talc, or Venice talc; the foliated talc, or chalk of Briançon; compact talc, as the lard-stone; these three first give the positive or vitreous electricity to sealing-wax. The fourth variety, or the steatites talc, communicates the negative or resinous electricity to it by friction.

The characters of this stone are, a specific gravity between 3.5834 and 2.9902; a texture easy to be scraped with the knife; a soft and unctuous surface; the primitive form of a right rhomboidal prism, its bases having angles of 120 degrees and 60 degrees, and in which sections parallel with these bases are easily obtained. Its integrant molecule has the same form.

Mr. Kirwan has found in this stone almost as much magnesia as silex, and only a twentieth part of alumina. Amongst the varieties of talc, which are sufficiently numerous, the mixed steatites, the serpentine, and pot stones, are not ranked.

The softness of the texture of the talcs, the fineness of their powder, their easy suspension in water (which they powerfully absorb), and the hardness which they contract by the action of a moderate heat, render them useful in a great number of the arts, or for domestic purposes.

A specimen analysed by Mr. Kirwan contained

Silex	5.0
Alumina	5
Magnesia	4.5
	100

TALENT, a money of account amongst the antients, equal to 342*l.* sterling. See Coin, and Money.

Amongst the Jews, a talent in weight was equal to 60 maneh, or 113 pounds, 10 ounces, 1 pennyweight, 10 and two-seventh grains.

TALES, is used in law for a supply of men impanelled on a jury, and not appearing, or on their appearance challenged and disallowed, when the judge upon motion orders a supply to be made by the sheriff of one or more such persons present in court, to make up a full jury.

TALIO, *lex talionis,* a species of punishment in the Mosaic law, whereby an evil is returned similar to that committed against us by another; hence that expression, eye for eye, tooth for tooth. This law was at first inserted in the twelve tables amongst the Romans; but afterwards set aside, and a power given to the prætor to fix upon a sum of money for the damages done.

TALLOW-TREE. See Croton.

TALLY, in law, a piece of wood cut in two parts, whereon accounts were antiently kept, by means of notches; one part of the tally being kept by the debtor, and the other by the creditor. As to the tallies or loans, one part thereof is kept in the exchequer, and the other part given to particular persons in lieu of an obligation for the moneys they have lent to the government on acts of parliament. This last part is called the stock, and the former the counter-stock, or counter-tail.

TALMUD, or Thalmud, among the Jews, a collection of the doctrines of their religion or morality. It is the corpus juris, or body of the laws and customs of the Jews, who esteem it equal to the scriptures themselves.

TALPA, mole, a genus of the quadrupeds of the order feræ. The generic character is, front teeth in the upper jaw six, unequal; in the lower jaw eight; canine teeth one on each side, the upper ones largest; grinders seven in the upper jaw, six in the lower.

The genus talpa or mole is readily distinguished by its peculiar shape, habit, or general appearance, even without an examination of the teeth; in which particular some species resemble the genus sorex, and were placed in that genus by Linnæus. There are 21 species; the most remarkable are:

1. Talpa Europæa, the common mole. The whole form of the mole is eminently calculated by nature for its obscure and subterraneous life. The body is thick and cylindric; the snout slender, but very strong and tendinous; the head not distinguished from the body by any appearance of neck; the legs so extremely short as scarcely to project perceptibly from the body; the skin is much thicker and tougher in proportion than in other quadrupeds, and the fur with which it is covered equally surpasses that of other animals in fineness and softness. The muscular strength of the mole is very great, and it is enabled to force itself into the ground with an extraordinary degree of celerity. The general length of the mole is about five inches and three quarters, exclusive of the tail, which measures one inch. This animal is supposed to possess the power of hearing in an exquisite degree; and if at any time it emerges from its subterraneous retreat, instantly disappears on the approach of any danger. When first taken, either by digging it out or otherwise, it utters a shrill scream, and prepares for defence by exerting the strength of its claws and teeth. According to the count de Buffon, so lively and reciprocal an attachment subsists between the male and female, that they seem to dread or disrelish all other society.

The mole is furnished with eyes so extremely small that it has been doubted whether they were intended by nature for distinct vision, or rather merely for giving the creature such a degree of notice of the approach of light as might sufficiently warn it of the danger of exposure. Galen, however, seems to have been of a different opinion, since he ventures to affirm that the eyes of the mole are furnished with the crystalline and vitreous humours, encompassed with their respective tunics; so accurate an anatomist was that great man, even unassisted by glasses.

The mole is reported to feed not only on worms, insects, &c. but also on the roots of vegetables; but it is certainly more carnivorus than frugivorous. It is even a very fierce and voracious animal in particular circumstances; and it is observed by sir Thomas Brown, that whatever these animals are contented with under ground, yet, when above it, they will sometimes tear and eat one another; and in a large glass case, wherein a mole, a toad, and a viper, were inclosed, we have known (says he) the mole to dispatch them, and to devour a good part of them both.

The mole is with difficulty kept alive in a state of confinement, unless constantly supplied with a provision of damp mould to reside in.

Like other animals of a black colour, the mole is sometimes found perfectly white, or cream-coloured, and sometimes spotted. In a memoir relative to the mole, published by M. de la Faille, it appears that four varieties may be reckoned, viz. the white mole, the rufous or tawny mole, the greenish-yellow or citron-coloured mole (found in some parts of Languedoc), and, lastly, the spotted mole, which is variegated either with white or tawny spots or patches. The mole brings four or five young.

The greatest misfortune that befals the mole is, the sudden overflowing of rivers, when they are said to be seen swimming in great numbers, and using every effort to obtain a more elevated situation; but a great many of them perish on such occasions, as well as the young, which remain in their holes.

Linnæus, in the twelfth edition of the Systema Naturæ, affirms that the mole hybernates, or passes the winter, in a state of torpidity; and the same observation is repeated in the Gmelinian edition of that work. This, however, is flatly contradicted by the count de Buffon, who observes, that the mole sleeps so little in winter, that she raises the earth in the same manner as in summer; and that the country people remark that the thaw approaches, because the moles make their hills. They endeavour to get into warm grounds, gardens, &c. during this season more than at others.

This animal is said to be unknown in Ireland. In Siberia it arrives at a larger size than in Europe. The fur is so soft and beautiful, that it would make the most elegant articles of dress, did not the difficulty of curing and dressing the skin deter from experiments of this nature.

2. Talpa radiata, radiated mole. This is somewhat smaller than the common mole, and is of a dusky or blackish colour. In general form it resembles the preceding species, having broad fore legs with long claws; the hind legs scaly and with much weaker claws; the nose long, and beset at the end with a circular series of radiated tendrils; the length from nose to tail is three inches and three quarters. It is an inhabitant of North America, forming subterraneous passages, in different directions, in uncultivated fields, and is said to feed on roots. This species is the sorex cristatus of Linnæus; being placed in that genus on account of its teeth, in despite of its appearance. It is, perhaps, in reality, no other than a variety of the former species, or a sexual difference.

TAMARINDUS, the *tamarind-tree,* a genus of plants arranged by Linnæus under the class of triandria and order of monogynia; but Woodville, Schreber, and other late botanists, have found that it belongs to the class of monadelphia, and order of triandria. In the natural system it is ranked under the lomantaceæ. There is only one species, the Indica, which is a native of both Indies, of America, of Arabia, and of Egypt, and was cultivated in Britain before the year 1633.

The tamarind-tree rises to the height of thirty or forty feet, sending off numerous large branches, which spread to a considerable extent, and have a beautiful appearance; the trunk is erect, and covered with rough bark, of a greyish or ash-colour; the leaves are small and pinnated, and of a yellowish green colour; the flowers resemble the papilionaceous kind, and grow in lateral clusters; the calyx consists of four leaves, and the corolla of three petals, which are of a yellowish hue, and are beautifully diversified with red veins; the fruit is a pod of a roundish compressed form, from three to five inches long, containing two, three, or four seeds, lodged in a dark pulpy matter. The tamarind is easily raised with us from the stones even of the preserved fruit, and is a beautiful stove plant, rising to the height of four or five feet.

The pulp of the tamarind, with the seeds connected together by numerous tough strings or fibres, are brought to us freed from the outer shell, and commonly preserved in syrup. According to Long, tamarinds are prepared for exportation at Jamaica in the following manner: "The fruit or pods are gathered (in June, July, and August) when full-ripe, which is known by their easy breaking on small pressure between the finger and thumb. The fruit, taken out of the pod, and cleared from the shelly fragments, is placed in layers in a cask, and boiling syrup, just before it begins to granulate, is poured in till the cask is filled; the syrup prevades every part quite down to the bottom, and when cool the cask is headed for sale." He observes, that the better mode of preserving this fruit is with sugar, well clarified with eggs, till a transparent syrup is formed, which gives the fruit a much pleasanter flavour; but as a principal medicinal purpose of the pulp depends upon its acidity, which is thus counteracted by the admixture of sugar, it would therefore be of more utility if always imported here in the pods. The fruit produced in the East Indies is more esteemed than that of the West, and easily to be distinguished by the greater length of the pods, and the pulp being drier and of a darker colour.

This fruit, the use of which was first learned of the Arabians, contains a larger proportion of acid, with the saccharine matter, than is usually found in the fructus acido-dulcis, and is therefore not only employed as a laxative, but also for abating thirst and heat in various inflammatory complaints, and for correcting putrid disorders, especially those of a bilious kind; in which the cathartic, antiseptic, and refrigerant qualities of the fruit have been found equally useful. When intended merely as a laxative, it may be of advantage to join it with manna, or purgatives of a sweet kind, by which its use is rendered more effectual. Three drachms of the pulp are usually sufficient to open the body; but to prove moderately cathartic, one or two ounces are required. It is an ingredient in electuarium e cassia, and electuarium e senna or lenitive electuary.

TAMARIX, the *tamarisk*, a genus of plants in the class of pentandria, and order of trigynia; and in the natural system ranging under the 13th order, succulentæ. The calyx is quinquepartite; the petals are five; the capsule is unilocular and trivalvular, and the seeds pappous. There are 4 species.

The bark and leaves of the tamarisk-tree are moderately astringent, but never prescribed in the present practice.

TAMBOUR, in fortification, is a kind of work formed of palisades, or pieces of wood, ten feet long and six inches thick, planted close together, and driven two or three feet into the ground; so that when finished it may have the appearance of a square redoubt cut in two. Loop-holes are made six feet from the ground, and three feet asunder, about eight inches long, two inches wide within, and six without. Behind is a scaffold two feet high, for the soldiers to stand upon. They are frequently made in the place of arms of the covert-way, at the salient angles, in the gorges, half-moons, and ravelins, &c.

TAMBOURS, in fortification, are also solid pieces of earth which are made in that part of the covert way that is joined to the parapet, and lies close to the traverses, being only three feet distant from them. They serve to prevent the covert way from being enfiladed, and obstruct the enemy's view towards the traverses When tambours are made in the covert way, they answer the same purposes that works en cremaillére would.

Tambour likewise means in fortification, a single or isolated traverse, which serves to close up that part of the covert way where a communication might have been made in the glacis for the purpose of going to some detached work.

It also signifies, both in French and English, a little box of timber-work covered with a cieling, withinside the porch of certain churches, both to prevent the view of persons passing by, and to keep off the wind, &c. by means of folding-doors. In many instances it is the same as porch.

TAMUS, *black briony*, a genus of plants of the class of diœcia, and order of hexandria, and in the natural system ranging under the 11th order, sarmentaceæ. The male and female flowers are both sexpartite; there is no corolla; the style is trifid; the berry is trilocular and inferior, and contains two seeds. There are only two species. The communis, or common black briony, is a native of England. It has a large root, which sends forth several long slender stems; the leaves are large, heart-shaped, dark green, and grow on long footstalks; the flowers are greenish, and the berry red. It flowers from May to August, and is frequent in hedges.

TAN, the bark of the oak, chopped and ground in a tanning-mill into a coarse powder, to be used in the tanning of leather.

Deyeux was, perhaps, the first chemist who ascertained the peculiar nature of tan, or tanning. He pointed it out in his analysis of nutgalls, as a peculiar resinous substance, but without assigning it any name. Seguin soon after engaged in a set of experiments on the art of tanning leather; during which he discovered that tan has the property of precipitating glue from its solutions in water, and of combining with the skins of animals. This led him to suppose it the essential constituent of the liquids employed for the purpose of tanning leather. Hence the names tannin and tanning principle given it by the French chemists. But it is to Mr. Proust that we are indebted for the investigation of the nature and properties of tan, and of the methods of obtaining it in a separate state. Much curious and important information has likewise been obtained by the experiments of Mr. Davy on the constituent parts of astringent vegetables, and on their operation in tanning.

Tan exists in a great number of vegetable substances; but it may be procured most readily and in the greatest purity from nutgalls and catechu.

Nutgalls are excrescences formed on the leaves of the oak by the puncture of an insect which deposits its eggs on them. The best are known by the name of Aleppo galls, imported in large quantities in this country for the use of the dyers, calico-printers, &c. They are hard like wood, round, often nodulated on the surface, of an olive-green colour, and an excessively disagreeable taste. They are in a great measure soluble in water; what remains behind is tasteless, and possesses the properties of the fibre of wood. A very great proportion of water is necessary to carry off every thing soluble. Deyeux found that a French pound of nutgalls required 96 French pints of water, applied in 20 different portions one after the other, and allowed to macerate each a considerable time. This, reduced to our standard, gives us about 150 English pints to a pound troy of nutgalls.

From the analyses of Deyeux and Davy, it follows that the soluble part of nutgalls consists chiefly of five ingredients; namely, tan, extract, mucilage, gallic acid, and gallat of lime. Mr. Davy found that 500 grains of Aleppo galls formed with water a solution which yielded by slow evaporation 185 grains of matter. This matter he found composed of

130	tan
31	gallic acid and extract
12	mucilage and extract
12	lime and saline matter
185.	

So that the tan constitutes rather more than two-thirds of the whole.

According to Mr. Davy, the strongest infusion of galls is of the specific gravity 1.068; and when evaporated at a temperature below 200°, yields a mass composed of $\frac{9}{10}$ tan, and $\frac{1}{10}$ gallic acid and extract. But at a boiling heat most of the gallic acid is dissipated or destroyed, and a portion of the extract is rendered insoluble in water.

Catechu, or terra japonica as it is also called, is a substance obtained by decoction and evaporation from a species of the mimosa which abounds in India. It has a reddish brown colour, and an astringent taste, leaving an impression of sweetness; it is not altered by exposure to the air. There are two varieties of it; one from Bombay, which has the lightest colour, and a specific gravity of 1.39; and one from Bengal, which is of the colour of chocolate; its specific gravity is 1.28. This substance was examined by Davy, and found to consist chiefly of tan combined with a peculiar species of extract.

Tan obtained from the infusion of nutgalls is a brittle substance, of a brown colour. It breaks with a vitreous fracture, and does not attract moisture from the air. Its taste is exceedingly astringent. It is very soluble in water. The solution is of a deep-brown colour, a very astringent and bitter taste, and has the odour which distinguishes a solution of nutgalls. It froths, when agitated, like a solution of soap; but does not feel unctuous. Tan is still more soluble in alcohol than in water. The solution has a deep-brown colour and an astringent taste.

When heated, it blackens, emits carbonic acid gas, and in the open air bursts, leaving always a small portion of lime.

From the experiments of Proust, Davy, and Deyeux, we learn, that it is capable of combining with oxygen; but at the same time it is either decomposed altogether, or its nature completely altered. Thus nitric acid converts it into a yellowish-brown matter soluble in alcohol, and similar in its properties to an extract. Oxymuriatic acid produces similar effects; and Mr. Proust has observed, that the peroxide of tin changes it also into an extract, perhaps by communicating oxygen.

The action of the metals upon tan does not seem to be great; but almost all the metallic oxides have an affinity for it, and are capable of combining with it; the compound is usually nearly insoluble in water. Hence the reason why the infusion of nutgalls precipitates metallic solutions so readily. These compounds have been hitherto in a great measure overlooked by chemists. The following observations contain the facts at present known.

When the peroxide of tin or zinc is boiled in the infusion of galls, it acquires a dull yellow colour, and abstracts all the constituents from the infusion, leaving behind only pure water. The oxides thus combined with tan, &c. are partly soluble in muriatic acid, and the solution indicates the presence of tan and gallic acid. When the peroxide of tin is allowed to act upon the cold infusion, it abstracts all its constituents in a few days. But Mr. Proust affirms, that in that case the gallic acid is mostly destroyed, and a portion of the tan brought to the state of extract.

When the metallic salts are mixed with the infusion of galls, the precipitate consists of the metallic oxide combined with the tan, the extract, and the acid of the infusion; and, according to Davy, it contains also a portion of the acid of the metallic salt.

Tan produces no change upon the solution of sulphat of iron; but when it is mixed with a solution of the oxysulphat of iron, a deep blue coloured precpitate immediately appears, consisting of the tan combined with the oxide. This precipitate, when dried, assumes a black colour. It is decomposed by acids.

When too great a proportion of oxysulphat of iron is poured into a solution of tan, the sulphuric acid, set at liberty by the combination of the iron and tan, is sufficient to re-dissolve the precipitate as it appears; but the precipitate may easily be obtained by cautiously saturating this excess of acid with potass. When the experiment is performed in this manner, all the oxysulphat of iron which remains in the solution undecomposed is converted into sulphat. Mr. Proust supposes that this change is produced by the tan absorbing oxygen from the iron. The same change takes place if oxide is mixed with a considerable excess of sulphuric acid, and diluted with water. Common writing-ink is a combination of gallat of iron and tannat of iron.

The alkalies combine readily with tan, and form with it a compound soluble in water. This was first observed by Deyeux, whose experiments have been verified by Mr. Davy. When potass or soda is added to the infusion of nutgalls, the liquid assumes a reddish-brown colour, and loses the property of precipitating gelatine, till alkali is saturated with an acid. When the alkalized infusion is evaporated to dryness, an olive-coloured mass remains of a faint alkaline taste, which deliquesces in the air. Ammonia produces the same effect upon the infusion of galls; but when the mixture is exposed to the heat of boiling water, part of the ammonia flies off, a precipitate falls, consisting of most of the tan and gallic acid, while the extract remains in solution.

All the earths hitherto tried have a strong affinity for tan, and form with it compounds for the most part insoluble in water, the properties of which have scarcely been examined by chemists.

One of the most important properties of tan is the insoluble compound which it forms with glue or gelatine, as this substance is termed by chemists. It is therefore employed to detect the presence of gelatine in animal fluids: and, on the other hand, solutions of gelatine are employed to detect the presence of tan in vegetable fluids, and to ascertain its quantity. Now, although the compound of gelatine and tan is insoluble in water, it is soluble both in the solution of tan and of gelatine when sufficiently diluted. It is necessary, therefore, that the solution of gelatine, used to detect tan, should be as concentrated as is consistent with its perfect fluidity; for glue, when gelatinous, does not act upon tan. It is necessary also that it should be employed quite fresh; for when in a state of putrefaction, it loses its property of precipitating tan. Mr. Davy has ascertained that the best proportion for use is a solution of 120 grains of isinglass in 20 ounces of water. Care must be taken not to add an excess of the solution to the liquid from which the tan is to be separated; because the compound of tan and gelatine is re-dissolved by the solution of gelatine. According to the analysis of Mr. Davy, this compound, when dried in the temperature of 150°, is composed of

54 gelatine
46 tan

100.

It appears, from the experiments of Mr. Davy and Mr. Chenevix, that tan is sometimes formed in vegetables by the action of heat. Thus no tan can be detected in the decoction of coffee-beans, unless they have been roasted; but in that case their decoction precipitates gelatine.

From the experiments of Mr. Davy, we learn that the affinities of the different classes of bodies capable of combining with tan are nearly in the following order:

Earths,	Acids,
Alkalies,	Neutral salts.
Gelatine,	

But the order of the individual substances belonging to each of these classes remains still to be ascertained.

Tan affects particularly the bark of trees: but it exists also in the sap and in the wood of a considerable number, and even in the leaves of many. It is very seldom that it exudes spontaneously; yet this seems to be the case with a variety of kino.

It has been ascertained by Mr. Biggin, that when the barks of trees are examined at different seasons, they vary in the quantity of tan. The quantity varies also with the age and size of the trees. The greatest proportion of tan is contained in the inner barks. The epidermis usually contains none.

The following table exhibits the proportion of solid matter extracted by water from different vegetable substances, and the quantity of tan contained in that solid matter, as ascertained by the experiments of Mr. Davy.

One Ounce of	Solid Matter. Grains.	Tan. Grains.
White inner bark of old oak	108	72
——— young oak	111	77
——— Spanish chesnut	89	63
——— Leicester willow	117	72
Coloured or middle bark of oak	43	19
——— Spanish chesnut	41	14
——— Leicester willow	34	16
Entire bark of oak	61	29
Entire bark of Spanish chesnut	53	21
——— Leicester willow	71	33
——— elm	—	13
——— common willow	—	11
Sicilian sumach	165	78
Malaga sumach	156	79
Souchong tea	—	48
Green tea	—	41
Bombay catechu	—	261
Bengal catechu	—	231
Nutgalls	180	127

TANACETUM, *tansy*, a genus of plants of the class of syngenesia, and order of polygamia superflua, and in the natural system ranging under the 49th order, compositæ. The receptacle is naked; the pappus somewhat emarginated; the calyx imbricated and hemispherical; the florets of the radius are trifid, and scarcely distinguishable. There are nine species; of which one only is a native of Britain, the vulgare, or common tansy. Of this species there is a variety with curled leaves, which is therefore called curled tansy. The tansy has a bitter taste, and an aromatic smell, disagreeable to many people. It is esteemed good for warming and strengthening the stomach; for which reason the young leaves have obtained a place among the culinary herbs, their juice being an ingredient in puddings, &c. It is rarely used in medicine, though extolled as a good emmenagogue. A drachm of the dried flowers has been found very beneficial in hysteric disorders arising from suppression. The seeds and leaves were formerly in considerable esteem for destroying worms in children, and are reckoned good in cholics and flatulencies.

TANÆCIUM, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 25th order, putamineæ. The calyx is monophyllous, tubulated, truncated, and entire: the corolla long, monopetalous, and white; the tube cylindrical; the lymbi erect, spreading, and nearly equal; the fruit a berry, covered with a thick bark, large, oblong, internally divided into two parts; in the pulp are contained a number of seeds. There are only two species of this genus, the jaroba and parasiticum, both natives of Jamaica. They grow by the sides of rivers, and climb on trees and bushes.

TANAGRA, *tanager*, in ornithology, a genus of birds belonging to the order of passeres. The beak is conical, acuminated, emarginated, almost triangular at the base, and inclining a little towards the point. Dr. Latham has described 44 species, all of which are of foreign extraction. See Plate Nat. Hist. fig. 390.

TANGENT, in geometry, is defined, in general, to be a right line which touches any arch of a curve, in such a manner that no right line can be drawn betwixt the right line and the arch. See Plate Miscel. fig. 226.

The tangent of an arch is a right line drawn perpendicularly from the end of a diameter, passing to one extremity of the arch, and terminated by a right line drawn from the centre through the other end of the arch, and called the secant.

The tangent of a curve is a right line which only touches the curve in one point, but does not cut it.

In order to illustrate the method of drawing tangents to curves, let ACG (fig. 227) be a curve of any kind, and C the given point from whence the tangent is to be drawn. Then conceive a right line, mg, to be carried along uniformly, parallel to itself, from A towards Q; and let, at the same time, a point p so move in that line, as to describe the given curve ACG: also let mm, or Cn, express the fluxion of Am, or the velocity wherewith the line mg is carried; and let nS express the corresponding fluxion of mp, in the position mCg, or the velocity of the point p, in the line mg: moreover, through the point C let the right line SF be drawn, meeting the axis of the curve, AQ, in F.

Now it is evident, if the motion of p, along the line mg, was to become equable at C, the point p would be at S, when the line itself had got into the position mSg; because, by the hypothesis, Cn and nS express the distances that might be described by the two uniform motions in the same time. And if vsg is assumed to represent any other position of that line, and s the contemporary position of the point p, still supposing an equable velocity of p; then the distances Cv, and vs, gone over in the same time by the two motions, will always be to each other as the velocities, or as Cn to nS. Therefore, since Cv : vs :: Cn : nS (which is a known property of similar triangles), the point s will always fall in the right line FCS fig. 228; whence it appears, that if the motion of the point p along the line mg was to become uniform at C, that point would then move in the right line CS, instead of the curve-line CG. Now, seeing the motion of p, in the description of curves, must either be an accelerated or retarded one; let it be first considered as an accelerated one, in which case the arch CG will fall wholly above the right line CD, because the distance of the point p from the axis AQ, at the end of any given time, is greater than it would be if the acceleration was to cease at C; and if the acceleration had ceased at C, the point p would have been always found in the said right line FS. But if the motion of the point p is a retarded one, it will appear, by arguing in the same manner, that the arch CG will fall wholly below the right line CD, as in fig. 228.

This being the case, let the line mg, and the point p, along that line, be now supposed to move back again, towards A and m, in the same manner they proceeded from thence: then, since the velocity of p did before increase, it must now, on the contrary, decrease; and therefore as p, at the end of a given time, after repassing the point C, is not so near to AQ, as it would have been had the velocity continued the same as at C, the arch Cb (as well as CG) must fall wholly above the right line FCD: and by the same method of arguing, the arch Cb, in the second case, will fall wholly below FCD. Therefore FCD, in both cases, is a tangent to the curve at the point C: whence the triangles FmC and CnS being similar, it appears that the sub-tangent mF is always a fourth proportional to nS, the fluxion of the ordinate Cn, the fluxion of the absciss, and Cm the ordinate; that is, Sn : nC :: mC : mF. Hence, if the absciss Am $= x$, and the ordinate $mp = y$, we shall have $mF = \frac{y\dot{x}}{\dot{y}}$; by means of which general expression, and the equation expressing the relation between x and y, the ratio of the fluxions $\dot{x}$ and $\dot{y}$ will be found, and from thence the length of the sub-tangent mF, as in the following examples.

Example I. To draw a right line CT (fig. 229) a tangent to a given circle BCA, in a given point C. Let CS be perpendicular to the diameter AB, and put AB $= a$, BS $= x$, and SC $= y$. Then, by the property of the circle, y^2 ($=$ CS^2) $=$ BS $\times$ AS ($= x \times \overline{a - x}$) $= ax - x^2$; whereof the fluxion being taken, in order to determine the ratio of $\dot{x}$ and $\dot{y}$, we get $2y\dot{y} = a\dot{x} - 2x\dot{x}$; consequently $\frac{\dot{x}}{\dot{y}} = \frac{2y}{a - 2x} = \frac{y}{\frac{1}{2}a - x}$; which, multiplied by y, gives $\frac{y\dot{x}}{\dot{y}} = \frac{y^2}{\frac{1}{2}a - x} =$ the sub-tangent ST. Whence, O being supposed the centre, we have OS ($= \frac{1}{2}a - x$) : CS ($= y$) :: CS ($= y$) : ST; which is also found to be the case from other principles.

Example II. To draw a tangent to any given point C (fig. 230) of the conical parabola ACG. If the latus rectum of the curve is denoted by a, the ordinate MC by y, and its corresponding absciss AM by x; then the known equation expressing the relation of x and y, being $ax = y^2$, we have, in this case, the fluxion $a\dot{x} = 2y\dot{y}$; whence $\frac{\dot{x}}{\dot{y}} = \frac{2y}{a}$, and consequently $\frac{y\dot{x}}{\dot{y}} = \frac{2y^2}{a} = \frac{2ax}{a}, = 2x =$ MF. Therefore the sub-tangent is just the double of its corresponding absciss AM.

TANNING is the art of converting the raw skins of animals into leather. See TAN, and CUTIS.

In a preceding article (TAN), it was stated that gelatine with tannin, or the tanning principle of vegetables, formed a combination which is insoluble in water. Upon this depends the art of making leather; the gelatinous part of the skin combining with the tannin of the bark usually employed.

The process which has long been used in this country is as follows: The leather tanned in England consists chiefly of three sorts, known by the name of butts or backs, hides, and skins. Butts are generally made from the stoutest and heaviest ox-hides, and are managed as follows: after the horns are taken off, the hides are laid smooth in heaps for one or two days in the summer, and for five or six in the winter; they are then hung on poles in a close room, called a smoke-house, in which is kept a smouldering fire of wet tan; this occasions a small degree of putrefaction, by which means the hair is easily got off, by spreading the hide on a sort of wooden horse or beam, and scraping it with a crooked knife. The hair being taken off, the hide is thrown into a pit or pool of water, to cleanse it from the dirt, &c. which being done, the hide is again spread on the wooden beam, and the grease, loose flesh, extraneous filth, &c. carefully scrubbed out or taken off; the hides are then put into a pit of strong liquor, called ooze, prepared in pits kept for the purpose, by infusing ground bark in water; this is termed colouring; after which they are removed into another pit, called a scowering, which consists of water strongly impregnated with vitriolic acid, or with a vegetable acid prepared from rye or barley. This operation (which is called raising), by distending the pores of the hides, occasions them more readily to imbibe the ooze, the effect of which is to combine with the gelatinous part of the skin, and form with it leather. The hides are then taken out of the scowering, and spread smooth in a pit commonly filled with water, called a binder, with a quantity of ground bark strewed between each. After lying a month or six weeks, they are taken up; and the decayed bark and liquor being drawn out of the pit, it is filled again with strong ooze, when they are put in as before, with bark between each hide. They now lie two or three months, at the expiration of which the same operation is repeated; th y then remain four or five months, when they again undergo the same process, and after being three months in the last pit, are completely tanned; unless the hides are so remarkably stout as to want an additional pit or layer. The whole process requires from eleven to eighteen months, and sometimes two years, according to the substance of the hide, and discretion of the tanner. When taken out of the pit to be dried, they are hung on poles; and after being compressed by a steel pin, and beaten out smooth by wooden hammers, called battes, the operation is complete; and when thoroughly dry, they are fit for sale. Butts are chiefly used for the soles of stout shoes.

The leather which goes under the denomination of hides, is generally made of cow-hides, or the lighter ox-hides, which are thus managed: After the horns are taken off, and the hides washed, they are put into a pit of water, saturated with lime; where they remain a few days, when they are taken out, and the hair scraped off on a wooden beam, as before described; they are then washed in a pit or pool of water, and the loose flesh, &c. being taken off, they are removed into a pit of weak ooze, where they are taken up and put down (which is technically termed handling) two or three times a day, for the first week; every second or third day they are shifted into a pit of fresh ooze, somewhat stronger than the former, till at the end of a month or six weeks they are put into a strong ooze, in which they are handled once or twice a week with fresh bark for two or three months. They are then removed into another pit, called a layer, in which they are laid smooth, with bark ground very fine, strewed between each hide. After remaining here two or three months, they are generally taken up, when the ooze is drawn out, and the hides put in again with fresh ooze and fresh bark, where, after lying two or three months more, they are completely tanned; except a very few stout hides, which may require an extra layer: they are then taken out, and hung on poles, and being hammered and smoothed by a steel pin, are, when dry, fit for sale. These hides are called crop hides; they are from ten to eighteen months in tanning, and are used for the soles of shoes.

Skins is the general term for the skins of calves, seals, hogs, dogs, &c. These, after being washed in water, are put into lime-pits, as before mentioned, where they are taken up and put down every third or fourth day, for a fortnight or three weeks, in order to destroy the epidermis of the skin. The hair is then scraped off, and the excrescences being removed, they are put into a pit of water impregnated with pigeon-dung, called a grainer, forming an alkaline ley, which in a week or ten days soaking out the lime, grease, and saponaceous matter (during which period they are several times scraped over with a crooked knife, to work out the dirt and filth), softens the skins, and prepares them for the reception of the ooze. They are then put into a pit of weak ooze, in the same manner as the hides, and being frequently handled, are by degrees removed into a stronger, and still stronger liquor, for a month or six weeks; when they are put into a very strong ooze, with fresh bark ground very fine, and at the end of two or three months, according to their substances, are sufficiently tanned; when they are taken out, hung on poles, dried, and are fit for sale. These skins are afterwards dressed and blacked by the curriers, and are used for the upper leathers of shoes, boots, &c.

The lighter sort of hides, called dressing hides, as well as horse-hides, are managed nearly in the same manner as skins; and are used for coach-work, harness-work, &c. &c.

Much light has been thrown by modern chemists upon the theory of tanning, though it does not appear that any considerable improvements have been made in the practice of this art. M. Seguin, in France, has particularly distinguished himself by his researches on this subject.

In 1795, Mr. William Desmond obtained a patent for practising Seguin's method in England. He obtained the tanning principle by digesting oak-bark or other proper material in cold water, in an apparatus nearly similar to that used in the saltpetre-works. That is, the water which has remained upon the powdered bark for some time, in one vessel, is drawn off by a cock, and poured upon fresh tan. This is again to be drawn off, and poured upon other fresh tan; and in this way the process is to be continued to the fifth vessel. The liquor is then highly coloured, and marks from six to eight degrees upon the hydrometer for salts. This he calls the tanning lixivium.

The criterion for ascertaining its strength, is the quantity of the solution of gelatine which a given quantity of it will precipitate. Isinglass is used for this purpose, being entirely composed of gelatine. And here it may be observed, that this is the mode of ascertaining the quantity of tanning principle in any vegetable substance, and consequently how far each may be used as a substitute for oak-bark.

The hides, after being prepared in the usual way, are immersed for some hours in a weak tanning lixivium of only one or two degrees; to obtain which, the latter portions of the infusions are set apart, or else some of that which has been partly exhausted by use in tanning. The hides are then to be put into a stronger lixivium, where, in a few days, they will be brought to the same degree of saturation with the liquor in which they are immersed. The strength of the liquor will by this means be considerably diminished, and must therefore be renewed. When the hides are by this means completely saturated, that is, perfectly tanned, they are to be removed, and slowly dried in the shade.

It has been proposed to use the residuum of the tanning lixivium, or the exhausted ooze (which contains a portion of gallic acid, this forming a constituent part of astringent vegetables), for the purpose of taking off the hair; but this liquor seems to contain no substances capable of acting upon the epidermis, or of loosening the hair; and when skin is depilated by being exposed to it, the effect must really be owing to incipient putrefaction.

The length of time necessary to tan leather completely, according to the old process, is certainly a very great inconvenience; and there is no doubt that it may be much shortened by following the new method. It has been found, however, that the leather so tanned has not been so durable as that which has been formed by a slower process.

TANTALITE. This mineral has been found in Finland, in the parish of Kimito. It has been long known; but before the analysis of Ekeberg, was mistaken for an ore of tin. Found in irregular crystals, which seem to be octahedrons. Colour between bluish grey and blackish grey. Surface smooth, with some lustre. Lustre metallic. Fracture compact. Streak blackish grey, approaching brown. Very hard. Not magnetic. Specific gravity 7.953. Composed of the oxides of tantalium, iron, and manganese.

TANTALIUM. Mr. Ekeberg, a Swedish chemist of considerable eminence, has lately discovered a new metal constituting a component part of two minerals, found in the parish of Kimito in Finland. The first of these minerals, which he calls tantalite, has a bluish or blackish grey colour, crystallized confusedly, with a metallic lustre and compact fracture. It is very hard, and its specific gravity is 7.953. It has been long known, and mistaken for an ore of tin.

The other mineral, called yttro-tantalite, is found in small kidney-form masses. It is of a deep-grey colour, has a metallic lustre, and a granular fracture. It is not hard. Its specific gravity is 5.130.

From each of these minerals Mr. Ekeberg extracted, by a chemical analysis, a white powder, which he ascertained to be the oxide of a peculiar metal, to which he gave the name of tantalium.

When this white oxide of tantalium is strongly heated along with charcoal in a crucible, it yields a button moderately hard, which has the metallic lustre externally, but within is black and destitute of brilliancy. The acids convert it again into the state of white-coloured oxide.

This oxide does not alter its colour, though heated to redness. Its specific gravity is 6.500. It is not acted on by acids, nor is it soluble in any of them. It was this insolubility in acids which induced Ekeberg to give it the name of tantalium, from the fabled punishment of Tantalus.

This oxide combines with the alkalies except ammonia, and forms with them compounds soluble in water. When melted with phosphat of soda and borax, it forms with them glasses destitute of colour. Such are the only properties of this metal hitherto published.

The resemblance between the oxides of tantalium and columbium is striking. The only property in which they differ is, the insolubility of the first in acids; but we know not what acids Ekeberg tried, and Mr. Hatchett found the oxide of columbium insoluble in nitric acid.

TANTALUS, or Ibis, a genus of birds of the order grallæ. The generic character is, bill long, subulate, roundish subarched; face naked; nostrils oval; feet four-toed, palmate at the base. There are 23 species; the most remarkable are:

1. The loculator, or wood ibis: (1.) face bluish; bill reddish; legs, quill and tail feathers, black; body white. (2.) Head and neck white, varied with yellow; body black; belly cinereous. (3.) Wing-coverts white, with a black blotch in the middle. Inhabits New Holland, and the warmer parts of America. It is three feet long; is very slow in flight, and stupid; sits on trees, and feeds on herbs, seeds, fruits, fish, and reptiles. The flesh is very much esteemed.

2. The leucephalus, or white-headed ibis, inhabits India; and every year before the rainy season sets in, it sheds its rosy feathers.

3. The ibis, or Egyptian ibis, inhabits in vast numbers the lower part of Egypt, and is held sacred by the inhabitants for its use in clearing the land of reptiles and insects, which are left after the inundation of the Nile. It rests in an erect posture, and is said to destroy the young of the crocodile.

4. The melanocephalus, or black-headed ibis, is a very beautiful bird that inhabits India. See Plate Nat. Hist. fig. 391.

TANTALUS'S CUP. See HYDRAULICS.

TAPE-WORM. See TÆNIA.

TAPESTRY, a kind of woven hangings of wool and silk, frequently raised and enriched with gold and silver, representing figures of men, animals, landscapes, histories, &c.

The invention of tapestry seems to have come to us from the Levant; and this appears the more probable, as the workmen concerned in it were called, at least in France, sarrasins, or sorrasinois. It is supposed that the English and Flemish, who were the first that excelled in making tapestry, might bring the art with them from some of the crusades, or expeditions against the Saracens.

Tapestry-work is distinguished by the workmen into two kinds, viz. that of high, and that of low warp; though the difference is rather in the manner of working than in the work itself, which is in effect the same in both, only the looms, and consequently the warps, are differently situated: those of the low warp being placed flat and parallel to the horizon, and those, on the contrary, of the high warp, erected perpendicularly. The English antiently excelled all the world in the tapestry of the high warp.

The manufacture of tapestry of the high warp. The loom, whereon it is wrought, is placed perpendicularly. It consists of four principal pieces; two long planks or cheeks of wood, and two thick rollers or beams. The planks are set upright, and the beams across them, one at the top, and the other at the bottom, or about a foot distance from the ground. They have each their trunnions, by which they are suspended on the planks, and are turned with bars. In each roller is a groove from one end to the other, capable of containing a long round piece of wood, fastened therein with hooks. The use of it is to tie the ends of the warp to. The warp, which is a kind of worsted, or twisted woollen thread, is wound on the upper roller; and the work, as fast as woven, is wound on the lower. Withinside the planks, which are seven or eight feet high, 14 or 15 inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at one end, serving to sustain the coat-stave: these pieces of iron have also holes pierced, by putting a pin in which, the stave is drawn nearer or set further off; and thus the coats or threads are stretched or loosened at pleasure. The coat-stave is about three inches diameter, and runs all the length of the loom; on this are fixed the coats or threads, which make the threads of the warp cross each other. It has much the same effect here, as the spring-stave and treadles have in the common looms. The coats are little threads fastened to each thread of the warp with a kind of sliding knot, which forms a sort of mesh or ring. They serve to keep the warp open for the passage of broaches wound with silks, woollens, or other matters used in the piece of tapestry. In the last place, there are a number of little sticks of different lengths, but all about an inch in diameter, which the workman keeps by him in baskets, to serve to make the threads of the warp cross each other, by passing them across; and, that the threads thus crossed may retain their proper situation, a packthread is run among the threads, above the stick.

The loom being thus formed, and mounted with its warp, the first thing the workman does, is to draw on the threads of this warp, the principal lines and strokes of the design to be represented on the piece of tapestry; which is done by applying cartoons, made from the painting he intends to copy, to the side that is to be the wrong side of the piece, and then, with a black-lead pencil, following and tracing out the contours thereof on the thread of the right side, so that the strokes appear equally both before and behind.

As for the original design the work is to be finished by, it is hung up behind the workmen, and wound on a long staff, from which a piece is unrolled from time to time as the work proceeds.

Besides the loom, &c. here described, there are three other principal instruments required for working the silk or the wool of the woof within the threads of the warp; these are a broach, a reed, and an iron needle.

The broach is made of a hard wood, seven or eight inches long, and two-thirds of an inch thick, ending in a point with a little handle. This serves as a shuttle; the silks, woollens, gold, or silver, to be used in the work, being wound on it,

The reed or comb is also of wood, eight or nine inches long, and an inch thick on the back, whence it grows less and less to the extremity of the teeth, which are more or less apart, according to the greater or less degree of fineness of the intended work. Lastly, the needle is made in form of the common needle, only larger and longer. Its use is to press close the wool and silks when there is any line or colour that does not fit well.

All things being prepared for the work, and the workman ready to begin, he places himself on the wrong side of the piece, with his back towards the design; so that he works in a manner blindfold, seeing nothing of what he does, and being obliged to quit his post, and go to the other side of the loom, whenever he would view and examine the piece, to correct it with his pressing-needle. To put silk, &c. in the warp, he first turns and looks at the design; then, taking a broachful of the proper colour, he places it among the threads of the warp, which he brings cross each other with his fingers, by means of the coats or threads fastened to the staff; this he repeats every time he is to change his colour. Having placed the silk or wool, he beats it with his reed or comb; and when he has thus wrought in several rows over each other, he goes to see the effects they have, in order to reform the contours with his needle, if there should be occasion. As the work advances, it is rolled upon the lower beam, and they unrol as much warp from the upper beam as suffices them to continue the piece; the like they do of the design behind them. When the pieces are wide, several workmen may be employed at once.

We have two things to add: the first is, that the high-warp tapestry goes on much more slowly than the low-warp, and takes up almost twice the time and trouble. The second is, that all the difference that the eye can perceive between the two kinds, consists in this; that in the low warp there is a red fillet, about one-twelfth of an inch broad, running on each side from top to bottom, which is wanting in the high warp.

But, for the satisfaction of our readers, we shall here describe the principal parts of the loom for the manufacture of tapestry of the high warp, or that in a situation perpendicular to the horizon. The loom consists, 1. Of two strong upright posts fixed in the floor: these support (2.) two rollers, of which the upper end holds the chain, the lower holds the tapestry, which is rolled upon it according as the work goes forward: the threads are fastened at their ends to a dweet, or thick rod, which is lodged in a groove made on each roller. 3. The two tantoes, one called the great tantoe, for turning the upper roller; the other, the little tantoe, for turning the lower roller. 4. The pole of the leishes, which runs quite across the chain, takes up all the leishes, and brings them to the workman's hand. These leishes are little strings, tied by a slip-knot to each thread of the chain, to be raised up according as the chain sinks down: they serve to draw the particular thread which the weaver wants. He holds the thread separate from the rest, and passes a spindle of such a woof and colour as he thinks proper; then he lets the spindle hang down, and hinders the thread from running off by a slip-knot. After having taken one or two threads of the fore part of the chain by another leish, he brings the threads of the opposite side to him. By this alternative work he constantly makes them cross one another, to take in and secure the woof. In order to distinguish the threads of both sides, he is assisted by the cross rod, which is put between two rows of threads. 5. A long tract of dots formed by the ends of the leishes which take hold of the leishes of the chain by a slip-knot; and on the other hand encompass the pole of the leishes. 6. The cross-rod. 7. A little chain, each loop of which contains four or five threads of the warp, and keeps them perpendicular. 8. An iron hook, to support the pole of the leishes. 9, The broacher-quill, to pass the threads of the woof, which is wound on it. 10. The comb, to strike in the work. 11. The end of the dweet let into the roller, in a groove.

When the chain is mounted, the draughtsman traces the principal outlines of the picture, which is to be wrought with black chalk on the fore and back side of the chain. The weaver in the upright way having prepared a good stock of quills, filled with threads of all colours, goes to work, placed on the back part, as in the flat way, or in the manufacture of the low warp. He has behind him his drawings, on which he frequently looks, that he may from time to time see how his work succeeds on the right or fore side, which the other cannot do.

TAPIR, a genus of quadrupeds of the order belluæ. The generic character is, front teeth in both jaws, ten; canine teeth in both jaws, single, incurvated; grinders in both jaws, five on each side, very broad; feet with three hoofs, and a false hoof on the fore feet.

Tapir Americanus, American tapir. The tapir, with respect to the size of its body, may be considered as the largest of all the native quadrupeds of South America, except the lately discovered equus bisulcus of Molina. When full-grown it is nearly equal to a heifer. In its general form it bears some distant resemblance to the hippopotamus, and in the earlier editions of the Systema Naturæ was ranked by Linnæus in that genus, under the title of hippopotamus terrestris. By others it has been considered as more allied to the hog, and has been called sus aquaticus multisulcus, or water-hog with fingered hoof; but, in reality, the tapir cannot properly be associated, otherwise than by a distant general alliance, with any other quadruped, and forms a peculiar genus. It is of a gregarious nature, and inhabits the woods and rivers of the eastern parts of South America; occurring from the isthmus of Darien to the river Amazons; feeding chiefly by night, and eating sugar-canes, grasses, and various kinds of fruit. Its colour is an obscure brown, the skin itself being of that cast, and covered sparingly with somewhat short hair; the young animal is said to be commonly spotted with white. The male is distinguished by a kind of short proboscis or trunk, formed by the prolongation of the upper lip to some distance beyond the lower: this part is extensile, wrinkled at the sides, and in some degree resembles that of the elephant on a smaller scale, though not of the same tubular structure. The neck is very short, and furnished above with a rising mane; the body is thick and heavy; the back much arched; the legs short; the fore feet divided into four toes with pointed hoofs; the hind into three only; the tail is very short, thickish, and pointed. The female is said to be destitute of the proboscis.

In its manners this animal is perfectly harmless; endeavouring merely to save itself by flight when pursued, plunging into some river if at hand, and swimming with great readiness, and even continuing for a considerable time under water, in the manner of the hippopotamus. The young is easily tamed, and may be rendered domestic, as is said to be the case in some parts of Guiana. In feeding, the tapir makes use of the trunk in the same manner as the rhinoceros of its upper lip, to grasp the stems of plants, leaves, &c. Its most common attitude, when at rest, is sitting on its rump, in the manner of dog.

The tapir has been occasionally imported alive into Europe. The flesh is considered by the South Americans as a wholesome food, though not very pleasant or delicate, and the skin serves for various purposes where a strong leather is required. The Indians make shields of it, which are said to be so hard that an arrow cannot pierce them. This animal sleeps much by day in the retired parts of the woods, and is shot by the Indians with poisoned arrows. When attacked by dogs, it is said to make a very vigorous resistance. Its voice is a kind of whistle, which is easily imitated, and thus the animal is often deceived and trepanned. It is rather slow in its motions, and of a somewhat inactive disposition.

The tapir produces but one young at a birth, of which it is extremely careful; leading it early to the water, in order to instruct it in swimming, &c. See Plate Nat. Hist. fig. 392.

TAPPING. See Surgery.

TAR. See Pinus, Resins, and Bitumen.

TARANTULA. See Aranea.

TARCHONANTHUS, *flea-bane*, a genus of plants belonging to the class of syngenesia, and to the order of polygamia æqualis, and in the natural system ranging under the 49th order, compositæ. The receptacle is villous, and the pappus plumy; the calyx is monophyllous, turbinated, and half divided into seven segments. There are only three species known; the camphoratus, glaber, and ericoides.

TARE, is an allowance for the outside package, that contains such goods as cannot be unpacked without detriment; or for the papers, threads, bands, &c. that inclose or bind any goods imported loose; or, though imported in casks, chests, &c. yet cannot be unpacked and weighed net.

TARGIONIA, a genus of plants of the class of cryptogamia, and natural order of algæ. The calyx is bivalved, including a globular body. There is only one species; the hypophylla, which is a native of Great Britain.

TARGUM, a name whereby the Jews call the Chaldee paraphrases, or expositions of the Old Testament, in the Chaldee language.

TARIF, or Tariff, a table or catalogue, containing the names of different sorts of merchandize, with the duties to be paid, as settled by authority, amongst trading nations.

TARSUS. See Anatomy.

TARTAR, or, according to the new chemistry, Tartrat of Potass, is obtained in a state of impurity, incrusted on the bottom and sides of casks in which wine has been kept. It is afterwards purified by dissolving it in boiling water, and filtring it while hot. On cooling, it deposits the pure salt in very irregular crystals. In this state it is sold under the name of crystals or cream of tartar. This salt attracted the peculiar attention of chemists, probably in consequence of the extravagant encomiums and invectives bestowed on it by Paracelsus. It is called tartar, says he, because it produces the oil, water, tincture, and salt, which burn the patient as hell does. According to him, it is the principle of every disease, and every remedy, and all things contain the germ of it. This ridiculous theory was combated by Van Helmont, who gives a pretty accurate account of the formation of tartar in wine-casks. It was known to Van Helmont, and even to his predecessors, that potass could be obtained from tartar; but it was long a disputed point among chemists, whether the alkali existed in it ready-formed. Duhamel, Margraff, and Rouelle, at last established that point beyond a doubt; but the other component part of tartar was unknown, or very imperfectly known, till Scheele pointed out the method of extracting it.

The crystals of tartar are very small and irregular. According to Mantet, they are prisms, somewhat flat, and mostly with six sides. Tartar has an acid, and rather unpleasant taste. It is very brittle, and easily reduced to powder. Its specific gravity is 1.953. It is soluble in about 60 parts of cold water, and in about 30 parts of boiling water. It is not altered by exposure to the air; but when its solution in water is allowed to remain for some time, the salt is gradually decomposed, a mucous matter is deposited, and there remains in solution carbonat of potass coloured with a little oil. This decomposition was first accurately described by Berthollet in 1782.

When tartar is heated, it melts, swells, blackens, and the acid is entirely decomposed. The same changes take place when the salt is distilled in close vessels. The phenomena of this distillation have been described with great care, and its products very attentively examined, by chemists; because, before the discovery of the tartaric acid by Scheele, distillation was the only method thought of for obtaining any knowledge of the acid part of tartar. These products are an enormous quantity of gas, consisting of carbonic acid and carbureted hydrogen, an oil, and an acid; and, according to some chemists, carbonat of ammonia. The acid obtained was long considered as a peculiar body, and was denominated pyro-tartarous acid by the French chemists in 1787. But Fourcroy and Vauquelin have lately demonstrated, that it is no other than acetic acid contaminated with a little empyreumatic oil.

Tartar, according to Bergman, is composed of

	77 acid
	23 potass
	100.
Or - - -	56 tartrat of potass
	44 tartaric acid
	100.

According to the late analysis of Tenard, its component parts are

57 acid
33 potass
7 water

97.

TARTARIC ACID. Scheele was the first who obtained this acid in a separate state. He communicated his process for obtaining it to Retzius, who published it in the Stockholm Transactions for 1770. It consisted in boiling tartar with lime, and in decomposing the tartrat of lime thus formed by means of sulphuric acid.

1. The process employed at present for obtaining tartaric acid, which is the same with that of Scheele, is the following: Dissolve tartar in boiling water, and add to the solution powdered chalk till all effervescence ceases, and the liquid ceases to redden vegetable blues. Let the liquid cool, and then pass it through a filtre. A quantity of tartrat of lime (which is an insoluble white powder) remains upon the filtre. Put this tartrat, previously well washed, into a glass cucurbite, and pour on it a quantity of sulphuric acid equal to the weight of the chalk employed, which must be diluted with water. Allow it to digest for twelve hours, stirring it occasionally. The sulphuric acid displaces the tartaric; sulphat of lime remains at the bottom, while the tartaric acid is dissolved in the liquid part. Decant off this last, and try whether it contains any sulphuric acid. This is done by dropping in a little acetat of lead; a precipitate appears, which is insoluble in acetic acid if sulphuric acid is present, but soluble if it is absent. If sulphuric acid is present, the liquid must be digested again on some more tartrat of lime; if not, it is to be slowly evaporated, and about one-third part of the weight of the tartar employed is obtained of crystallized tartaric acid.

2. The form of its crystals is so irregular, that every chemist who has treated of this subject has given a different description of them. According to Bergman, they generally consist of divaricating lamellæ; according to Van Packen, they assume oftenest the form of long-pointed prisms; Spielman and Corvinus obtained them in groups, some of them lance-shaped, others needle-formed, others pyramidal. Morveau obtained them needle-form. Their specific gravity is 1.5962.

3. Crystallized tartaric acid does not experience any change in the open air, but heat decomposes it altogether: in the open fire it burns without leaving any other residuum than a spungy charcoal, which generally contains a little lime. When distilled in close vessels, it is converted into carbonic acid gas and carbureted hydrogen gas, a coloured oil, and a reddish acid liquor, which was formerly distinguished by the name of pyrotartarous acid, but which Fourcroy and Vauquelin have lately ascertained to be merely acetic acid impregnated with oil.

4. Tartaric acid dissolves readily in water. Bergman obtained a solution, the specific gravity of which was 1.230. Morveau observed, however, that crystals formed spontaneously in a solution, the specific gravity of which was 1.084. It is not liable to spontaneous decomposition when dissolved in water, unless the solution is considerably diluted.

5. Neither its action on oxygen gas nor on simple combustibles and incombustibles has been examined; but it is probable that it is not capable of producing any sensible change on them. It is capable of oxidizing iron and zinc, and even mercury; but it does not act

upon antimony, bismuth, tin, lead, copper, silver, gold, or platinum. Its action on the other metallic bodies has scarcely been examined.

6. It combines with alkalies, earths, and metallic oxides, and forms salts known by the name of tartrats.

7. The action of the greater part of the other acids on it is unknown. Hermstadt has ascertained, that it may be converted into oxalic acid by distilling it repeatedly with six times its weight of nitric acid. By this process he obtained 560 parts of oxalic acid from 360 parts of tartaric acid.

8. From this result, and from the products obtained when tartaric acid is distilled, it is evident that it is composed of oxygen, carbon, and hydrogen. Fourcroy informs us, that Vauquelin and he have ascertained that these ingredients are combined in it the following proportions:

70.5 oxygen
19.0 carbon
10.5 hydrogen

100.0

9. The affinities of this acid follow the same order as those of oxalic acid.

Tartaric acid, in a state of purity, has scarcely been put to any use; but some of the compounds into which it enters are much employed in medicine. This acid has the property of combining in two different proportions with a great number of bases. With potass, for instance, in one proportion, it forms a salt pretty soluble in water, called tartrat of potass; but when added in a greater proportion, it forms tartar, a salt very imperfectly soluble in water. By this property, the presence of tartaric acid, in any acid solution, may easily be detected. All that is necessary is, to drop in slowly a little solution of potass; if tartaric acid is present, tartar immediately precipitates in the form of a white gritty powder.

TARTRATS, salts formed with the tartaric acid.

TAURUS. See ASTRONOMY.

TAX. See REVENUE, CUSTOMS, &c.

TAXUS, the YEW-TREE, a genus of plants of the class of diœcia, and order of monadelphia; and in the natural system ranging under the 51st order, coniferæ. There is no male calyx or corolla; the stamina are numerous; the antheræ peltated and octofid. The female has no corolla nor style, and only one seed with a calycle resembling a berry very entire. There are four species; of which the baccata, or common yew-tree, is a native of Britain, France, Switzerland, &c. and of North America. It is distinguished from the other species by linear leaves which grow very close, and by the receptacles of the male flowers being subglobose. The wood is reddish, full of veins, and flexible, very hard and smooth, and almost incorruptible. Its hardness renders it very proper for turners and cabinet-makers. Its berries are often eaten by birds, and are therefore not poisonous; but it is a common opinion that the leaves are poisonous to cattle, and many facts are mentioned of horses and cows having eaten them. Others, however, deny these facts. It is of no great height, but the trunk grows to a large size. Mr. Pennant has taken notice of a very remarkable decayed one in Fortingal church-yard, the remains of which measured fifty-six feet and a half in circumference.

TEARS, and MUCUS. 1. That peculiar fluid which is employed in lubricating the eye, and which is emitted in considerable quantities when we express grief by weeping, is known by the name of tears. For an accurate analyis of this fluid, we are indebted to Messrs. Fourcroy and Vauquelin. Before their dissertation, which was published in 1791, appeared, scarcely was any thing known about the nature of tears.

The liquid called tears is transparent and colourless like water; it has scarcely any smell, but its taste is always perceptibly salt. Its specific gravity is somewhat greater than that of distilled water. It gives to paper, stained with the juice of the petals of mallows or violets, a permanently green colour, and therefore contains a fixed alkali. It unites with water, whether cold or hot, in all proportions. Alkalies unite with it readily, and render it more fluid. The mineral acids produce no apparent change upon it. Exposed to the air, this liquid gradually evaporates, and becomes thicker. When nearly reduced to a state of dryness, a number of cubic crystals form in the midst of a kind of mucilage. These crystals possess the properties of muriat of soda; but they tinge vegetable blues green, and therefore contain an excess of soda. The mucilaginous matter acquires a yellowish colour as it dries.

This liquid boils like water, excepting that a considerable froth collects on its surface. If it is kept a sufficient time at the boiling temperature, $\frac{96}{100}$ parts of it evaporate in water; and there remain about 0.4 parts of a yellowish matter, which by distillation in a strong heat yields water and a little oil; the residuum consists of different saline matters.

When alcohol is poured into this liquid, a mucilaginous matter is precipitated in the form of large white flakes. The alcohol leaves behind it, when evaporated, traces of muriat of soda, and soda. The residuum which remains behind, when inspissated tears are burnt in the open air, exhibits some traces of phosphat of lime and phosphat of soda.

Thus it appears that tears are composed of the following ingredients:

1. Water,	4. Soda,
2. Mucilage,	5. Phosphat of lime,
3. Muriat of soda,	6. Phosphat of soda.

The saline parts amount only to about 0.01 of the whole, or probably not so much.

The mucilage contained in the tears has the property of absorbing oxygen gradually from the atmosphere, and of becoming thick and viscid, and of a yellow colour. It is then insoluble in water, and remains long suspended in it without alteration. When a sufficient quantity of oxymuriatic acid is poured into tears, a yellow flaky precipitate appears, absolutely similar to this inspissated mucilage. The oxymuriatic acid loses its peculiar odour; hence it is evident that it has given out oxygen to the mucilage. The property which this mucilage has of absorbing oxygen, and of acquiring new qualities, explains the changes which take place in tears which are exposed for a long time to the action of the atmosphere, as is the case in those persons who labour under a fistula lachrymalis.

2. The mucus of the nose has also been examined by Fourcroy and Vauquelin. They found it composed of precisely the same ingredients with the tears. As this fluid is more exposed to the action of the air than the tears, in most cases its mucilage has undergone less or more of that change which is the consequence of the absorption of oxygen. See MUCUS.

TECTONA, a genus of the pentandria monogynia class and order. The corolla is five-cleft; stigma toothed; drupe dry, spungy within the inflated calyx; nect. three-celled. There is one species, the teck-wood, or Indian oak, a tree of the East Indies.

TELEGRAPH, an instrument by means of which information may be quickly conveyed to a considerable distance. The telegraph is by no means a modern invention. There is reason to believe that amongst the Greeks there was some sort of telegraph in use. A Greek play begins with a scene, in which a watchman descends from the top of a tower in Greece, and gives the information that Troy was taken. "I have been looking out these ten years (says he) to see when that would happen, and this night it is done." Of the antiquity of a mode of conveying intelligence quickly to a great distance, this is certainly a proof. The Chinese when they send couriers on the great canal, or when any great man travels there, make signals by fire from one day's journey to another, to have every thing prepared; and most of the barbarous nations used formerly to give the alarm of war by fires lighted on the hills or rising grounds.

In the year 1663, the marquis of Worcester, in his Century of Inventions, affirmed that he had discovered "a method by which, at a window, as far as eye can discover black from white, a man may hold discourse with his correspondent, without noise made or notice taken; being according to occasion given, or means afforded, ex re nata, and no need of provision beforehand; though much better if foreseen, and course taken by mutual consent of parties." This could be done only by means of a telegraph, which in the next sentence is declared to have been rendered so perfect, that by means of it the correspondence could be carried on "by night as well as by day, though as dark as pitch is black."

About forty years afterwards M. Amontons proposed a new telegraph. His method was this: Let there be people placed in several stations, at a certain distance from one another, that by the help of a telescope a man in one station may see a signal made in the next before him; he must immediately make the same signal, that it may be seen by persons in the station next after him, who are to communicate it to those in the following station, &c. These signals may be as letters of the alphabet, or as a cypher, understood only by the two persons who are in the distant places, and not by those who make the signals. The person in the second station making the signal to the person in the third the very moment he sees it in the first, the news may be carried to the greatest distance in as little time as is necessary to make the signals in the first station. The distance of the several stations, which must be as few as possible, is measured by the reach of a telescope. Amontons tried this method in a mall tract of land before several persons of the highest rank at the court of France.

It was not, however, till the French revolution, that the telegraph was applied generally to useful purposes. Whether M. Chappe, who is said to have invented the telegraph first used by the French about the end of 1793, knew any thing of Amontons' invention or not, it is impossible to say; but his telegraph was constructed on principles nearly similar. The manner of using this telegraph was as follows: At the first station, which was on the roof of the palace of the Louvre at Paris, M. Chappe, the inventor, received in writing, from the committee of public welfare, the words to be sent to Lisle, near which the French army at that time was. An upright post was erected on the Louvre, at the top of which were two transverse arms, moveable in all directions by a single piece of mechanism, and with inconceivable rapidity. He invented a number of positions for these arms, which stood as signs for the letters of the alphabet; and these, for the greater celerity and simplicity, he reduced in number as much as possible. The grammarian will easily conceive that sixteen signs may amply supply all the letters of the alphabet, since some letters may be omitted not only without detriment but with advantage. These signs, as they were arbitrary, could be changed every week; so that the sign of B for one day might be the sign of M the next; and it was only necessary that the persons at the extremities should know the key. The intermediate operators were only instructed generally in these sixteen signals; which were so distinct, so marked, so different the one from the other, that they were easily remembered. The construction of the machine was such, that each signal was uniformly given in precisely the same manner at all times; it did not depend on the operator's manual skill; and the position of the arm could never, for any one signal, be a degree higher or a degree lower, its movement being regulated mechanically.

M. Chappe, having received at the Louvre the sentence to be conveyed, gave a known signal to the second station, which was Mont Martre, to prepare. At each station there was a watch-tower, where telescopes were fixed, and the person on watch gave the signal of preparation which he had received, and this communicated successively through all the line, which brought them all into a state of readiness. The person at Mont Martre then received, letter by letter, the sentence from the Louvre, which he repeated with his own machine; and this was again repeated from the next height, with inconceivable rapidity, to the final station at Lisle.

The first description of the telegraph was brought from Paris to Franckfort on the Maine by a former member of the parliament of Bourdeaux, who had seen that which was erected on the mountain of Belville. As given by Dr. Hutton from some of the English papers, it is as follows: AA is a beam or mast of wood placed upright on a rising ground (Plate Miscel. fig. 231), which is about 15 or 16 feet high. BB is a beam or balance-beam moving upon the centre AA. This balance-beam may be placed vertically or horizontally, or any how inclined, by means of strong cords, which are fixed to the wheel D, on the edge of which is a double groove to receive the two cords. This balance is about eleven or twelve feet long, and nine inches broad, having at the ends two pieces of wood CC, which likewise turn upon angles by means of four other cords that pass through the axis of the main balance, otherwise the balance would derange the cords; the pieces C are each about three feet long, and may be placed either to the right or left, straight, or square with the balance-beam. By means of these three the combination of movement is very extensive, remarkably simple, and easy to perform. Below is a small wooden hut, in which a person is employed to observe the movements of the machine. On the eminence nearest to this, another person is to repeat these movements, and a third to write them down. The time taken up for each movement is twenty seconds; of which the motion alone is four seconds, the other sixteen the machine is stationary. Two working models of this instrument were executed at Frankfort, and sent by Mr. W. Playfair to the duke of York; and hence the plan and alphabet of the machine came to England.

Various experiments were in consequence tried upon telegraphs in this country; and one was soon after set up by government in a chain of stations from the admiralty-office to the sea-coast. It consists of six octagon-boards, each of which is poised upon an axis in a frame, in such a manner that it can be either placed vertically, so as to appear with its full size to the observer at the nearest station as in fig. 232, or it becomes invisible to him by being placed horizontally, as in fig. 233, so that the narrow edge alone is exposed, which narrow edge is from a distance invisible. Fig. 232 is a representation of this telegraph, with the parts all shut, and the machine ready to work. T, in the officer's cabin, is the telescope pointed to the next station. Fig. 233 is a representation of the machine not at work, and with the ports all open. The opening of the first port expresses *a*, the second *b*, the third *c*, the fourth *d*, the fifth *e*, and the sixth *f*, &c.

Six boards make 36 changes, by the most plain and simple mode of working; and they will make 27 more if more were necessary; but as the real superiority of the telegraph over all other modes of making signals consists in its making letters, we do not think that more changes than the letters of the alphabet, and the ten arithmetical cyphers, are necessary; but, on the contrary, that those who work the telegraphs should avoid communicate by words or signs agreed upon to express sentences; for that is the sure method never to become expert at sending unexpected intelligence accurately.

This telegraph is, without doubt, made up of the best number of combinations possible; five boards would be insufficient, and seven would be useless. It has been objected to it, however, that its form is too clumsy to admit of its being raised to any considerable height above the building on which it stands; and that it cannot be made to change its direction, and consequently cannot be seen but from one particular point.

Several other telegraphs have been proposed to remedy these defects, and perhaps others to which the instrument is still liable. The dial-plate of a clock would make an excellent telegraph, as it might exhibit 144 signs so as to be visible at a great distance. A telegraph on this principle, with only six divisions instead of twelve, would be simple and cheap, and might be raised twenty or thirty feet high above the building without any difficulty: it might be supported on one post, and therefore turn round, and the contrast of colours would always be the same.

We shall now conclude this article with a short idea of Mr. John Garnet's most simple and ingenious contrivance. This is merely a bar or plank turning upon a centre, like the sail of a windmill; and being moved into any position, the distant observer turns the tube of a telescope into the same position, by bringing a fixed wire within it to coincide with or parallel to the bar, which is a thing extremely easy to do. The centre of motion of the bar has a small circle about it, with letters and figures around the circumference, and an index moving round with the bar, pointing to any letter or mark that the operator wishes to set the bar to, or to communicate to the observer. The eye-end of the telescope without has a like index and circle, with the corresponding letters or other marks. The consequence is obvious; the telescope being turned round till its wire covers or becomes parallel to the bar, the index of the former necessarily points out the same letter or mark in its circle, as that of the latter, and the communication of sentiment is immediate and perfect. The use of this machine is so easy, that it has been put into the hands of two common labouring-men, who had never seen it before, and they have immediately held a quick and distant conversation together.

The more particular description and figure of this machine, are as follows. ABDE (fig. 234) is the telegraph, on whose centre of gravity C, about which it revolves, is a fixed pin, which goes through a hole or socket in the firm upright post G, and on the opposite side of which is fixed an index CI. Concentric to C, on the same post, is fixed a wooden or brass circle, of six or eight inches diameter, divided into forty-eight equal parts, twenty-four of which represent the letters of the alphabet, and between the letters, numbers; so that the index, by means of the arm AB, may be moved to any letter or number. The length of the arm should be $2\frac{1}{2}$ or 3 feet for every mile of distance. Two revolving lamps of different colours suspended occasionally at A and B, the ends of the arm, would serve equally at night.

Let *ss* (fig. 235) represent the section of the outward tube of a telescope perpendicular to its axis, and *xx* the like section of the sliding or adjusting tube, on which is fixed an index I I. On the part of the outward tube next to the observer, there is fixed a circle of letters and numbers, similarly divided and situated to the circle in fig. 234; then the index I I, by means of the sliding or adjusting tube, may be turned to any letter or number. Now there being a cross hair, or fine silver wire, *fg*, fixed in the focus of the eye-glass, in the same direction as the index II; so that when the arm AB (fig. 234) of the telegraph is viewed at a distance through the telescope, the cross hair may be turned, by means of the sliding tube, to the same direction of the arm AB; then the index I I (fig. 235) will point to the same letter or number on its own circle, as the index I (fig. 234) points to on the telegraphic circle.

If, instead of using the letters and numbers to form words at length, they are used as signals, three motions of the arm will give above a hundred thousand different signals.

TELEPHIUM, TRUE ORPINE; a genus of plants of the class of pentandria, and order of trigynia; and in the natural system ranking under the 54th order, miscellaneæ. The calyx is pentaphyllous; there are five petals, which are inserted into the receptacle; the capsule is unilocular and trivalvular. There are two species, the imperati and oppositifolium.

TELESCOPE. See OPTICS.

TELLER, an officer of the exchequer, in antient records called tallier; there are four of these officers, whose duty is to receive all sums due to the king, and to give the clerk of the pells a bill to charge him therewith. They likewise pay all money due from the king, by warrant from the auditor of the receipt; and make weekly and yearly books, both of their receipts and payments, which they deliver to the lord treasurer.

TELLINA, a genus of vermes testacea; the generic character is, the animal a tethys; shell bivalve, generally sloping on one side; in the fore-part of one valve a convex, of the other a concave fold; hinge with usually three teeth, the lateral ones smooth in one shell. There are about 100 species, divided into three sections: A ovate and thickish; B ovate and compressed; and C suborbicular. The tellina foliacea is of section B, having the shell oval, with rough pubes, the flattened sides serrate. It inhabits the Indian Ocean and is rare. See Pl. Nat. Hist. fig. 393.

TELLURIUM, a mineral found in Transylvania, which Muller of Reichenstein examined in 1782, and concluded, from his experiments, that the ore, which had been distinguished by the names of aurum problematicum, aurum paradoxicum, and aurum album, contains a new metal different from every other. Being still dissatisfied with his own conclusions, he sent a specimen of it to Bergman; but the specimen was too small to enable that illustrious chemist to decide the point. He ascertained, however, that the metal in question is not antimony. The experiments of Muller appeared so satisfactory, that they induced Mr. Kirwan, in the second edition of his Mineralogy, published in 1796, to give this metal a separate place, under the name of sylvanite. Klaproth published an analysis of the ore in 1798, and completely confirmed the conclusions of Muller. To the new metal, which constitutes 0.925 of the ore, he gave the name of tellurium; and this name has been generally adopted. Gmelin examined the ore in 1799; and his experiments coincide almost exactly with those of Muller and Klaproth. By these philosophers the following properties of tellurium have been ascertained:

Its colour is bluish-white, intermediate between that of zinc and lead; its texture is laminated like antimony; and its brilliancy is considerable. Its hardness has not been ascertained. Its specific gravity, according to Klaproth, is 6.1. It is very brittle, and may be easily reduced to powder. It melts when raised to a temperature somewhat higher than the fusing-point of lead. If the heat is increased a little, it boils and evaporates, and attaches itself in brilliant drops to the upper part of the retort in which the experiment is made. It is therefore, next to mercury and arsenic, the most volatile of all the metals. When cooled slowly, it crystallizes.

When exposed to the action of the blowpipe upon charcoal, it takes fire, and burns with a lively blue flame, the edges of which are green; and is completely volatilized in the form of a white smoke, which, according to Klaproth, has a smell not unlike that of radishes, but which Gmelin could not observe.

This white smoke is the oxide of tellurium, which may be obtained also by dissolving the metal in nitro-muriatic acid, and diluting the the solution with a great quantity of water. A white powder falls to the bottom, which is the oxide. It may be procured also by dissolving the metal in the nitric acid, and adding potass slowly till the oxide precipitates. This oxide is easily melted by heat into a straw-coloured mass of a radiated texture. When made into a paste with oil, and heated in charcoal, it is reduced to the metallic state so rapidly, that a kind of explosion is produced.

Tellurium may be combined with sulphur by fusion. This sulphuret has a leaden grey colour, and a radiated texture; on red-hot coals it burns with a blue flame.

Tellurium may be amalgamated with mercury by trituration. Its other properties have not yet been examined.

TELIFEROUS, in entomology, means such insects as are armed with a dart or sting.

TEMPERAMENT. See PHYSIOLOGY, Vol. II. p. 421.

TEMPERAMENT, in music, the accommodation or adjustment of the imperfect sounds by transferring a part of their defects to the more perfect ones, in order to remedy, in some degree, the false intervals of those instruments, the sounds of which are fixed; as the organ, harpsichord, piano-forte, &c.

Temperament is what the Italians call participatione, participato, or systema temperato, because it is founded on temperature; that is, on the diminution of some intervals and augmentation of others, by which it partakes of the diatonic and chromatic systems.

TEMPERATURE. See METEOROLOGY.

TEMPERING *of steel and iron,* the rendering of them either more compact and hard, or soft and pliant, according as the different uses for which they are wanted may require. See IRON, p. 33. Vol. II.

TEMPLARS, or TEMPLERS, a religious order instituted at Jerusalem, about the year 1118. Some religious gentlemen put themselves under the government of the patriarch of Jerusalem, renounced property, made the vow of celibacy and obedience, and lived like canons regular. King Baldwin assigned them an apartment in his palace. They had likewise lands given them by the king, the patriarch, and the nobility, for their maintenance. They took the name of knights templars, because their first house stood near the temple dedicated to our Saviour, at Jerusalem. This order, after having performed many great exploits against the infidels, became rich and powerful all over Europe; but the knights, abusing their wealth and credit, fell into great disorders and irregularities. Many crimes and enormities being alleged against them, they were prosecuted in France, Italy, and Spain; and at last, the pope, by his bull of the 22nd of May, 1312, given in the council of Vienna, pronounced the extinction of the order of Templars, and united their estates to the order of St. John of Jerusalem.

TEMPORALITIES *of bishops,* are such revenues, lands, and tenements, and lay fees, as have been added to bishops' sees, by kings and other great personages of this land, from time to time, as they are barons and lords of parliament. This revenue of the king, which was antiently very considerable, is now, by a customary indulgence, almost reduced to nothing; for at present, as soon as the new bishop is consecrated and confirmed, he usually receives from the king the restitution of his temporalities entire and untouched; and then and not sooner, he has a fee simple in his bishopric, and may maintain an action for the profits. 1 Black. 283.

TENACITY, a term applied to metals, by which is meant the power that a metallic wire of a given diameter has of resisting, without breaking, the action of a weight suspended from its extremity. Metals differ exceedingly from each other in tenacity. Iron wire, for instance, $\frac{1}{10}$th of an inch in diameter, will support without breaking, about 500lb. weight; whereas one made of lead of the same diameter will not support above 29lb.

TENAILLE. This word literally means shears. A military evolution which was performed in the times of the ancients. In page 206 of Observations on the Military Art, we have the following account of it:

A phalanx, attacked by a lozenge or triangular wedge, bent its right and left forward by a half-quarter conversion, each wing on their common centre; and when they found themselves opposite the sides of the enemy's arrangement, they each marched on their own side, right before them; by which means they both inclosed and attacked the enemy together, at the same time, while the head was engaged and at blows with the centre of the phalanx that had kept its ground. Such is the description authors have left us of the design and effects of this manœuvre.

The tenaille had considerable advantage over the triangular wedge; but, according to chevalier Folard, it was not equally efficacious against the column. The latter could alter the direction of its march, and fall upon one of the wings, whether in motion or not, or detach the section of the tail or rear to take its wings in flank, while it was occupied in making the quarter-conversion. The column and tenaille were formed for acting against each other, and could only be victorious over one another by the superior abilities of their commander. We fancy, however, the column was always exposed to less danger than the tenaille, for the latter could not pursue the column without changing its order; whereas the column must destroy, and in a manner annihilate the tenaille, in case it could once break it.

The tenaille is unquestionably an excellent manœuvre, and strictly conformable to a very wise maxim, which directs us to multiply our strength and efforts as much as possible against one point. We sometimes, indeed, make use of it in war without being sensible of its advantages. This, however, does not hinder the manœuvre from being well performed; for the nature of ground not being level like a sheet of paper, the commander, in ranging his troops, according to the advantages of the situation, does not form a perfect tenaille, such as may be drawn or sketched out, but one of an irregular kind, which produces the same effects; and this is what should be sought on all occasions.

Tenailles, in fortification, are low works made in the ditch before the curtains. There are three sorts; viz. the first are the faces of the bastions produced till they meet, but much lower; the second have faces, flanks, and a curtain; and the third have only faces and flanks.

Tenaille, *single*, a work whose front is advanced towards the country, having two faces, forming a re-entering angle; its two long sides terminate on the counterscarp, opposite to the angle of the shoulder.

Tenaille, *double*, is a work whose front, having four faces, forms two re-entering, and three salient angles; its long sides are likewise parallel, and terminate on the counterscarp, opposite to the angle of the shoulder. Both the single and double tenailles have this fault, viz. that they are not flanked or defended at the re-entering angle, because the height of the parapet hinders the soldiers from discovering before that angle. Therefore tenailles should only be made when there is not room enough to make horn-works. The ramparts, parapets, ditches, covert-way, and glacis of tenailles, are the same with other outworks.

Tenaille *of a place*, is what is comprehended between the points of two neighbouring bastions; as the faces, flanks, and curtains. Hence it is said, the enemy attacked the whole tenaille of a place, when they made two attacks on the faces of the two bastions.

TENANT, signifies one who holds or possesses lands or tenements by any kind of right, either in fee, for life, years, or at will.

TENCH. See Cyprinus.

TENDER, is an offer to pay a debt, or perform a duty. In every plea of tender, where money is the thing demanded by the action, and the debt or duty is not discharged by the tender and refusal, money may be brought in without leave of the court; but as other things as well as money may, where a tender is pleaded, be brought into court; this is with more propriety called bringing into court generally, than a bringing money into court. In all other cases, the leave of the court must be had before money can be brought into court. The rule under which this leave is granted, is, as in the case of an ejectment by a mortgagee, founded upon a particular act of parliament. In other cases, it is founded upon that discretionary power, which is, for the furtherance of justice, vested in the court. By the discretionary rule, it is sometimes ordered, that upon bringing money into court, all proceedings in an action shall be stayed. At other times it is ordered, that the money brought into court shall be struck out of the plaintiff's declaration, and that the plaintiff shall not, at the trial of the issue, be permitted to give any evidence as to this money. This rule, by which the money brought into court is ordered to be struck out of the declaration, is from its being more frequently granted, than that by which it is ordered, that the proceeding shall be stayed, called the common rule. 5 Bac. Abr. 1.

If bank notes have been offered, and no objection made on that account, it has been considered by the court of king's bench as a good tender. 3 Durnf and East, 554.

Tender, a small ship in the service of men of war, for carrying of men, provisions, or any thing else that is necessary.

TENDONS, are white, firm, and tenacious parts, continuous to the muscles, and usually forming their extremities.

TENEBRIO, a genus of insects of the order coleoptera. The generic character is, antennæ moniliform, with the last joint rounded; thorax plano-convex, margined; head exserted; wing-sheaths stiffish. In this genus, of which there are more than 100 species, the body is oblong-oval, and in most species somewhat pointed at the extremity: it may be observed also that several species are destitute of wings. Among the European tenebriones one of the most remarkable is the tenebrio mortisagus, a coal-black insect measuring about an inch in length, of rather slow motion, and distinguished by the remarkably pointed appearance of the wing-sheaths, which at their extremities project a little beyond the abdomen: they are also perfectly connate or undivided, forming a complete covering to the body, being carried over the sides to some distance beneath, and the insect is totally destitute of real or under wings. It is usually found in dark neglected places, beneath boards, in cellars, &c. and if handled, and especially if crushed, diffuses a highly unpleasant smell.

Tenebrio globosus is perhaps not a Linnæan species, unless it is the tenebrio gibbosus of that author. It is seen during the hottest part of the summer about walls and pathways, and is distinguished by the remarkably globular appearance of the body; it is totally black, the under parts having sometimes a slight violaceous cast, and the joints of the feet, which are remarkably broad, are of a dull brown: the whole insect is of a very smooth, but not polished, surface, and usually measures about three quarters of an inch in length: in this however it varies considerably, some specimens, probably the males, being considerably smaller. The antennæ in this insect are beautifully moniliform, all the joints being globular.

Tenebrio molitor is an insect often seen in houses: it is one of the smaller kinds, and is coal-black, of a lengthened shape, with longitudinally striated wing-shells, and proceeds from a larva commonly known by the name of the meal-worm, from its being so frequently found in flour, &c. It is of a yellowish white colour, about an inch long, slender-bodied, and of a highly polished surface, and is considerd as the favorite food of the nightingale when kept in a state of captivity: it is said to remain two years before it changes into a chrysalis.

The genus tenebrio is numerous, and some of the exotic species much resemble the general appearance of the first described, but are much larger. Many others are small insects, and the genus has received, by later discoveries, such accessions, that it has been divided into several distinct genera.

TENEMENT, in its common acceptation, is applied only to houses and other buildings; but in its original, proper, and legal sense, it signifies every thing that may be holden, provided it is of a permanent nature, whether it is of a substantial, or of an unsubstantial and ideal kind. Thus frank tenement, or freehold, is applicable not only to lands and other solid objects, but also to offices, rents, commons, &c. and as lands and houses are tenements, so is an advowson a tenement; and a franchise, or office, a right of common, a peerage, or other property of the like unsubstantial kind, are all of them, legally speaking, tenements. 2 Black. 17.

TENEMENTIS LEGATIS, a writ that lies to London, or any other corporation where the custom is, that men may demise tenements as well as goods and chattels by their last will, for the hearing any controversy touching the same, and for rectifying the wrong.

TENESMUS. See Medicine.

TENNIS, a play at which a ball is driven by a racket. As many persons would become players at tennis, provided they could easily understand the rudiments of the game, so as to form some judgment of the players, or at least to know who wins and who loses, we have here attempted to give so plain a description of it, that no one can be at a loss, if ever he should bet or play. As to the executive part, it requires great practice to make a good player, so that nothing can be done without it; all we presume to do is, to give an insight into the game, by which a person may not seem a total stranger to it when he happens to be in a tennis-court.

The game of tennis is played in most capital cities in Europe, particularly in France, whence we may venture to derive its origin. It is esteemed with many to be one of the most antient games in Christendom, and long before King Charles I.'s time it was played in England.

This game is as intricate as any game whatever; a person who is totally ignorant of it may look on for a month together, without being able to make out how the game is decided. We shall begin therefore by describing the court in which it is played.

The size of a tennis-court is generally about 96 or 97 feet by 33 or 34, there being no exact dimension ascribed to its proportion, a foot more or less in length or width being of no consequence. A line or net hangs exactly across the middle, over which the ball must be struck, either with a racket or board, to make the stroke good. Upon the entrance of a tennis-court, there is a long gallery which goes to the dedans, that is, a kind of front gallery, where spectators usually stand; into which whenever a ball is struck, it tells for a certain stroke. This long gallery is divided into different compartments or galleries, each of which has its particular name, as follows; from the line towards the dedans are the first gallery, door, second gallery, and the last gallery, which is called the service side. From the dedans to the last gallery are the figures 1, 2, 3, 4, 5, 6, at a yard distance each, by which the chaces are marked, and is one of the most essential parts of the game, as will appear in the following description.

On the other side of the line are also the first gallery, door, second gallery, and last gallery, which is called the hazard-side. Every ball struck into the last gallery on this side reckons for a certain stroke the same as the dedans. Between the second and this last gallery are the figures 1, 2, to mark the chaces on the hazard-side. Over this long galler , or these compartments, is a covering, ied the penthouse, on which they play the ll from the service-side, in order to begin a set of tennis, from which it is called a service. When they miss putting the ball (so as to rebound from the penthouse) over a certain line on the service-side, it is deemed a fault, two of which are reckoned for a stroke. If the ball rolls round the penthouse, on the opposite of the court, so as to fall beyond a certain line described for that purpose, it is called passe, reckons for nothing on either side, and the player must serve again.

On the right-hand side of the court from the dedans is what they call the tambour, a part of the wall which projects, and is so contrived in order to make a variety in the stroke, and render it more difficult to be returned by the adversary; for when a ball strikes the tambour, it varies its direction, and requires some extraordinary judgment to return it over the line. The last thing on the right-hand side is called the grill, wherein if the ball is struck, it is also 15, or a certain stroke.

The game of tennis is played by what they call sets; a set of tennis consists of six games: but if they play what is called an advantage-set, two above five games must be won on one side or the other successively, in order to decide; or, if it comes to six games all, two games must still be won on one side to conclude the set; so that an advantage-set may last a considerable time; for which kind of sets the court is paid more than for any other.

We must now describe the use of the chaces, and by what means these chaces decide or interfere so much in the game. When the player gives his service at the beginning of a set, his adversary is supposed to return the ball; and wherever it falls after the first rebound untouched, the chace is called accordingly; for example, if the ball falls at the figure 1, the chace is called at a yard, that is to say, at a yard from the dedans: this chace remains till a second service is given; and if the player on the service-side lets the ball go after his adversary returns it, and if the ball falls on or between any of these figures or chaces, they must change sides, there being two chaces; and he who then will be on the hazard-side, must play to win the first chace; which if he wins by striking the ball so as to fall, after its first rebound, nearer to the dedans than the figure 1, without his adversary's being able to return it from its first hop, he wins a stroke, and then proceeds in like manner to win the second chace, wherever it should happen to be. If a ball falls on the line with the first gallery door, second gallery, or last gallery, the chace is likewise called at such or such a place, naming the gallery-door, &c. When it is just put over the line, it is called a chace at the line. If the player on the service-side returns a ball with such force as to strike the wall on the hazard-side so as to rebound, after the first hop over the line, it is also called a chace at the line.

The chaces on the hazard-side proceed from the ball being returned either too hard or not quite hard enough; so that the ball after its first rebound falls on this side of the blue line, or line which describes the hazard-side chaces; in which case it is a chace at 1, 2, &c. provided there is no chace depending. When they change sides, the player, in order to win this chace, must put the ball over the line any where, so that his adversary does not return it. When there is no chace on the hazard-side, all balls put over the line from the service-side, without being returned, reckon for a stroke.

As the game depends chiefly upon the marking, it will be necessary to explain it, and to recommend those who play at tennis to have a good and unbiassed marker, for on him the whole set may depend: he can mark in favour of the one and against the other in such a manner, as will render it two to one at starting, though even players. Instead of which the marker should be very attentive to the chaces, and not be any way partial to either of the players.

This game is marked in a very singular manner, which makes it at first somewhat difficult to understand. The first stroke is called 15, the second 30, the third 40, and the fourth game, unless the players get four strokes each; in that case, instead of calling it 40 all, it is called deuce; after which, as soon as any stroke is got, it is called advantage; and in case the strokes become equal again, deuce again, till one or the other gets two strokes following, which win the game; and as the games are won, so they are marked and called; as one game love, two games to one, &c. towards the set, of which so many of these games it consists.

Although but one ball at a time is played with, a number of balls are made use of at this game to avoid trouble, and are handed to the players in baskets for that purpose; by which means they can play as long as they please, without ever having occasion to stoop for a ball.

As to the odds at tennis, they are by no means fixed, but are generally laid as follow:

Upon the first stroke being won between even players, that is, fifteen love, the odds are of the single game	7 to	4
Thirty love	4	1
Forty love	8	1
Thirty fifteen	2	1
Forty fifteen	5	1
Forty thirty	3	1
The odds of a four-game set when the first game is won, are	7	4
When two games love	4	1
Three games love	8	1
When two games to one	2	1
Three games to one	5	1
The odds of a six-game set when the first game is won, are	3	2
When two games love	2	1
Three games love	4	1
Four games love	10	1
Five games love	21	1
When two games to one	8	5
Three games to one	5	2
Four games to one	5	1
Five games to one	15	1
When three games to two	7	4
Four games to two	4	1
Five games to two	10	1
When four games to three	2	1
Five games to three	5	1
The odds of an advantage-set when the first game is won, are	5	4
When two games love	7	4
Three games love	3	1
Four games love	5	1
Five games love	15	1
When two games to one	4	3
Three games to one	2	1
Four games to one	7	2
Five games to one	10	1
When three games to two	3	2
Four games to two	3	1
Five games to two	8	1
When four games to three	8	5
Five games to three	3	1
When five games to four	2	1
When six games to five	5	2

The foregoing odds, as beforesaid, are generally laid, but the chaces interfering make the odds very precarious; for example, when there is a chace at half a yard, and a set is five games all, and in every other respect equal, the odds are a good five to four; and if it were six games to five, and forty thirty with the same chace, the odds then would be a guinea to a shilling; so that it is plain that the odds at this game differ from those of any other; for one stroke will reduce a set, supposing the players to be five games all, from an even wager to three to two, and so on in proportion to the stage of the set.

There are various methods of giving odds at tennis, in order to make a match equal; and that they may be understood, we shall give the following list of them, with their meanings, so that any person may form a judgment of the advantage received or given.

The lowest odds that can be given, excepting the choice of the sides, is what they call a bisque, that is, a stroke to be taken or scored whenever the player, who receives the advantage, thinks proper: for instance, suppose a critical game of the set to be forty thirty, by taking the bisque, he who is forty becomes game, and so in respect of two bisques, &c.

The next greater odds are fifteen, that is, a certain stroke given at the beginning of each game.

After these half thirty, that is, fifteen one game, and thirty the next. Then follow the whole thirty, forty, &c.

There are also the following kind of odds which are given, viz.

Round services: those are services given round the penthouse, so as to render it easy for the striker-out (the player who is on the hazard-side) to return the ball.

Half-court, that is, being obliged or confined to play into the adversary's half-court; sometimes it is played straightwise, and at other times across; both which are great advantages given by him so confined, but the straight half-court is the greatest.

Touch-no-wall, that is, being obliged to play within the compass of the walls, or sides of the court. This is a considerable advantage to him who receives it; as all the balls must be played gently, and consequently they are much easier to take than those which are played hard, or according to the usual method of play.

Barring the hazards, that is, barring the dedans, tambour, grill, or the last gallery on the hazard-side, or any particular one or more of them.

These are the common kind of odds or advantages given; but there are many others, which are according to what is agreed by the players; such as playing with board against racket, cricket-bat against racket, &c.

The game of tennis is also played by four persons, two partners on each side. In this case, they are generally confined to their particular quarters, and one of each side appointed to serve and strike out; in every other respect, the game is played in the same manner as when two only play.

Any thing more to be said upon this subject would be needless, as nothing can be recommended, after reading this short account of tennis, but practice and attention, without which no one can become a proficient at the game.

TENON, in building, &c. the square end of a piece of wood, or metal, diminished by one-third of its thickness, to be received into a hole in another place, called a mortise, for jointing or fastening the two together. It is made in various forms, square, dove-tailed, for double mortises, &c.

TENOR, of writs, records, &c. is the substance or purport of them, or a transcript or copy.

Tenor, in music, the second of the four parts in harmonical composition, reckoning from the bass. The tenor is the part most accommodated to the common voice of man; from which circumstance it has sometimes, by way of preference, been called "the human voice." Its general compass extends from C above G gamut to G the treble-cliff note.

The tenor was formerly the plain-song, or principal part in a composition, and derived the name of tenor from the Latin word teneo, I hold; because it held or sustained the air, point, substance, or meaning, of the whole cantus, and every part superadded to it was considered but as its auxiliary. It appears that the contrary practice of giving the air to the soprano, or treble, had its rise in the theatre, and followed the introduction of evirati into musical performances; since which it has been universally adopted both in vocal and instrumental music.

Tenor-cliff, the name given to the C cliff when placed on the fourth line of the stave. See Cliff.

Tenor Violin, or *Viola*, a stringed instrument resembling the violin, but lower in its scale, having its lowest note in C above G gamut. In concert this instrument takes the part next above the bass.

TENSE, *time*, in grammar, an inflection of verbs, whereby they are made to signify or distinguish the circumstance of time, in what they affirm.

TENSION, the state of a thing stretched. Thus animals sustain and move themselves by the tension of their muscles and nerves. A chord or string gives an acuter or deeper sound, as it is in a greater or less degree of tension, that is, more or less stretched or tightened.

TENT, in surgery, a roll of lint worked into the shape of a nail, with a broad flat head. See Surgery.

TENTER, a railing used in the cloth-manufacture, to stretch out the pieces of cloth, stuff, &c. or only to make them even, and set them square. It is usually about four feet and a half high, and for length exceeds that of the longest piece of cloth. It consists of several long pieces of wood, placed so that the lower cross-piece of wood may be raised or lowered, as is found requisite, to be fixed at any height, by means of pins. Along the cross-pieces, both the upper and under one, are hooked nails, called tenter-hooks, driven in from space to space.

TENTHREDO, a genus of insects of the order hymenoptera: the generic character is, mouth with jaws, without proboscis; wings flat, swelled or slightly inflated; piercer consisting of two serrated and scarcely projecting laminæ; scutellum with two distant granules. The larvæ of the genus tenthredo are remarkable for their great resemblance to those of the order lepidoptera or real caterpillars, from which however they may in general be readily distinguished by their more numerous feet, which are never fewer than sixteen, exclusive of the three first or thoracic pairs. When disturbed or handled, they usually roll themselves into a flat spiral. They feed, like the caterpillars of the lepidoptera, on the leaves of plants, and undergo their chrysalis state in a strong gummy case or envelopement, prepared in autumn, out of which in the ensuing spring emerges the complete insect.

The tenthredines form a numerous genus, and may be divided into tribes or sections, according to the form of the antennæ, which are in some clavated, in others filiform, &c. Among the principal species may be numbered the tenthredo lutea of Linnæus, which proceeds from a large green larva, of a finely granulated surface, with a double row of black specks along each side, and a dusky dorsal line bounded on each by yellow: it feeds on various species of willow, &c. The parchment-like case in which it envelops itself in autumn is of a pale yellowish-brown colour, and the chrysalis, which is of a pale dusky or brownish cast, exhibits the limbs of the future fly, which is equal in size to a common wasp, and is of a yellow colour, barred with black: the antennæ rather short, and strongly clavated.

The tenthredo amerinæ of Linnæus is somewhat smaller than the preceding, and of a cinereous-brown colour, with the under part of the abdomen rufous or dull orange: like the former, its caterpillar is of a green colour, and of a finely roughened surface powdered with numerous whitish specks.

The larvæ of the smaller tenthredines are often very injurious to different kinds of esculent vegetables, as turnips, &c. &c. There are nearly 200 species of this insect.

TENTHS, that yearly portion or tribute which all ecclesiastical livings antiently paid to the king. See First Fruits.

TENURE, the manner whereby lands or tenements are holden, or the service that the tenant owes to his lord. Under the word tenure is included every holding of an inheritance; but the signification of this word, which is a very extensive one, is usually restrained by coupling other words with it: this is sometimes done by words which denote the duration of the tenant's estate; as if a man holds to himself and his heirs, it is called tenure in fee-simple. At other times the tenure is coupled with words pointing out the instrument by which an inheritance is held: thus, if the holding is by copy of court-roll, it is called tenure by copy of court-roll. At other times, this word is coupled with others that shew the principal service by which an inheritance is held: as where a man held by knight's service, it is called tenure by knight's service. 5 Bac. Abr. 34.

TERAMNUS, a genus of the diadelphia decandria class and order of plants: the keel is very small, concealed within the calyx; stamina alternate, five, barren; stigma sessile, headed. There are two species, creeping plants of Jamaica.

TEREBELLA, a genus of vermes mollusca. The generic character is, body oblong, creeping, naked, often enclosed in a tube furnished with lateral tufts and branchiæ; mouth placed before, furnished with lips, without teeth, and protending a clavate proboscis; feelers numerous, ciliate, capillary, seated round the mouth. There are eleven species.

TEREDO, in natural history, a genus of vermes belonging to the order of testacea. The animal is a terebella; there are two valves, calcareous, hemispherical, and cut off before, and two lanceolated. The shell is tapering, bending, and capable of penetrating wood. There are only three species, the navalis, utriculis, and clava. See Plate Nat. Hist. fig. 394.

The navalis, or ship-worm, which has a very slender smooth cylindrical shell, inhabits the Indian seas, whence it was imported into Europe. It penetrates easily into the stoutest oak-planks, and produces dreadful destruction to the ships by the holes it makes in their sides; and it is to avoid the effects of this insect that vessels require sheathing.

The head of this creature is well prepared by nature for the hard offices which it has to undergo, being coated with a strong armour, and furnished with a mouth like that of the leech, by which it pierces wood as that animal does the skin. A little above this it has two horns which seem a kind of continuation of the shell; the neck is as strongly provided for the service of the creature as the head, being furnished with several strong muscles; the rest of the body is only covered by a very thin and transparent skin, through which the motion of the intestines is plainly seen by the naked eye; and by means of the microscope several other very remarkable particulars become visible there. This creature is wonderfully minute when newly excluded from the egg; but it grows to the length of four or six inches, and sometimes more.

When the bottom of a vessel, or any piece of wood which is constantly under water, is inhabited by these worms, it is full of small holes; but no damage appears till the outer parts are cut away: then their shelly habitations come into view; in which there is a large space for inclosing the animal, and surrounding it with water. There is an evident care in these creatures never to injure one another's habitations, by which means each case or shell is preserved entire; and in such pieces of wood as have been found eaten by them into a sort of honeycomb, there never is seen a passage or communication between any two of the shells, though the woody matter between them often is not thicker than a piece of writing-paper. They penetrate some kinds of wood more easily than others.

They make their way most quickly into fir and alder, and grow to the greatest size. In the oak they make small progress, and appear small and feeble, and their shells much discoloured.

Since each of these animals is lodged in a solitary cell, and has no access to those of its own species, it has been matter of surprise how they should increase to so vast a multitude. Upon dissecting them, it appears that every individual has the parts of both sexes, and is therefore supposed to propagate by itself.

The sea-worms, which are pernicious to our shipping, appear to have the same office allotted to them in the waters which the termites have on the land (see TERMES). They will appear, on a very little consideration, to be most important beings in the great chain of creation, and pleasing demonstrations of that infinitely wise and gracious Power which formed, and still preserves, the whole in such wonderful order and beauty; for if it was not for the rapacity of these and such animals, tropical rivers, and indeed the ocean itself, would be choked with the bodies of trees which are annually carried down by the rapid torrents, as many of them would last for ages, and probably be productive of evils, of which, happily, we cannot in the present harmonious state of things form any idea; whereas now being consumed by these animals, they are more easily broken in pieces by the waves; and the fragments which are not devoured become specifically lighter, and are consequently more readily and more effectually thrown on shore, where the sun, wind, insects, and various other instruments, speedily promote their entire dissolution.

TERES. See ANATOMY.

TERM, in geometry, is the extreme of any magnitude, or that which bounds and limits its extent. So the terms of a line, are points; of a superficies, lines; of a solid, superficies.

TERMS, of an equation, or of any quantity, in Algebra, are the several names or members of which it is composed, separated from one another by the signs + or —. So, the quantity $ax + 2bc - 3ax^2$, consists of the three terms ax and $2bc$ and $3ax^2$.

In an equation, the terms are the parts which contain the several powers of the same unknown letter or quantity: for if the same unknown quantity is found in several members in the same degree or power, they shall pass but for one term, which is called a compound one, in distinction from a simple or single term. Thus, in the equation $x^3 + \overline{a - 3b} . x^2 - acx = b^3$ the four terms are x^3 and $\overline{a - 3b} . x^2$ and acx and b^3; of which the second term $\overline{a - 3b} . x^2$ is compound, and the other three are simple terms.

TERMS of a product, or of a fraction, or of a ratio, or of a proportion, &c. are the several quantities employed in forming or composing them. Thus, the terms

of the product ab, are a and b;
of the fraction $\frac{5}{8}$, are 5 and 8;
of the ratio 6 to 7, are 6 and 7;
of the proportion $a : b :: 5 : 9$, are a, b, 5, 9.

TERMS, are those spaces of time wherein the courts of justice are open for all that complain of wrongs or injuries, and seek their rights by course of law or action, in order to their redress; and during which, the courts in Westminster-hall sit and give judgments, &c. but the high court of parliament, the chancery, and inferior courts, do not observe the terms; only the courts of king's-bench, common-pleas, and exchequer, the highest courts at common law. Of these terms there are four in every year, viz. Hilary term, which begins the 23d of January, and ends the 12th of February, unless on Sundays, and then the day after; Easter term, which begins the Wednesday fortnight after Easter-day, and ends the Monday next after ascension-day; Trinity term, which begins the Friday after Trinity Sunday, and ends the Wednesday fortnight after; and Michaelmas term begins the 6th and ends the 28th of November.

There are in each of these terms stated days, called days in bank, that is, days of appearance in the court of common pleas, called usually bancum, or commune bancum, to distinguish it from bancum regis, or the court of king's-bench. They are generally at the distance of about a week from each other, and regulated by some festival of the church. On some of these days in bank, all original writs must be made returnable, and therefore they are generally called the returns of that term. 3 Black. 227.

The first return in every term is, properly speaking, the first day in that term; and thereon the court sits to take essoins, or excuses, for such as do not appear, according to the summons of this writ; wherefore this is usually called the essoin day of the term. But the person summoned has three days grace beyond the return of the writ, in which to make his appearance; and if he appears on the fourth day inclusive, quarto die post, it is sufficient. Therefore, at the beginning of each term, the court does not sit for dispatch of business till the fourth day, and in Trinity term, by stat. 32 H. VIII. c. 21, not till the sixth day. 3 Black. 227.

TERMS, *Oxford*. Hilary, or Lent term, begins on Jan. 14, and ends the Saturday before Palm Sunday. Easter term begins the tenth day after Easter, and ends the Thursday before Whit-Sunday. Trinity term begins the Wednesday after Trinity Sunday, and ends after the act, sooner or later, as the vice-chancellor and convocation please. Michaelmas term begins on Oct. 10, and ends Dec. 17.

TERMS, *Cambridge*. Lent term begins on Jan. 13, and ends the Friday before Palm Sunday. Easter term begins the Wednesday after Easter week, and ends the week before Whit Sunday. Trinity term begins the Wednesday after Trinity Sunday, and ends the Friday after the commencement. Michaelmas term begins Oct. 10, and ends Dec. 16.

TERMS, *Scottish*. In Scotland Candlemas term begins Jan. 23, and ends Feb. 12. Whitsuntide term begins May 25, and ends June 15. Lammas term begins July 20, and ends Aug. 8. Martinmas term begins Nov. 3, and ends Nov. 29.

TERMES, *the white ant*, a genus of insects of the order aptera: the generic character is, legs six, formed for running; eyes two; antennæ setaceous; mouth furnished with two jaws. The European species of termes are very small, compared with those of the warmer regions of Africa and America; and instead of assembling in multitudes, as in those climates, are usually observed single. The most common of these is the termes pulsatorius of Linnæus, a diminutive insect, of a whitish colour, and which, from its general resemblance to the insects of that genus, has by Derham and some other naturalists been distinguished by the title of pediculus pulsatorius. It is very frequent, during the summer months, in houses, particularly where the wainscot is in any degree decayed, and is remarkable for causing a long-continued sound, exactly resembling the ticking of a watch. It is a very common insect in collections of dried plants, &c. which it often injures greatly. It is of so tender a frame as to be easily destroyed by the slightest pressure, and is an animal of very quick motion. When magnified, the head appears large; the eyes remarkably conspicuous, of a most beautiful gold-colour, and divided, like those of most other insects, into innumerable hexagonal convexities; the antennæ long and setaceous; the palpi or feelers two in number, of moderate length, and terminating in a large club-shaped tip; the thorax rather narrow, and the abdomen obtusely oval; the thighs or first joints of the legs thick, the remaining ones slender, and the feet furnished with very small claws: the whole animal is beset with small, scattered hairs. According to the observations of the celebrated Derham, this insect, at its first hatching from the egg, which is white, oval, and extremely small, bears a complete resemblance to a common mite, being furnished with eight legs, and beset with long hairs. After a certain time it casts its skin, and appears in the very different form above-described. Some individuals of this species become winged when arrived at their full growth; the wings, which are four in number, being very large, of a slightly iridescent appearance, and variegated with blackish and brown clouds or spots. It is in the beginning of July that this change takes place, and at this time several may be seen with the wings half-grown; in a few days they seem to obtain their full size.

Mr. Derham imagines the ticking sound which these animals produce, to be analogous to the call of birds to their mates during the breeding-season; and there seems to be no reason for calling in question the truth of this observation. We may add, that this sound, as well as that produced by the ptinus fatidicus, or death-watch, seems to afford a convincing proof of the faculty of hearing in insects, which some naturalists have been inclined to deny.

Of the exotic termites the most remarkable seems to be the termes bellicosus, whose history is described by Mr. Smeathman in the Philosophical Transactions.

With the good order of their subterraneous cities, they will appear foremost on the list of the wonders of the creation, as most closely imitating mankind in provident industry and regular government.

The termites are represented by Linnæus as the greatest plagues of both Indies, and are indeed every way between the tropics so deemed. These insects have generally obtained the names of ants, it may be presumed, rom the similarity in their manner of living, which is in large communities that erect very extraordinary nests, for the most part on the surface of the ground, whence their excursions are made through subterraneous passages or covered galleries, which they build whenever necessity obliges, or plunder induces, them to march above ground; and at a great distance from their habitations carry on a business of depredation and destruction, scarcely credible but to those who have seen it.

The termites resemble the ants also in their provident and diligent labour, but surpass them as well as the bees, wasps, beavers, and all other animals, in the arts of building, as much as the Europeans excel the least cultivated savages. It is more than probable they excel them as much in sagacity and the arts of government; it is certain they shew more substantial instances of their ingenuity and industry than any other animals; and do in fact lay up vast magazines of provisions and other stores; a degree of prudence which has of late years been denied, perhaps without reason, to the ants.

Their communities consist of one male and one female (who are generally the common parents of the whole, or greater part, of the rest); and of three order of insects, apparently of very different species, but really the same, which together compose great commonwealths, or rather monarchies, if we may be allowed the term.

The different species of this genus resemble each other in form, in their manner of living, and in their good and bad qualities, but differ as much as birds in the manner of building their habitations or nests, and in the choice of the materials of which they compose them.

There are some species which build upon the surface of the ground, or part above and part beneath; and one or two species, perhaps more, that build on the stems or branches of trees, sometimes aloft at a vast height.

Of every species there are three orders; first, the working insects, which, for brevity, we shall generally call labourers; next the fighting ones, or soldiers, which do no kind of labour; and, last of all, the winged ones, or perfect insects, which are male and female, and capable of propagation.

The nests of the termes bellicosus are so numerous all over the island of Bananas, and the adjacent continent of Africa, that it is scarcely possible to stand upon any open place, such as a rice-plantation, or other clear spot, where one of these buildings is not to be seen within fifty paces, and frequently two or three are to be seen almost close to each other. In some parts near Senegal, as mentioned by Mons. Adanson, their number, magnitude, and closeness of situation, make them appear like the villages of the natives.

These buildings are usually termed hills, by natives as well as strangers, from their outward appearance, which is that of little hills more or less conical, generally pretty much in the form of sugar-loaves, and about ten or twelve feet in perpendicular height above the common surface of the ground.

These hills continue quite bare until they are six or eight feet high; but in time the dead barren clay, of which they are composed, becomes fertilized by the genial power of the elements in these prolific climates, and the addition of vegetable and other matters brought by the wind; and in the second or third year, the hillock, if not over-shaded by trees, becomes, like the rest of the earth, almost covered with grass and other plants; and in the dry season, when the herbage is burnt up by the rays of the sun, it is not much unlike a very large hay-cock.

Every one of these buildings consists of two distinct parts, the exterior and the interior. The exterior is one large shell in the manner of a dome, large and strong enough to inclose and shelter the interior from the vicissitudes of the weather, and the inhabitants from the attacks of natural or accidental enemies. It is always, therefore, much stronger than the interior building, which is the habitable part, divided with a wonderful kind of regularity and contrivance into an amazing number of apartments for the residence of the king and queen, and the nursing of their numerous progeny; or for magazines, which are always found well filled with stores and provisions.

From these habitations, galleries again ascend, and lead out horizontally on every side, and are carried under ground near to the surface a vast distance: for if you destroy all the nests within one hundred yards of your house, the inhabitants of those which are left unmolested farther off, will nevertheless carry on their subterraneous galleries, and invade the goods and merchandizes contained in it by sap and mine, and do great mischief if you are not very circumspect.

It has been observed, that there are of every species of termites three orders; of these orders the working insects or labourers are always the most numerous; in the termes bellicosus there seems to be at the least one hundred labourers to one of the fighting insects or soldiers. They are in this state about one-fourth of an inch long, and twenty-five of them weigh about a grain; so that they are not so large as some of our ants. The second order, or soldiers, have a very different form from the labourers, and have been by some authors supposed to be the males, and the former neuters; but they are, in fact, the same insects, only they have undergone a change of form, and approached one degree nearer to the perfect state. They are now much larger, being half an inch long, and equal in bulk to fifteen of the labourers. There is now likewise a most remarkable circumstance in the form of the head and mouth; for in the former state the mouth is evidently calculated for gnawing and holding bodies; but in this state, the jaws being shaped just like two very sharp awls, a little jagged, they are incapable of any thing but piercing or wounding, for which purposes they are very effectual, being as hard as a crab's claw, and placed in a strong horny head, which is of a nut-brown colour, and larger than all the rest of the body together, which seems to labour under great difficulty in carrying it; on which account perhaps the animal is incapable of climbing up perpendicular surfaces. The third order, or the insect in its perfect state, varies its form still more than ever. The head, thorax, and abdomen, differ almost entirely from the same parts in the labourers and soldiers; and, besides this, the animal is now furnished with four fine large brownish, transparent, wings, with which it is at the time of emigration to wing its way in search of a new settlement. We may open twenty nests without finding one winged insect, for those are to be found only just before the commencement of the rainy season, when they undergo the last change, which is preparative to their colonization.

In the winged state they have also much altered their size as well as form. Their bodies now measure between six and seven tenths of an inch in length, and their wings above two inches and a half from tip to tip, and they are equal in bulk to about thirty labourers, or two soldiers. They are now also furnished with two large eyes placed on each side of the head, and very conspicuous: if they have any before, they are not easily to be distinguished. Probably in the two first states, their eyes, if they have any, may be small, like those of moles: for as they live, like these animals, always under ground, they have as little occasion for these organs, and it is not to be wondered at that we do not discover them; but the case is much altered when they arrive at the winged state in which they are to roam, though but for a few hours, through the wide air, and explore new and distant regions. In this form the animal comes abroad during, or soon after, the first tornado, which, at the latter end of the dry season, proclaims the approach of the ensuing rains, and seldom waits for a second or third shower, if the first, as is generally the case, happens in the night, and brings much wet after it.

The quantities that are to be found the next morning all over the surface of the earth, but particularly on the waters, are astonishing; for their wings are only calculated to carry them a few hours, and after the rising of the sun not one in a thousand is to be found with four wings, unless the morning continues rainy, when here and there a solitary being is seen winging its way from one place to another, as if solicitous only to avoid its numerous enemies, particularly various species of ants which are hunting on every spray, on every leaf, and in every possible place, for this unhappy race, of which probably not a pair in many millions get into a place of safety, fulfil the first law of nature, and lay the foundation of a new community.

The termites arborum, those which build in trees, frequently establish their nests within the roofs and other parts of houses, to which they do considerable damage, if not timely extirpated. The large species are not only much the most destructive, but more difficult to be guarded against, since they make their approaches chiefly under ground, descending below the foundations of houses and stores at several feet from the surface, and rising again either in the floors, or entering at the bottoms of the posts, of which the sides of the buildings are composed, bore quite through them, following the course of the fibres to the top, or making lateral perforations and cavities here and there as they proceed.

While some are employed in gutting the posts, others ascend from them, entering a rafter or some other part of the roof. If they once find the thatch, which seems to be a favourite food, they soon bring up wet clay, and build their pipes or galleries through the roof in various directions, as long as it will support them; sometimes eating the palm-tree leaves and branches of which it is composed, and, perhaps (for variety seems very pleasing to them) the rattan, or other running plant, which is used as a cord to tie the various parts of the roof together, and that to the posts which support it; thus, with the assistance of the rats, who during the rainy season are apt to shelter themselves there, and to burrow through it, they very soon ruin the house by weakening the fastenings, and exposing it to the wet. In the mean time the posts will be perforated in every direction, as full of holes as that timber in the bottoms of ships which has been bored by the worms; the fibres and knotty parts, which are the hardest, being left to the last.

They sometimes, in carrying on this business, seem to find that the post has some weight to support, and then if it is a convenient track to the roof, or is itself a kind of wood agreeable to them, they bring their mortar, and fill all or most of the cavities, leaving the necessary roads through it, and as fast as they take away the wood, replace the vacancy with that material; which being worked together by them closer and more compactly than human strength or art could ram it, when the house is pulled to pieces, in order to examine if any of the posts are fit to be used again, those of the softer kinds are often reduced almost to a shell, and all or a greater part transformed from wood to clay, as solid and as hard as many kinds of free-stone used for building in England. It is much the same when the termites bellicosi get into a chest or trunk containing clothes and other things; if the weight above is great, or they are afraid of ants or other enemies, and have time, they carry their pipes through, and replace a great part with clay, running their galleries in various directions. The tree termites indeed, when they get within a box, often make a nest there, and being once in possession, destroy it at their leisure.

When the termites attack trees and branches in the open air, they sometimes vary their manner of doing it. If a stake in a hedge has not taken root and vegetated, it becomes their business to destroy it. If it has a good sound bark round it, they will enter at the bottom, and eat all but the bark, which will remain, and exhibit the appearance of a solid stick (which some vagrant colony of ants or other insects often shelter in till the winds disperse it); but if they cannot trust the bark, they cover the whole stick with their mortar, and then it looks as if it had been dipped into thick mud that had been dried on. Under this covering they work, leaving no more of the stick and bark than is barely sufficient to support it, and frequently not the smallest particle; so that upon a very small tap with your walking-stick, the whole stake, though apparently as thick as your arm, and five or six feet long, loses its form, and disappearing like a shadow, falls in small fragments at your feet.

The first object of admiration which strikes one upon opening their hills, is the behaviour of the soldiers. If you make a breach in a slight part of the building, and do it quickly with a strong hoe, or pick-axe, in the space of a few seconds a soldier will run out, and walk about the breach, as if to see whether the enemy is gone, or to examine what is the cause of the attack. He will sometimes go again, as if to give the alarm; but most frequently, in a short time, is followed by a large body, who rush out as fast as the breach will permit them; and so they proceed, the number increasing, as long as any one continues battering their building. It is not easy to describe the rage and fury they shew. In their hurry they frequently miss their hold, and tumble down the sides of the hill, but recover themselves as quickly as possible; and, being blind, bite every thing they run against, and thus make a crackling noise, while some of them beat repeatedly with their forceps upon the building, and make a small vibrating noise, something shriller and quicker than the ticking of a watch. If they get hold of any one, they will in an instant let out blood enough to weigh against their whole body; and if it is the leg they wound, you will see the stain upon the stocking extend an inch in width. They make their hooked jaws meet at the first stroke, and never quit their hold, but suffer themselves to be pulled away leg by leg, and piece after piece, without the least attempt to escape. On the other hand, keep out of their way, and give them no interruption, and they will in less than half an hour retire into the nest, as if they supposed the wonderful monster that damaged their castle to be gone beyond their reach. Before they are all got in you will see the labourers in motion, and hastening in various directions toward the breach, every one with a burthen of mortar in his mouth ready-tempered. This they stick upon the breach as fast as they come up, and do it with so much dispatch and facility, that although there are thousands, or rather millions, of them, they never stop or embarrass one another; and you are most agreeably deceived, when, after an apparent scene of hurry and confusion, a regular wall arises, gradually filling up the chasm. While they are thus employed, almost all the soldiers are retired quite out of sight.

A renewal of the attack, however, instantly changes the scene. At every stroke we hear a loud hiss; and on the first the labourers run into the many pipes and galleries with which the building is perforated, which they do so quickly that they seem to vanish, for in a few seconds all are gone, and the soldiers rush out as numerous and as vindictive as before.

Previously to breeding, a very surprising change takes place in the body of the queen or breeding animal. The abdomen of this female, in the termes bellicosus especially, begins gradually to extend and enlarge to such an enormous size, that an old queen will have it increased so as to be fifteen hundred or two thousand times the bulk of the rest of her body, and twenty or thirty thousand times the bulk of a labourer. Mr. Smeethman conjectures the animal is upwards of two years old when the abdomen is increased to three inches in length, and has sometimes found them of near twice that size. The abdomen is now of an irregular oblong shape, being contracted by the muscles of every segment, and is become one vast matrix full of eggs, which make long circumvolutions through an innumerable quantity of very minute vessels that circulate round the inside in a serpentine manner, which would exercise the ingenuity of a skilful anatomist to dissect and develope. This singular matrix is not more remarkable for its amazing extension and size, than for its peristaltic motion, which resembles the undulating of waves, and continues incessantly without any apparent effort of the animal; so that one part or other alternately is rising and sinking in perpetual succession, and the matrix seems never at rest, but is always protruding eggs to the amount of sixty in a minute, or eighty thousand and upward in one day of twenty-four hours. These eggs are instantly taken from her body by her attendants (of whom there are always, in the royal chamber and the galleries adjacent, a sufficient number in waiting) and carried to the nurseries, which in a great nest may some of them be four or five feet distant in a straight line, and consequently much farther by their winding galleries. Here, after they are hatched, the young are attended and provided with every thing necessary until they are able to shift for themselves, and take their share of labour.

TERMINALIA, a genus of plants of the class of polygamia, and order of monœcia. The male calyx is quinquepartite; there is no corolla; the stamina are ten in number. The hermaphrodite flower is the same with that of the male; there is one style; the fruit, which is a drupe or plum, is below, and shaped like a boat. There are six species.

TERMINATOR, in astronomy, a name sometimes given to the circle of illumination, from its property of terminating the boundaries of light and darkness.

TERNSTROEMIA, a genus of the class and order polyandria monogynia. The calyx is five-parted; the corolla one-petalled, wheel-shaped; anthers thick at the top; berry two-celled. There are five species, trees of the East and West Indies.

TERRA PONDEROSA. See Barytes.

TERRÆ FILIUS, *son of the earth*, a student of the university of Oxford, formerly appointed, in public acts, to make jesting and satyrical speeches against the members thereof to tax them with any growing corruptions, &c.

TERRE-PLEIN, or Terre-plain, in fortification, the top, platform, or horizontal surface, of the rampart, upon which the cannon are placed, and where the defenders perform their office. It is so called because it lies level, having only a little slope outwardly to counteract the recoil of the cannon. Its breadth is from 24 to 30 feet; being terminated by the parapet on the outer side, and inwardly by the inner talus.

TERRELLA, or little earth, is a magnet turned of a spherical figure, and placed so that its poles, equator, &c. do exactly correspond with those of the world. It was so first called by Gilbert, as being a just representation of the great magnetic globe we inhabit. Such a terrella, it was supposed, if nicely poised, and hung in a meridian like a globe, would be turned round like the earth in 24 hours by the magnetic particles pervading it; but experience has shewn that this is a mistake.

TERRIER, a book or roll, wherein the several lands, either of a private person, or of a town, college, church, &c. are described. It should contain the number of acres, and the site, boundaries, tenant's names, &c. of each piece or parcel.

TESSELLATED PAVEMENTS, those of rich mosaic work, made of curious square marbles, bricks, or tiles, called tesselæ from their resembling dice.

TEST, a vessel used in metallurgy for absorbing the scoriæ of metallic bodies when melted. See Cupellation, Chemistry, and Metallurgy. Some of the German writers recommend, both for tests and cupels, a sort of friable opake stone, called white spath, which appears to be a species of gypsum, or of the stones from which plaister of Paris is prepared. The spath is directed to be calcined with a gentle fire, in a covered vessel, till the slight crackling, which happens at first, has ceased, and the stone has fallen in part into powder: the whole is then reduced into subtle powder, which is passed through a fine sieve, and moistened with so much of a weak solution of green vitriol as is sufficient for making it hold together. Gellert, however, finds, that if the stone is of the proper kind, which can be known only by trials, calcination is not necessary. Scheffer observes, that these kind of tests are liable to soften or fall asunder in the fire, and that this inconvenience may be remedied by mixing with the uncalcined stone somewhat less than equal its weight, as eight-ninths, of such as has been already used and is penetrated by the scoria of the lead, taking only that part of the old test which appears of a green-grey colour, and rejecting the red crust on the top. Tests or cupels made of the spath are said not to require so much caution in nealing and heating them as the common ones; it appears, however, from Scheffer's account, that they are less durable than those made of the ashes of bones, though greatly superior to those of wood-ashes. Vegetable ashes, which stand pretty well the testing of silver, can scarcely bear any great quantity of gold, this metal requiring a considerably stronger fire than the other; but bone-ashes answer so effectually, and are among us so easily procurable, that it is not needful for the refiner to search for any other materials; though those who work off large quantities of lead, in order to gain a little silver or gold contained in it, may possibly, in places remote from populous cities, avail themselves of substances similar to the spath above mentioned.

The test, for its greater security, is fixed in the mould in which it was formed; which is sometimes a shallow vessel made of crucible-earth or cast iron; more commonly an iron hoop, with three bars arched downwards across the bottom, about two inches deep, and of different widths, from three or four inches to fifteen or more, according to the quantity of metal to be tested at once. The ashes or earthy powder, moistened as for making cupels, are pressed down in the mould so as to completely fill it, or rise a little above the sides; with care to make the mass equally solid, and to put in at once, or at least after the bottom has been pressed close, as much of the matter as will be sufficient for the whole; for any additional quantity will not unite thoroughly with the rest, but be apt to part from it in the fire. The edges are pared smooth, and a portion cut out from the middle with a bent knife, so as to leave a proper cavity; which is smoothed by strewing some dry powder on the surface, and rolling on it a wooden, or rather a glass ball.

The process of testing is often performed in the same manner as that of cupellation: but where great quantities of base metal are to be worked off from a little gold, recourse is had to a more expeditious method, that of testing before the bellows.

An oval test is placed in a cavity, made in a hearth of a convenient height, and some moistened sand or ashes pressed round it to keep it steady: the nose of a bellows is directed along its surface, in such a manner, that if ashes are sprinkled in the cavity of the test, the bellows may blow them completely out: some have an iron plate fixed before the bellows, to direct the blast downwards. To keep the surface of the test from being injured in putting in the metal, some cloths or pieces of paper are interposed. The fuel consists of billets of barked oak laid on the sides of the test, with others laid crosswise on these: the bellows impel the flame on the metal, clear the surface of ashes or sparks of coal, hasten the scorification of the lead, and blow off the scoria, as fast as it forms, to one end of the test, where it runs out through a notch made for that purpose. About two-thirds of the scorified lead may thus be collected; the rest being partly absorbed by the test, and partly dissipated by the action of the bellows. Care must be taken not to urge the blast too strongly, lest some portion of the gold should be carried away by the fumes impetuously forced off from the lead, and some minute particles of it entangled and blown off with the scoriæ.

Test-act, a statute 25 Car. II. cap. 2. which requires all officers, both civil and military, to take the oaths and test, viz. the sacrament, according to the rites and ceremonies of the church of England; for the neglect whereof, a person executing any office, mentioned in that statute, forfeits the sum of 500*l*. recoverable by action of debt.

TESTACEA, in the Linnæan system of natural history, the third order of vermes. This order comprehends all shell-fish, arranged by Linnæus under thirty-six genera. Shell-fish are animals with a soft body, covered by or inclosed in a firm, hard, and stony habitation, composed, according to their three separate orders, 1. Of many parts which are ranged under the name of multivalves; 2. Of two parts, which are called bivalves; 3. Of one part or piece only, which we call univalves. These parts, pieces, or valves, are more or less moveable at the animal's pleasure. The animals included in these hard habitations have most of them the characters of one or other of the genera vermium, and might be reduced under the same genera with the mollusca: but as these characters are few, and the shells very numerous, and different in their form and structure, it will tend more to make this part of natural history easy, to arrange the subjects according to the distinctions of the shells themselves. There is this farther consideration in favour of this arrangement, viz. that the animals themselves are rarely seen, and never can be preserved in cabinets; whereas the shells make a figure in them, and great numbers have been met with empty of the animal. The genera classed under the several divisions of this order are,

A. Multivalves; chiton, lepas, phloas. B. Bivalves; mya, solen, tellina, cardium mactra, donax, venus, spondylus, chama, arca, ostrea, anomia, mytillus, pinna. C. Univalves with a regular spire; argonauta, nautilus, conus, cypræa, bulla, voluta, buccinum, strombus, murex, trochus, turbo, helix, nerita, haliotis. D. Univalves without a regular spire; patella, dentalium, serpula, teredo, sabella.

TESTAMENT, in law, a solemn and authentic act, whereby a person declares his will, as to the disposal of his estate, effects, burial, &c. See Will.

TESTATUM, in law, a writ in personal actions, where, if the defendant cannot be arrested on a capias, in the county where the action is laid, but is returned non est inventus by the sheriff, this writ shall be sent into any other county, where such person is thought to be, or have wherewithal to satisfy the demand. It is called testatum, because the sheriff has, before, testified that the defendant was not to be found in his bailiwick.

TESTE, in law, a word generally used in the conclusion of every writ, wherein the date is contained, and begins with teste meipso, &c. in case it is an original writ; or, if only judical, then with teste, naming the chief justice of the bench whence the writ issues.

TESTES. See Anatomy.

TESTUDO, tortoise, a genus of amphibia, of the order reptiles. The generic character is, body defended by a bony covering coated by a horny, scaly, or coriaceous integument; mouth without distinct or proper teeth, the upper mandible closing over the lower.

In no branch of natural history have more errors prevailed than in the attempt to discriminate with precision the several species of tortoises; the general similarity being very great, and the individuals occasionally varying much in size, colours, &c. according to the different periods of their growth. On the whole, the animals are best distinguished by the shape, pattern, and colours of the shell, the form of the head, &c. There are 35 species, of which the most remarkable are:

Of land and fresh-water tortoises.

1. Testudo græca, common tortoise. The common or Greek tortoise is supposed to be a native of almost all the countries bordering on the Mediterranean sea; and is thought to be more frequent in Greece than in other regions. It is found in the scattered European islands of the Archipelago, and in Corsica and Sardinia. It occurs likewise in many parts of Africa. In Greece, according to Forskal, "it forms an article of food; and the inhabitants often swallow the blood recent, and eat the eggs boiled, which are about the size of those of a pigeon, four or five in number, and of a white colour. In September the animal hides itself under ground, and again emerges in February; laying its eggs in June, in a small hole, which it scratches in some sunny spot, out of which, after the first rains of September, the young are hatched, which are about the size of a walnut. The males of this species are said to fight often, butting at each other with such force as to be heard at a considerable distance."

The general length of the shell of this species is from six to eight inches, which latter measure it rarely exceeds: the weight of the full-grown animal is about forty-eight ounces. The shell is of an oval form, extremely convex on the upper part, and composed, as in most others, of thirteen middle pieces, and about twenty-five marginal ones. The head is rather small than large; the eyes small and black; the mouth not extending beyond the eyes; the upper part of the head covered with somewhat irregular, tough scales, and the neck with smaller granulations, so as to be flexible at the pleasure of the animal. The legs are short, and the feet moderately broad, covered with strong ovate scales, and commonly furnished with four moderately stout claws on each; but this is a circumstance which cannot be allowed to constitute a part of the specific character, since in different individuals, either from age, or other circumstances, these parts are found to vary in number, there being sometimes five claws instead of four on the fore feet. The tail is about the same length with the legs, or rather shorter, and is covered with small scales, and terminates in a naked horny pointed tip or process.

This animal lives to a most extraordinary age; several well attested examples being adduced of its having considerably exceeded the period of a century. One of the most remarkable instances is that of a tortoise introduced into the archiepiscopal garden at Lambeth, in the time of archbishop Laud, and as near as can be collected from its history, about the year 1633, which continued to live there till the year 1753, when it was supposed to have perished rather from accidental neglect on the part of the gardener, than from the mere effect of age. This tortoise has had the honour of being commemorated by Derham, and many other writers, and its shell is preserved in the library of the palace at Lambeth.

The general manners of the tortoise, in a state of domestication in this country, are very agreeably detailed by Mr. White, in his history of Selbourn. "A land-tortoise," says Mr. White, "which has been kept thirty years in a little walled court, retires under ground about the middle of November, and comes forth again about the middle of April. When it first appears in the spring, it discovers very little inclination for food, but in the height of summer grows voracious; and then, as the summer declines, its appetite declines; so that for the last weeks in autumn it hardly eats at all. Milky plants, such as lettuces, dandelions, sowthistles, &c. are its principal food. On the first of November, 1771, I remarked that the tortoise began to dig the ground, in order to form its hybernaculum, which it had fixed on just beside a great tuft of hepaticas. It scrapes out the ground with its fore feet, and throws it up over its back with its hind, but the motion of its legs is ridiculously slow, little exceeding the hour-hand of a clock. Nothing can be more assiduous than this creature, night and day, in scooping the earth, and forcing its great body into the cavity; but as the noons of that season proved unusually warm and sunny, it was continually interrupted, and called forth by the heat in the middle of the day; and though I continued there till the thirteenth of November, yet the work remained unfinished. Harsher weather, and frosty mornings, would have quickened its operations. No part of its behaviour ever struck me more than the extreme timidity it always expresses with regard to rain; for though it has a shell that would secure it against the wheel of a loaded cart, yet does it discover as much solicitude about rain as a lady dressed in all her best attire, shuffling away on the first sprinklings, and running its head up in a corner. If attended to, it becomes an excellent weather-glass; for as sure as it walks elate, and in a manner on tip-toe, feeding with great earnestness, in a morning, so sure will it rain before night. It is totally a diurnal animal, and never pretends to stir after it becomes dark.

"The tortoise," adds Mr. White, "like other reptiles, has an arbitrary stomach, as well as lungs, and can refrain from eating, as well as breathing, for a great part of the year. I was much taken with its sagacity, in discerning those that do it kind offices: for as soon as the good old lady comes in sight who has waited on it for more than thirty years, it hobbles towards its benefactress with awkward alacrity; but remains inattentive to strangers. Thus, not only "the ox knoweth his owner, and the ass his master's crib," but the most abject and torpid of beings distinguishes the hand that feeds it, and is touched with the feelings of gratitude. This creature not only goes under the earth from the middle of November to the middle of April, but sleeps great part of the summer: for it goes to bed in the longest days at four in the afternoon, and often does not stir in the morning till late. Besides, it retires to rest for every shower, and does not move at all in wet days. When one reflects on the state of this strange being, it is a matter of wonder Providence should bestow such a seeming waste of longevity on a reptile that appears to relish it so little as to squander away more than two-thirds of its existence in a joyless stupor, and be lost to all sensation for months together in the profoundest of all slumbers! Though he loves warm weather, he avoids the hot sun; because his thick shell, when once heated, would, as the poet says of solid armour, 'scald with safety.' He therefore spends the more sultry hours under the umbrella of a large cabbage-leaf, or amidst the waving forests of an asparagus-bed. But as he avoids heat in the summer, so in the decline of the year, he improves the faint autumnal beams, by getting within the reflection of a fruit-tree wall; and though he has never read that planes inclining to the horizon receive a greater share of warmth, he inclines his shell by tilting it against the wall, to collect and admit every feeble ray."

2. Testudo marginata, marginated tortoise. The general colour of this animal is a dark or blackish bay; the middle or convex part of the pieces composing the disk, being more or less dashed or varied, in an irregular manner, with yellow: the marginal pieces are also variegated with the same colour, which predominates chiefly on the hindermost or widest divisions, which are pretty distinctly striated or furrowed, and from their peculiar width or dilatation form the chief part of the specific character. The under shell is of a pale yellow colour, each division being marked on its upper commissure by a transverse blackish band, running into a pair of pointed or subtriangular processes, extending nearly to the next or inferior division. The outline of the shell, if viewed from above, will be found to be much longer in proportion than that of the testudo græca, accompanied by a slight contraction or sinking in on each side.

The true native country of the animal seems not very distinctly known. Mr. Schoepf is inclined to think it an American species.

3. Testudo Indica, Indian tortoise. This very large terrestrial species, which is omitted by Linnæus in the twelfth edition of the Systema Naturæ, was first described by Perrault in the History of Animals published by the Royal Academy of France. The specimen was taken on the coast of Coromandel, and measured four feet and a half from the tip of the nose to the tail; and its height or convexity was fourteen inches: the shell itself was three feet long and two broad, and, like every other part of the animal, was of a dull-brown colour: the shield consisted of a large and dissimilar piece, and the edge on the fore part was rather reflected, for the easier motion of the animal's head: the head was seven inches long; the mandibles serrated, and furnished with an additional internal row of denticulations: the fore legs were nine inches long: the fore feet undivided, thick, and armed with five blunt claws: the hind legs were eleven inches long; the feet tetradactylous, and armed with four claws: the tail six inches thick at the base, fourteen inches long, and terminated by a horny curved process.

4. Testudo lutaria, mud-tortoise. This, which is supposed by the count de Cepede to be the testudo lutaria of Linnæus, is said to be extremely common in many parts of Europe, as well as Asia, being found in India, Japan, &c. It is, in general, not more than seven or eight inches long from the tip of the nose to that of the tail, and about three or four inches in breadth: the disk consists of thirteen pieces, which are striated and slightly punctuated in the centre, and along the middle range runs a longitudinal carina: the margin consists of twenty-three pieces, bordered with slight striæ: the colour of the shell is blackish, more or less deep in different specimens, and the general colour of the skin itself is similar: the feet are webbed, and there are five toes before, and four behind. Like other tortoises, it sometimes utters a kind of broken or interrupted hiss. This animal is, according to Cepede, no where more common than in France, and is particularly plentiful in Languedoc, and in many parts of Provence; and in a lake of about half a league wide, situated in the plain of Durance, were found such vast quantities, that the neighbouring peasantry were in a manner supported by them for more than three months together.

Though this species is aquatic, it always lays its eggs on land; digging for that purpose a hollow in the ground, and covering the eggs with the mould: the shell is less soft than those of the sea-tortoises or turtles, and the colour less uniform. When the young are first hatched they measure about six lines in diameter. This animal walks much quicker than the land-tortoise, especially when on even ground. It grows for a long time, and has been known to live more than twenty-four years. The taste which it has for small snails, and such kind of wingless insects as frequent the neighbourhood of the waters it inhabits, makes it useful in a garden, which it delivers from noxious animals, without doing any mischief itself. Like other tortoises, it may be rendered domestic, and may be kept in a bason or receptacle of water, so contrived on the edges as to give a ready egress to it when it wishes to wander about for prey. The count de Cepede adds, that though useful in gardens, it is found to be a very troublesome inmate in fish-ponds; attacking and destroying the fish: biting them in such a manner that they become enfeebled by loss of blood, and then dragging them to the bottom and devouring them; leaving only the bones and some of the cartilaginous parts of the head, and sometimes the air-bladder also, which floating on the surface, give notice of the en mies with which the pond is infested.

5. Testudo picta, painted tortoise. The remarkable colours of the shield of this species are sufficient to distinguish it from all others: the shell is of a smooth surface, of a flattened or but slightly convex form, and of a chesnut-brown colour, paler or darker in different individuals, and consisting, as usual, of thirteen segments, each of which is of a form approaching to square, and pretty deeply edged or bordered with pale yellow: a stripe of the same colour also runs down the middle of the dorsal segments, while the marginal pieces, which are twenty-five in number, are each marked by a semi-oval spot of the same colour at the edge, surrounded by two, or sometimes by three yellow bands, following the direction of the first-mentioned spot, and thus forming so many semi-elliptic yellow zones or stripes on each piece. The neatness and accuracy of these, as well as of the yellow borders on the large or middle segments of the shell, vary, as may be supposed, on different individuals, and in general seem most distinctly expressed on the smallest specimens. This may be considered as one of the middle-sized tortoises: the shell measuring from four to six inches in length, or somewhat more: the head is moderately small, and covered with a smooth skin; blackish above, but yellow on the sides and under part, and very elegantly streaked in a longitudinal direction, with several double rows of black streaks: the legs are blackish, and marked with two longitudinal yellow stripes: the claws are sharp and long, those on the fore feet five in number, and those on the hind feet four. The tail is blackish, scaly, moderately sharp-pointed, and marked on each side with yellow streaks. It is a fresh-water species, and inhabits slow and deep rivers in North America. In clear sunny weather these animals are said to assemble in multitudes, sitting on the fallen trunks of trees, stones, &c. and immediately plunging into the water on the least disturbance. They are said to swim very swiftly, but to walk slowly; to be able to continue many hours entirely beneath the water, but not to survive many days if kept out of their favourite element. They are very voracious, destroying ducklings, &c. which they seize by the feet, and drag under water. They are sometimes used as a food. The colour, as has been above observed, varies; being sometimes of a blackish brown, at other times of a reddish chesnut: the yellow markings are also either pale or deep in different individuals, and sometimes whitish: the inferior or under edges of the upper shell, as well as the upper edges or commissures of the lower, are elegantly streaked with black, as if artificially painted, and this variegation is continued over the skin of the sides of the body.

6. Testudo elegans, elegant tortoise. The animal described and figured by Seba, under the title of testudo terrestris ceilonica elegans minor, is a small land tortoise, with the shell nearly circular in its outline, and about two inches in length: its colour is a bright yellow, its surface apparently smooth, and at each of the commissures or joinings of the pieces composing the disk is a large oval, or rather leaf-shaped, black or dark-brown transverse spot; the pattern forming three rows of transverse spots down the disk; and at the upper junctures, or those where the ultimate pieces of the disk join those of the margin, is a broad spot of a more fasciated form: there are also two rather irregular or slightly flexuous black lists running down the shell, between the rows of spots: the marginal pieces are each marked by a transverse black belt or zone, thus forming a spotted edge round the whole: the head appears to be short and thick, and covered with small scales: the feet short, strong, scaly, and unwebbed, as in other land-tortoises, and furnished with five claws on each: the tail very short. Nothing particular seems to be known of its history.

7. Testudo tricarinata, tricarinated tortoise. This agrees as to shape and other particulars with Linnæus's description of his T. orbicularis. Its size scarce exceeds that of a large walnut; its colour is blackish; the shell consisting of thirteen scutella, each row marked on the middle by a longitudinal carina, and wrinkled with several lateral furrows and roughish points; the marginal pieces are twenty-three in number; the head is large, and of a brown colour, variegated on the sides with white: the legs short, strong, and covered with a scaly skin: on the fore feet are five distinct toes, connected to the very tips by a web, and terminated by so many sharp, crooked claws: the hind feet have only four toes, with sharp claws, and connected also by a web, with the appearance of a small unarmed fifth or spurious toe: the tail is short, conical, scaly, pointed, and but little exceeding the margin of the shell in length: the under shell is yellowish, spotted, and varied with brown. See Plate Nat. Hist. fig. 398.

8. Testudo scabra, rough tortoise. The shell of the species quoted by Linnæus in his description of T. scabra is figured in its natural size in the work of Seba, who affirms that it never grows larger than represented in his figure; measuring about two inches and a half in length, and near two inches in breadth; being of a cordated figure, or somewhat pointed at the bottom. Its colour, according to Seba, is light reddish, prettily variegated on the head and shell with white lines and spots, in a kind of flamy or wavy pattern: the feet are marked with red specks, and have each five toes with sharp claws: the head is very prominent, and the eyes small: down the back of the disk are represented in Seba's engraving three very conspicuous white lines or carinæ; so that the title of tricarinata would apply to this, as well as to the species so denominated by Mr. Schoepf.

9. Testudo ferox, fierce tortoise. This remarkable species is distinguished by the unusual nature of its shield, which is hard or osseous on the middle part only, while the edges gradually degenerate into a flexile coriaceous verge: this shield is obscurely marked with five or six transvere bands, and granulated with small warts or prominences, which gradually enlarge as they approach the leathery or flexible edge: the head is rather small, and of an unusual shape, being somewhat trigonal, with the snout very much lengthened, and the upper part drawn out into a subcylindric form, terminated by the nostrils, and projecting much beyond the lower mandible: the neck, when retracted, appears very thick, and surrounded by many wreaths or folds of skin; but when exerted, is of very great length, so as nearly to equal that of the whole shell: the legs are short, thick, and covered with a wreathed skin: the feet are all furnished with strong and broad webs, connecting the three last toes of each; the three first on each foot are furnished with pretty strong claws, but the remaining ones are unarmed; and besides the real or proper toes, there are two spurious or additional ones on the hind, and one on the fore feet, serving to strengthen and expand the web to a greater degree: the tail is short, pointed, and curving inwards: the eyes are very small and round. The colour of this animal on the upper parts is a deep-brownish olive, and on the under parts white; the shell being marked beneath in a very elegant manner, with ramifications of vessels disposed upon it.

This species is found in Pennsylvania, Carolina, &c. &c. and, contrary to the nature of most others of the tr e, is possessed of very considerable vigour and swiftness of motion, springing forwards towards its assailant, when disturbed or attacked, with great fierceness and alacrity. Its length is about a foot and half, or more, and its breadth about fifteen inches. It was first described by Dr. Garden, who communicated it to Mr. Pennant, by whom it was introduced into the Philosophical Transactions. A specimen examined by Dr. Garden weighed twenty-five pounds, but it is said to grow so large as to seventy pounds. The individual mentioned by Dr. Garden laid fifteen eggs during the time it was kept, which were exactly spherical, more than an inch in diameter, and fifteen more were found on dissection. Its flesh is said to be extremely delicate, being equal, if not superior, even to that of the green turtle.

The great soft-billed turtle, described by Mr. Bartram in his Travels, appears to be the same with this. It is said by Mr. Bartram to be of a flat form, two feet and a half long, and a foot and a half broad: the shield soft and cartilaginous on each side, and this part sometimes becomes gelatinous on boiling: the fore and hind part of the shield is beset with round horny warts or tubercles: the sternum or under shell semicartilaginous, except on the middle, where it is bony: the head large and clubbed, and of an oval form: the nose extended, truncated in the manner of a hog's snout: the eyes large, and seated at its base: mouth wide; the edges tumid and wrinkled, and bearded by several long pointed warts or processes, which are extensile at the pleasure of the animal, and give it an ugly and forbidding aspect. Mr. Bartram's figure also represents the throat and part of the neck as furnished with similar warts. Mr. Bartram adds, that it is fond of the muddy parts of rivers, &c. hiding itself among the roots and leaves of water-plants, and thence springing on its prey, stretching out its neck to an incredible length, and seizing with wonderful celerity young birds, &c. &c. It is found in all the rivers, lakes, and pools, of East Florida, weighing from thirty to forty pounds. The warts or processes on each side the neck may constitute perhaps a sexual difference in this species, since they are not to be found in that described by Dr. Garden and Mr. Pennant. See Plate Nat. Hist. fig. 396.

10. Testudo serpentina, snake tortoise. This species, first described by Linnæus, appears to have been very obscurely known;

having been figured in no work of natural history till it was introduced into Mr. Schoepf's publication. It is a native of North America, where it inhabits stagnant waters, growing to the weight of fifteen or twenty pounds, and even more, and preying on fish, ducklings, &c. &c. seizing its prey with great force, stretching out its neck and hissing at the same time. Whatever it seizes in its mouth it holds with great force, and will suffer itself to be raised up by a stick rather than quit its hold. The head is large, depressed, triangular, and covered with a scaly and warty skin: the orbits of the eyes are oblique; the mouth wide; the mandibles sharp; the neck covered by scaly warts, and appearing short and thick when the animal is at rest, but when in the act of springing on its prey, is stretched out to a third part of the length of the shell: the toes of all the feet are distinct, but connected by a web; and are five in number on the fore feet, and four on the hind; all armed with claws longer than the toes themselves: the tail is straight, and about two-thirds the length of the shell; it is compressed, attenuated, and crested on the upper part with sharp bony scales directed backwards and gradually decreasing to the tip, while the sides and under part are covered with smaller scales: the under part of the body is covered by a loose, wrinkled skin, beset with smallish soft scales and granules: the shell is slightly depressed, of an oval form, and consists of thirteen pieces in the disk, each of which rises behind into a kind of projection or obtuse point, and is pretty strongly radiated and furrowed in different directions; the general colour of the whole is a dull chesnut-brown, lighter or paler beneath.

This animal conceals itself in muddy waters in such a manner as to leave out only a part of its back, like a stone or other inanimate object, by which means it the more easily obtains its prey. Mr. Pennant, in the supplement to his Arctic Zoology, mentions this as a new species, under the name of serrated tortoise. In New York it is known by the title of the snapping tortoise. Linnæus seems to have been mistaken in supposing it a native of China.

Sea-tortoises, or turtles.

The marine tortoises, or turtles as they are commonly called, are distinguished from those of the preceding division by their very large and long fin-shaped feet, in which are inclosed the bones of the toes; the first and second alone on each foot being furnished with visible or projecting claws, the others not appearing beyond the edge. The shield, as in the land-tortoises, consists of a strong bony covering, in which are imbedded the ribs, and which is coated externally by hard horny plates, in one or two species much thicker or stronger than those of the land-tortoises.

1. Testudo coriacea, coriaceous turtle. Of all the marine tortoises this appears to grow to the largest size, having been sometimes seen of the length of eight feet, and of the weight of a thousand pounds. It differs from the rest of its tribe in the form of its body, which is longer in proportion, and still more in its external covering, which, instead of being of a horny nature, as in others, is of a substance resembling strong leather, marked over the whole surface into small, obscurely subhexagonal and pentagonal subdivisions or lineations, which do not take away from the general smoothness of the surface. Along the whole length of this covering or leathery shield run five distinct, strongly prominent, tuberculated ribs or ridges; and indeed if those which border the sides are taken into the account, we may say there are seven ridges on the shield. There is no under or thoracic shell, so that the animal might form a distinct genus from the rest of the tortoise tribe. The head is large, and the upper mandible notched at the tip in such a manner as to give the appearance of two large teeth or processes, between which, when the mouth is closed, is received the tip of the lower mandible. The fins or legs are large and long, and covered with a tough leathery skin: the tail is rather short and sharp-pointed. The general colour of the whole animal is dusky brown, paler beneath. This singular species is a native of the Mediterranean sea, and has at different periods been taken on the coasts both of France and England. In the month of August, in the year 1729, a specimen was taken about three leagues from Nantz, not far from the mouth of the river Loire, and which measured seven feet one inch in length, three feet seven inches in breadth, and two feet in thickness. It is said to have uttered a hideous noise when taken, so that it might be heard to the distance of a quarter of a league; its mouth at the same time foaming with rage, and exhaling a noisome vapour. In the year 1778, a specimen was taken on the coast of Languedoc, which measured seven feet five inches in length. In July, 1756, one was taken on the coast of Cornwall, which, according to Dr. Borlace, "measured six feet nine inches from the tip of the nose to the end of the shell; ten feet four inches from the extremities of the fore fins extended; and was adjudged to weigh eight hundred pounds weight." The fine specimen lately in the Leverian Museum was of similar weight, and was taken on the coast of Dorsetshire.

This species is found not only in the European seas, but in those of South America also, and occasionally appears about some of the African coasts.

According to Cepede, the coriaceous tortoise is one of those with which the Greeks were well acquainted, and he supposes it to have been the species particularly used in the construction of the antient lyre or harp, which was at first composed by attaching the strings or wires to the shell of some marine tortoise. We may add, that the ribs or prominences on the back of the shell bear an obscure resemblance to the strings of a harp, and may have suggested the name of luth or lyre, by which it is called among the French, exclusive of the use to which the shell was antiently applied.

The coriaceous tortoise, says Mr. Pennant, is reputed to be extremely fat, but the flesh coarse and bad: the Carthusians, however, will eat no other species.

It may be added, that the small sea-tortoise described by Mr. Pennant, in the Philosophical Transactions for the year 1771, is evidently no other than the young of this animal. See Plate Nat. Hist. fig. 395.

2. Testudo mydas. The green turtle, so named, not on account of its being externally of that colour, but from the green tinge which its fat frequently exhibits when the animal is taken in its highest state of perfection, may be considered as one of the largest of this genus, often measuring above five feet in length, and weighing more than five or six hundred pounds. Its shell is of a somewhat heart-shaped form, or pointed at the extremity, and consists of thirteen dorsal segments or divisions surrounded by twenty-five marginal pieces. Its colour is a dull palish-brown, more or less variegated with deeper undulations, but not exhibiting those strong and beautiful colours which so peculiarly distiguish that of the T. imbricata, or hawk's-bill turtle, which affords the tortoise-shell used for ornamental purposes and in various manufactures, having neither sufficient strength nor beauty; but so much is the flesh esteemed, that the inhabitants of the West Indian islands have long considered it as one of the most excellent articles of food, and have gradually succeeded in introducing a similar taste among some of the European nations. In our own country in particular it is in the highest estimation, and is regularly imported in considerable quantities to supply the luxury of the metropolis. The introduction of the green turtle as an article of luxury into England is of no very distant date, and perhaps can hardly be traced much farther than about fifty or sixty years backward. In reality, so little was the nature of the sea-tortoises understood by the Europeans before that period, that the different kinds were in general confounded by navigators, whose accounts relative to their character as a food varied according to the species which they happened to take for that purpose; some insisting that the turtle was a coarse and unpalatable diet, while others considered it as of the highest degree of excellence.

"Of the sea-turtles," says Catesby, "the most in request is the green turtle, which is esteemed a most wholesome and delicious food. It receives its name from the fat, which is of a green colour. Sir Hans Sloane informs us, in his History of Jamaica, that forty sloops are employed by the inhabitants of Port Royal, in Jamaica, for the catching them. The markets are there supplied with turtle as ours are with butcher's meat. The Bahamians carry many of them to Carolina, where they turn to good account; not because that plentiful country wants provisions, but they are esteemed there as a rarity, and for the delicacy of their flesh. They feed on a kind of grass, growing at the bottom of the sea, commonly called turtle-grass. The inhabitants of the Bahama islands, by often practice, are very expert at catching turtles, particularly the green turle. In April they go, in little boats, to Cuba and other neighbouring islands, where, in the evening, especially in moonlight nights, they watch the going and returning of the turtle to and from their nests, at which time they turn them on their backs, where they leave them, and proceed on, turning all they meet; for they cannot get on their feet again when once turned. Some are so large that it requires three men to turn one of them. The way by which the turtle are most commonly taken at the Bahama islands is by striking them with a small iron peg of two inches long, put in a socket, at the end of a staff of twelve feet long. Two men usually set out for this work in a little light boat or canoe, one to row gently and steer the boat, while the other stands at the head with his striker. The turtle are sometimes discovered by their swimming with their head and back out of the water, but they are often discovered lying at the bottom, a fathom or more deep. If a turtle perceives he is discovered, he starts up to make his escape: the men in the boat pursuing him, endeavour to keep sight of him, which they often lose, and recover again by the turtle putting his nose out of the water to breathe: thus they pursue him, one padding or rowing, while the other stands ready with his striker. It is sometimes half an hour before he is tired: then he sinks at once to the bottom, which gives them an opportunity of striking him; which is by piercing him with an iron peg, which slips out of the socket, but is fastened with a string to the pole. If he is spent and tired by being long pursued, he tamely submits, when struck, to be taken into the boat or hauled ashore. There are men who by diving will get on their backs, and by pressing down their hind parts, and raising the fore-part of them by force, bring them to the top of the water, while another slips a noose about their necks."

Though the green turtle is a native of the West Indian seas, yet it is sometimes driven by storms out of its usual residence, and instances have occurred in which it has been taken on the coasts of Europe. An occurrence of this kind is said by the count de Cepede to have happened in France, a turtle having been taken at Dieppe in the year 1752, which weighed between eight and nine hundred pounds, and was almost six feet in length, and four wide. It may, however, be doubted whether this animal was not rather a caretta or loggerhead, than a green turtle. Another, of still larger size, is also said to have been taken on the coast of France, about two years afterwards.

"The sea-tortoises, or turtles in general," says Catesby, "never go on shore but to lay their eggs, which they do in April: they then crawl up from the sea above the flowing of high water, and dig a hole above two feet deep in the sand, into which they drop in one night above a hundred eggs, at which time they are so intent upon nature's work, that they regard none that approach them; but will drop their eggs into a hat, if held under them; but if they are disturbed before they begin to lay, they will forsake the place, and seek another. They lay their eggs at three, and sometimes at four different times; there being fourteen days between every time; so that they hatch and creep from their holes into the sea at different times also. When they have laid their complement of eggs, they fill the hole with sand, and leave them to be hatched by the heat of the sun, which is usually performed in about three weeks." It may be proper to add, that the eggs are about the size of tennis-balls, round, white, and covered with a smooth parchment-like skin. See Plate Nat. Hist. fig. 399.

3. Testudo caretta, loggerhead turtle. This species exceeds in size every other yet known, except perhaps the coriacea. In its general appearance it most resembles the mydas or green turtle, but is distinguished by the superior size of the head, the proportional breadth of the shell, and by its deeper and more variegated colours, resembling those of the T. imbricata, or hawk's-bill; but its principal mark of distinction consists in the number of dorsal segments or scutella of the shell, which instead of thirteen, as in other species, amount to fifteen; the lateral as well as the middle range containing five pieces, of which the two superior are considerably smaller than the rest. The fore feet are very large and long; the hind feet much shorter, though broad. This animal inhabits the same seas with the green turtle, but is also diffused into very remote latitudes, being often found in the Mediterranean, and in particular about the coasts of Italy and Sicily. Considered in a commercial view, it is of little or no value; the flesh being coarse and rank, and the laminæ or plates of the shell too thin for general use. It is said, however, to afford a good quantity of oil, which may be used for lamps, &c. The loggerhead turtle is a very strong and fierce animal, and is even dangerous; defending itself with great vigour with its legs, and being able to break the strongest shells and other substances with its mouth. Aldrovandus assures us, that on offering a thick walking-stick to one which he saw publicly exhibited at Bologna, the animal bit it in two in an instant.

"The loggerhead turtles," says Catesby, "are the boldest and most voracious of all turtles; their flesh is rank, and therefore little sought for, which occasions them to be more numerous than any other kind. They range the ocean over, an instance of which, among many others that I have known, happened on the 20th of April, 1725, in lat. 30 degrees north; when our boat was hoisted out, and a loggerhead turtle struck as it was sleeping on the surface of the water: this by our reckoning, appeared to be the midway between the Azores and the Bahama islands; either of which places being the nearest land it could come from, or that they are known to frequent; there being none on the north continent of America, farther north than Florida. It being amphibious, and yet at so great a distance from land in the breeding-time, makes it the more remarkable. They feed mostly on shell-fish, the great strength of their beaks enabling them to break very large shells, as the large buccinums and trochi."

4. Testudo imbricata, the hawk's-bill turtle. The testudo imbricata is so named from the peculiar disposition of its scales or laminæ, which commonly lap over each other at their extremities in the manner of tiles on the roof of a building. The outline of the shell, viewed from above, is more heart-shaped than in other sea-tortoises, and terminates more acutely: each of the middle row of scales on the back is also of a sharpened form at the tip, more especially in the young or half-grown animal, and has a ridge or carina down the middle: the head is smaller in proportion than in other turtles; the neck longer; and the beak narrower, sharper, and more curved, so as to bear no inconsiderable resemblance to the bill of a hawk, from which circumstance the animal derives its common or popular name of the hawk's-bill turtle. The fore legs are longer than in the rest of the tribe, and it is said that when turned or laid on its back, the animal is enabled by their assistance, to reach the ground in such a manner as to recover its former situation, which no other turtle can do. In old specimens the neatness of the shell, and the well-defined outline of the scales, are occasionally impaired, and this seems to be one principal reason of its having been sometimes confounded with the caretta, or loggerhead turtle. The hawk's-bill turtle is a native of the Asiatic and American seas, and is sometimes, though less frequently, found in the Mediterranean. Its general length seems to be about three feet, from the tip of the bill to the end of the shell; but it has been known to measure five feet in length, and to weigh five or six hundred pounds. In the Indian ocean in particular, specimens are said to have occurred of prodigious magnitude.

The shell of this animal was anciently used for a shield, and still serves for that purpose among barbarous nations. The flesh is in no estimation as a food; the lamellæ or plates of the shell, which are far stronger, thicker, and clearer than in any other kind, constituting the sole value of the animal, and affording the substance particularly known by the name of tortoise-shell: they are semitransparent, and most elegantly variegated with whitish, yellowish, reddish, and dark-brown clouds and undulations, so as to constitute, when properly prepared and polished, one of the most elegant articles for ornamental purposes. See Tortoise-shell.

The natural or general number of the dorsal pieces is thirteen; the marginal row consisting of twenty-five smaller pieces. This external coating is raised or separated from the bony part, which it covers, by placing fire beneath the shell; the heat soon causing the plates to start, so as to be easily detached from the bone. These plates vary in thickness, according to the age and size of the animal, and measure from an eighth to a quarter of an inch in thickness. A large turtle is said to afford about eight pounds of tortoise-shell.

In order to bring tortoise-shell into the particular form required on the part of the artist, it is steeped in boiling water, till it has acquired a proper degree of softness, and immediately afterwards committed to the pressure of a strong metallic mould of the figure required; and where it is necessary that pieces should be joined, so as to compose a surface of considerable extent, the edges of the respective pieces are first scraped or thinned, and being laid over each other during their heated state, are committed to a strong press, by which means they are effectually joined or agglutinated. These are the methods also by which the various ornaments of gold, silver, &c. are occasionally affixed to the tortoise-shell.

The Greeks and Romans appear to have been peculiarly partial to this elegant ornamental article, with which it was customary to decorate the doors and pillars of their houses, their beds, &c. &c. In the reign of Augustus this species of luxury seems to have been at its height in Rome.

"The Egyptians," says Mr. Bruce, in the supplement to his Travels, "dealt very largely with the Romans in this elegant article of commerce. Pliny tells us the cutting them for fineering or inlaying was first practised by Carvilius Pollio, from which we should presume, that the Romans were ignorant of the art of separating the laminæ by fire placed in the inside of the shell, when the meat is taken out: for these scales, though they appear perfectly distinct and separate, do yet adhere, and oftener break than split, where the mark of separation may be seen distinctly. Martial says that beds were inlaid with it. Juvenal, and Apuleius in his tenth book, mention that the Indian bed was all over shining with tortoise-shell on the outside, and swelling with stuffing of down within. The immense use made of it in Rome may be guessed at by what we learn from Velleius Paterculus, who says, that when Alexandria was taken by Julius Cæsar, the magazines or warehouses were so full of this article, that he proposed to have made it the principal ornament of his triumph, as he did ivory afterwards, when triumphing for having happily finished the African war. This too, in more modern times, was a great article in the trade to China."

It may be doubted however, whether the species described and figured by Mr. Bruce, and said to inhabit the Red Sea, is the real T. imbricata; since it appears to differ in some respects from the usual character of this animal, and particularly in not having imbricated scales.

Testudo, in the military art of the antients, was a kind of cover or screen which the soldiers, *e. gr.* a whole company, made themselves of their bucklers, by holding them up over their heads, and standing close to each other. This expedient served to shelter them from darts, stones, &c. thrown upon them, especially those thrown from above, when they went to the assault.

Testudo was also a kind of large wooden tower which moved on several wheels, and was covered with bullocks'-hides, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams.

TETHYS, a genus of insects belonging to the class of vermes, and order of mollusca. The body is oblong, fleshy, and without feet; the mouth consists of a cylindrical proboscis under the duplicature of a lip; and there are two foramina at the left side of the neck. The species are two, both inhabitants of the ocean.

TETRACERA, a genus of plants of the class polyandria, and order tetragynia, and in the natural system ranging under the doubtful. The calyx is hexaphyllous, and the capsules four. There are 12 species, shrubs of South America.

TETRACHORD, in music, (from the Greek,) a concord in the music of the antients consisting of three degrees, or intervals, and four terms, or sounds; called by the Greeks also diatessaron, and by us a fourth. In this system the extremes were fixed, but the middle sounds were varied according to the mode.

In the antient music, all the primitive or chief divisions were confined to four chords, so that the great scale consisted of replicates, and all the upper tetrachords were considered only as repetitions of the first or lowest.

TETRADIAPASON, the Greek appellation of the quadruple octave, which we also call the 29th. The system of the antients not extending to this interval, they only knew it in imagination, or by name.

TETRADYNAMIA (τεσσαρες, four, and δυναμις, power), four powers; the name of the 15th class in Linnæus's sexual system. See Botany.

TETRAEDRON, or Tetrahedron, in geometry, is one of the five Platonic or regular bodies or solids, comprehended under four equilateral and equal triangles. Or it is a triangular pyramid of four equal and equilateral faces.

It is demonstrated in geometry, that the side of a tetraedron is to the diameter of its circumscribing sphere, as $\sqrt{2}$ to $\sqrt{3}$; consequently they are incommensurable.

If a denotes the linear edge or side of a tetraedron, b its whole superficies, c its solidity, r the radius of its inscribed sphere, and R the radius of its circumscribing sphere; then the general relation among all these is expressed by the following equations, viz.

$$a = 2r\sqrt{6} = \tfrac{2}{3}R\tfrac{1}{3}\sqrt{6} = \sqrt{\tfrac{1}{3}b\sqrt{3}} = \sqrt[3]{6c\sqrt{2}}.$$

$$b = 24r^2\sqrt{3} = \tfrac{8}{3}R^2\sqrt{3} = a^2\sqrt{3} = 6\sqrt[3]{c^2\sqrt{3}}.$$

$$c = 8r^3\sqrt{3} = \tfrac{8}{27}R^3\sqrt{3} = \tfrac{1}{12}a^3\sqrt{2} = b\sqrt{2b\sqrt{3}}.$$

$$R = 3r = \tfrac{1}{4}a\sqrt{6} = \tfrac{1}{4}\sqrt{2b\sqrt{3}} = \tfrac{3}{2}\sqrt[3]{\tfrac{1}{3}c\sqrt{3}}.$$

$$r = \tfrac{1}{3}R = \tfrac{1}{12}a\sqrt{6} = \tfrac{1}{32}\sqrt{2b\sqrt{3}} = \tfrac{1}{2}\sqrt[3]{\tfrac{1}{3}c\sqrt{3}}.$$

TETRAGONIA, a genus of plants of the class of icosandria, and order monogynia; and in the natural system ranging under the 13th order, succulentæ. The calyx is divided into three, four, or five parts. There is no corolla; the drupe is beneath, and the nut three or eight-celled. There are eight species; the puticosa, decumbens, herbacea, echinata, expansa, crystallina, hirsuta, and spicata, chiefly natives of the Cape.

TETRAGYNIA (τεσσαρες, four, and γυνη, a woman), the name of an order, or secondary division, in the 4th, 5th, 6th, 8th, and 13th classes in the sexual system. See Botany.

TETRALOMA, a genus of insects of the coleoptera order. The generic character is, antennæ clavate, the club perfoliate, less rounded, entire; feelers thickish, unequal; shells as long as the abdomen. There are two species of this insect, viz. the T. fungorum, and the T. ancora.

TETRANDRIA (τεσσαρες, four, and ανηρ, a man or husband), the name of the fourth class in Linnæus's sexual system. See Botany.

TETRANTHUS, a genus of the syngenesia polygamia segregata class and order of plants. The calyx is common, four-flowered; perianthium proper, one-leafed; seeds crowned. There is one species, an annual of Hispaniola.

TETRAO, in ornithology, a genus of birds belonging to the order of gallinæ, and thus characterised by Linnæus: there is a spot near the eyes naked or papillose, or covered, though more rarely, with feathers. Gmelin has enumerated about 66 species. The genus tetrao comprehends both the grouse, partridge, and quail; but Dr. Latham, with great judgment and propriety, has made two genera of them, under the names of tetrao, comprehending the grouse; and perdix, comprehending the partridge and quail. Dr. Latham thus distinguishes the genus tetrao: the bill is like a crooked cone, with a naked scarlet skin above each eye, and the feet feathered to the toes. The perdix he characterizes by a bill convex, strong, and short; the nostrils are covered above with a callous prominent rim; the orbits are papillose; the feet naked, and most of the species are furnished with spurs. He reckons twenty species under the tetrao, and forty-eight under the perdix.

I. Tetrao. Of this genus the following species are found in Britain: 1. The urogallus, or cock of the wood, inhabits woody and mountainous countries; in particular, forests of pines, birch-trees, and junipers; feeding on the tops of the former, and berries of the latter; the first often infects the flesh with such a taste as to render it scarcely eatable. In the spring it calls the females to its haunts with a loud and shrill voice; and is at that time so very inattentive to its safety, as to be very easily shot. It stands perched on a tree, and descends to the females on their first appearance. They lay from eight to sixteen eggs; eight at the first, and more as they advance in age.

This bird is common to Scandinavia, Germany, France, and several parts of the Alps. It is found in no other part of Great Britain than the Highlands of Scotland, north of Inverness; and is very rare even in those parts.

The length of the male is two feet nine inches; its weight sometimes fourteen pounds. The female is much less, the length being only twenty-six inches. The sexes differ also greatly in colours. The bill of the male is of a pale yellow; the head, neck, and back, are elegantly marked, slender lines of grey and black running transversely. The upper part of the breast is of a rich glossy green; the rest of the breast and belly black, mixed with some white feathers; the sides are marked like the neck; the coverts of the wings crossed with undulated lines of black and reddish brown; the exterior webs of the greater quill-feathers are black: the tail consists of eighteen feathers, the middle of which is the longest; these are black, marked on each side with a few white spots. The legs are very strong, and covered with brown feathers; the edges of the toes are pectinated. Of the female, the bill is dusky; the throat red; the head, neck, and back, are marked with transverse bars of red and black: the breast has some white spots on it, and the lower part is of a plain orange-colour; the belly is barred with pale-orange and black; the tips of the feathers are white. The tail is of a deep rust-colour, barred with black, tipped with white, and consists of sixteen feathers.

2. The tetrix, black grouse, or black-cock, like the former species, is fond of woody and mountainous situations; feeding on the vaccinum, and other mountain-fruits, and in the winter on the tops of the heath. In the summer they frequently descend from the hills to feed on corn. They never pair: but in the spring the male gets upon some eminence, crows and claps his wings; on which signal all the females within hearing resort to him. The hen lays seldom more than six or seven eggs. When the female is obliged, during the time of incubation, to leave her eggs in quest of food, she covers them up so artfully with moss or dry leaves, that it is very difficult to discover them. On this occasion she is extremely tame and tranquil, however wild and timorous at other times. She often keeps

her nest though strangers attempt to drag
r away. As soon as the young ones are
tched, they are seen running with extreme
ility after the mother, though sometimes
ey are not entirely disengaged from the
ell. The hen leads them forwards for the
st time into the woods, to show them ants'
gs and the wild mountain-berries, which,
hile young, are their only food. As they
ow older their appetites grow stronger, and
ey then feed upon the tops of heath and
e cones of the pine-tree. In this manner
ey soon come to perfection; they are hardy
rds, their food lies every where before
em, and it would seem that they should in-
ease in great abundance. But this is not
e case; their numbers are thinned by rapa-
ous birds and beasts of every kind, and still
ore by their own salacious contests. As
on as the hatching is over, which the female
erforms in the manner of a hen, the whole
ood follows the mother for about a month
two; at the end of which the young males
tirely forsake her, and keep in great harmo-
y together till the beginning of spring. At
is season they begin to consider each other
rivals. They fight like game-cocks; and
that time are so inattentive to their own
fety, that it often happens that two or three
them are killed at a shot.

An old black cock is in length twenty-two
ches, and weighs near four pounds. The
ll is dusky; and the plumage of the whole
dy black, glossed over the neck and rump
ith a shining blue. The coverts of the
ings are of a dusky brown; the inner co-
erts white; the thighs and legs are covered
ith dark-brown feathers; the toes resemble
ose of the former species. The female
eighs only two pounds, and its length is one
ot six inches. The head and neck are
arked with alternate bars of dull red and
ack; the breast with dusky black and white;
t the last predominates. The back, co-
erts of the wings, and tail, are of the same
lours as the neck, but the red is deeper.
he tail is slightly forked. The feathers un-
r the tail are white, marked with a few bars
black and orange. This bird hatches its
ung late in the summer. It lays from six
eight eggs, of a dull yellowish-white co-
ur, marked with numbers of very small fer-
ginous specks; and towards the smaller
d with some blotches of the same hue. See
late Nat. Hist. fig. 400.

3. The scoticus, red game, or moor-fowl,
peculiar to the British islands. The male
eighs abont nineteen ounces; and is in
ngth $15\frac{1}{2}$ inches. The plumage on the head
d neck is of a light tawny red; each fea-
er is marked with several transverse bars of
ack. The back and scapular feathers are
a deeper red; and on the middle of each
ather is a large black spot; the breast and
lly are of a dull purplish brown, crossed
th numerous narrow dusky lines; the legs
d feet are clothed to the very claws with
ick soft white feathers. The claws are
itish, very broad and strong. The female
eighs only fifteen ounces. The colours in
neral are duller than those of the male.
hese birds pair in the spring, and lay from
to ten eggs. The young brood follow the
n the whole summer; in the winter they
in in flocks of forty or fifty, and become re-
arkably shy and wild; they always keep on
the tops of the hills, are scarcely ever found on the sides, and never descend into the valleys. Their food is the mountain-berries and tops of the heath.

4. The lagopus, white game, or ptarmigan, is fifteen inches in length, and weighs nineteen ounces. Its plumage is of a pale brown or ash-colour, elegantly crossed or mottled with small dusky spots and minute bars; the head and neck with broad bars of black, rust-colour, and white: the belly and wings are white, but the shafts of the greater quill-feathers black. In the male, the grey colour predominates, except on the head and neck, where there is a great mixture of red, with bars of white. The females and young birds have a great deal of rust-colour in them. The tail consists of sixteen feathers; the two middle of which are ash-coloured, mottled with black, and tipped with white; the two next black, slightly marked with white at their ends, the rest wholly black: the feathers incumbent on the tail are white, and almost entirely cover it.

Ptarmigans are found in these kingdoms only on the summit of the highest hills of the Highlands of Scotland, of the Hebrides and Orkneys; and a few still inhabit the lofty hills near Keswick in Cumberland, as well as the mountains of Wales. They live amidst the rocks, perching on the grey stones, the general colour of the strata in those exalted situations. They are very silly birds; so tame as to bear driving like poultry; and, if provoked to rise, take very short flights, making a great circuit like pigeons. Like the grouse, they keep in small packs; but never, like those birds, take shelter in the heath, but beneath loose stones. To the taste they scarcely differ from a grouse.

II. Perdix, comprehends both the partridge and quail.

In England the partridge is a favourite delicacy at the tables of the rich; and the desire of keeping it to themselves has induced them to make laws for its preservation, no way harmonising with the general spirit of English legislation.

The partridge seems to be a bird well known over all the old continent. Their manners resemble those of poultry in general; but their cunning and instinct seem superior to those of the larger kinds. Perhaps, as they live in the very neighbourhood of their enemies, they have more frequent occasion to put their little arts in practice, and learn by habit the means of evasion or safety. Whenever therefore a dog or other formidable animal approaches their nest, the female uses every means to draw him away. She keeps just before him, pretends to be incapable of flying, just hops up, and then falls down before him, but never goes off so far as to discourage her pursuer. At length, when she has drawn him entirely away from her secret treasure, she at once takes wing, and fairly leaves him to gaze after her in despair. After the danger is over, and the dog withdrawn, she then calls her young, who assemble at once at her cry, and follow where she leads them. There are generally from ten to fifteen in a covey; and, if unmolested, they live from fifteen to seventeen years.

2. The coturnix, or common quail, is not above half the size of the partridge. The feathers of the head are black, edged with rusty brown; the breast is of a pale yellowish red, spotted with black; the feathers on the back are marked with lines of pale yellow, and the legs are of a pale hue. Except in the colours thus described, and the size, it every way resembles a partridge in shape, and, except that it is a bird of passage, it is like all others of the poultry kind in its habits and nature.

The quail seems to spread entirely throughout the old world, but does not inhabit the new. It is observed to shift its quarters according to the season, coming northward in spring, and departing south in autumn, and in vast flocks, like other migrating birds. Twice in a year it comes in such vast quantities in Capri, that the bishop of the island draws the chief part of his revenue from them; hence he is called the quail-bishop. But this does not stand alone; almost all the islands in the Archipelago, on the opposite coasts, are at times covered with these birds, and some of them obtain a name from this circumstance. On the west coast of the kingdom of Naples, within the space of four or five miles, a hundred thousand have been taken in a day, which have been sold for eight livres per hundred to dealers who carry them for sale to Rome. Great quantities also sometimes alight in spring on the coasts of Provence, especially in the diocese of the bishop of Frejus, which is near the sea, and appear, at their first landing, so much fatigued that they are often taken by the hand.

With us they may be said not to be plenty at any time. They breed with us, and the major part migrate south in autumn; the rest only shift their quarters, as they have been met with on the coasts of Essex, and in Hampshire, in the winter season, retiring thence in October.

It feeds like the partridge, and, like that bird, makes no nest, except a few dry leaves or stalks scraped together may be called so, and sometimes a hollow on the bare ground suffices. In this the female lays her eggs to the number of six or seven, of a whitish colour, marked with irregular rust-coloured spots: the young follow the mother as soon as hatched, like young partridges. They have but one brood in a year.

Quail-fighting was a favourite amusement among the Athenians. They abstained from the flesh of this bird, deeming it unwholesome, as supposing that it fed upon the white hellebore: but they reared great numbers of them for the pleasure of seeing them fight; and staked sums of money, as we do with cocks, upon the success of the combat. Fashion, however, has at present changed with regard to this bird: we take no pleasure in its courage, but its flesh is considered as a very great delicacy. Quails are easily caught by a call: the fowler early in the morning having spread his net, hides himself under it among the corn; he then imitates the voice of the female with his quail-pipe, which the cock hearing, approaches with the utmost assiduity; when he has got under the net, the fowler then discovers himself, and terrifies the quail, who attempting to get away, entangles himself the more in the net, and is taken.

TETRODON, a genus of fishes of the order nantes. The generic character is, jaws bony, divided at the tip; body roughened beneath; ventral fins wanting.

1. Tetrodon lagocephalus, hare tetrodon. The fishes of this genus, of which there are 14 species, like the diodons, have the power of inflating their body at pleasure, by means of an internal membrane for that purpose, and during the time of inflation the small spines dispersed over their sides and abdomen are raised in such a manner as to operate as a defence against their enemies: they are chiefly natives of the tropical seas, though sometimes seen in the higher northern and southern latitudes, and are supposed to live principally on the crustaceous and testaceous animals.

The present species grows to the length of about twelve inches, and is of a thick form in front, the hinder parts tapering suddenly towards the tail: the colour is yellowish brown above, and whitish with a slight silvery cast beneath. This species occasionally strays into the northern latitudes, and has been taken, according to Mr. Pennant, about the British coasts, viz. near Penzance in Cornwall. It has the power of inflating the abdomen to a vast size: the Linnæan title seems to have been given from a fancied resemblance which the fore part of the head bears to that of a hare.

2. Tetrodon lineatus, lineated tetrodon. Length ten or twelve inches: shape somewhat square, but when inflated resembling that of the T. lagocephalus: whole body beset with numerous small spines: colour grey on the abdomen, with numerous, longitudinal, deep-brown streaks: fins and tail as in the preceding species. Native of the Mediterranean and American seas: sometimes found in the river Nile, where Hasselquist was assured by the fishermen that on being taken the hands were stung in the same manner as with nettles.

3. Tetrodon testudineus, tortoise-shell tetrodon. Length two feet; shape lengthened; colour rufous-brown above, marked by numerous round, pale-blue spots; beneath blueish or ash-coloured, beautifully varied by longitudinal brown streaks: fins and tail bright ferruginous: the whole abdomen is furnished with numerous small spines, which, when the animal is in a quiet state, are imbedded in so many corresponding cavities in the skin; but are elevated when the fish, on any alarm, distends its body. Native of the Indian seas. The Linnæan name of this fish is supposed to have been given from its tortoise-like beak, but perhaps, with more propriety, from its variegated skin.

4. Tetrodon ocellatus, ocellated tetrodon. Length six or eight inches: shape thick, ovate, contracting suddenly towards the tail; mouth slightly produced: colour deep-green above, gradually growing paler on the sides and abdomen, which are whitish. Native of the Indian seas, and sometimes of the adjoining rivers, particularly those of China and Japan. It is of an extremely poisonous nature, if eaten without the greatest care in properly cleaning it before dressing, and is said sometimes to have proved fatal in the short space of two hours. The symptoms, according to Rumphius, may be cured by the timely administration of a vegetable which he calls rex amaroris. The emperor of Japan prohibits his soldiers, under very severe penalties, from eating this fish: the rest of his subjects may, as Mr. Pennant observes, run the risk of being poisoned with impunity.

TEUCRIUM, *germander*, a genus of plants of the class didynamia, and order gymnospermia; and in the natural system ranging under the 42d order, verticillatæ. The corolla has the upper lip divided into two parts beyond the base, and divaricated where the stamina issue out. There are 69 species, of which the scorodonia, scordium, and chamædrys, are natives of Great Britain. 1. The scorodonia, wood sage, or germander, is distinguished by leaves which are heart-shaped, serrated, and petiolated; by racemi, which are lateral and ranged in one row; and by an erect stem. The flowers are straw-coloured, and the filaments red. The plant has a bitter taste, and smells like hops with a little mixture of garlic. It is used in brewing in the isle of Jersey instead of hops. 2. The scordium, or common water-germander, has creeping perennial roots, sending up many square, procumbent, or trailing stalks, branching diffusely, and small reddish flowers. This plant was formerly considered as medicinal, but has now fallen into disuse. It grows naturally in marshy places, in the isle of Ely and other parts of England, and most parts of Europe; and is sometimes admitted into gardens, in moist places, for variety, and as a medical plant. 3. The chamædrys, or smaller creeping germander, has reddish flowers, growing almost in a verticillus, or whorls, round the stalk, three on each peduncle: appearing in June and July. There are also some foreign species, ornamental as greenhouse plants.

TEUTHIS, a genus of fishes of the abdominal order. The generic character is, head truncate on the fore part; gill-membrane five-rayed; teeth equal, rigid, approximate in a single row. There are two species, 1. The hepatus, that inhabits Carolina and Amboina. 2. The jarva, that takes its name from the place where it is found.

TEUTONIC ORDER, a military order of kights, established towards the close of the twelfth century, and thus called as consisting chiefly of Germans or Teutons. The origin, &c. of the Teutonic order is said to be this: The Christians, under Guy of Lusignan, laying siege to Acre, a city of Syria, on the borders of the Holy Land, some Germans of Bremen and Lubec, touched with compassion for the sick and wounded of the army, who wanted common necessaries, set on foot a kind of hospital under a tent, which they made of a ship's sail, and here betook themselves to a charitable attendance on them. This excited a thought of establishing a third military order, in imitation of the templars and hospitalers. The design was approved of by the patriarch of Jerusalem, the archbishops and bishops of the neighbouring places, the king of Jerusalem, the masters of the temple and hospital, and the German lords and prelates then in the Holy Land, and pope Calixtus III. confirmed it by his bull, and the new order was called the order of Teutonic knights of the house of St. Mary at Jerusalem. The pope granted them all the privileges of the templars and hospitalers of St. John, excepting that they were to be subject to the patriarchs and other prelates, and that they should pay tythe of what they possessed. The officers of the Teutonic order, while in its splendour, were the grand master, who resided at Marienburg; under him were the grand commander; the grand marshal, who had his residence at Koningsberg; the grand hospitaler, who resided at Elbing; the draper, who took care to furnish the habits; the treasurer, who lived at the court of the grand master; and several commanders, as those of Thorn, Culme, Brandenburg, Koningsberg, Elbing, &c. They had also their commanders of particular castles and fortresses, advocates, proveditors, intendants of mills, provisions, &c. This order is now little more than the shadow of what it formerly was, having only three or four commanderies, scarcely sufficient for the ordinary subsistence of the grand master and his knights.

THALIA, a genus of plants of the class monandria, and order monogynia; and in the natural system ranging under the eighth order, scitamineæ. The corolla is pentapetalous and undulated; and the drupe has a unilocular kernel. There are two species, the geniculata and cannæformis.

THALICTRUM, *meadow rue*, a genus of plants of the class polyandria, and order polygynia; and in the natural system ranging under the 26th order, multisiliquæ. There is no calyx; the petals are four or five in number, and the seeds are naked and without a tail. There are 22 species; three of which are indigenous, the flavum, minus, and alpinum. 1. The flavum, or common meadow-rue, has a leafy furrowed stalk, and a manifold erect panicle. It has commonly 24 stamina, and from ten to sixteen pistils. The root and leaves of this plant dye a yellow colour, and cattle are fond of it. It grows on the banks of some rivers. 2. The minus, or small meadow-rue, has sexpartite leaves, and bending flowers. This plant is frequent in sandy soils and mountainous pastures. 3. The alpinum, or alpine meadow-rue, has a very simple stalk, and almost naked; and a racemus simple and terminal. It is frequent on the sides of rivulets.

THALLITE, a stone found in the fissures of mountains in Dauphiny, and of Chamouni, in the Alps. It is sometimes amorphous, and sometimes crystallized. The primitive form of its crystals is a rectangular prism, whose bases are rhombs with angles of 114° 37′, and 65° 23′. The most usual variety is an elongated four-sided prism (often flattened), terminated by four-sided incomplete pyramids; sometimes it occurs in regular six-sided prisms. The crystals are often very slender.

Its texture appears fibrous. Lustre 2. Glassy. Causes single refraction. Brittle. Specific gravity 3.45 to 3.46. Colour dark green. Powder white or yellowish green, and feels dry. It does not become electric by heat. Before the blowpipe, froths, and melts into a black slag. With borax melts into a green bead.

A specimen of thallite, analysed by Mr. Descotils, contained

37	silica
27	alumina
17	oxide of iron
14	lime
1.5	oxide of manganese
96.5	

THASPIA, the deadly carrot, a genus of plants of the class pentandria, and order diynia; and in the natural system ranging under the 45th order, umbellatæ. The fruit is oblong, and girt with a membrane. There are six species; the villosa, fœtida, asclepium, garganica, trifoliata, and polygami. The roots of the fœtida were formerly ordered in medicine, but are now entirely disused; a small dose operating with extreme violence both upwards and downwards.

THEA, the tea-tree, in botany, a genus of the class and order polyandria monogynia. The corolla is six or nine-petalled; the calyx five or six-leaved; the capsule tricoccous. There are two species, or at least principal varieties; the viridis or green, and the bohea, which again admit of various subdivisions or varieties. There is, however, much uncertainty on this point. The country of which the tea plant is a native, is hidden from the exploring eye of the philosopher; it is jealous of Europeans, and seldom gives them an opportunity of studying its productions.

The tea plant is a native of Japan, China, and Tonquin, and has not, as far as we can learn, been found growing spontaneously in any other part of the world. Sir Charles Thunberg, one of the most distinguished pupils of Linnæus, who resided sixteen months in Batavia and Japan, has given a full botanical description of the tea plant; and having classed it in the same manner as his master, says expressly that it has only one style. Several of the British botanists, on the other hand, refer it to the order of trigynia; deriving their authority from a plant in the duke of Northumberland's garden at Sionhouse, which had three styles.

Linnæus says that there are two species of the tea plant; the bohea, the corolla of which has six petals; and the viridis, or green tea, which has nine petals. Thunberg makes only one species, the bohea, consisting of two varieties: the one with broad and the other with narrow leaves. This botanist's authority is decisive respecting the Japanese tea plants; but as China has not yet been explored, we cannot determine what number of species there are in that country. The tea-tree, however, is now common in the botanical gardens in this country; and it is evident that there are two species, or, at least, permanent varieties of it: one with a much longer leaf than the other, which our gardeners call the green tea; and the other with shorter leaves, which they call the bohea. The green is by much the hardiest plant, and with very little protection will bear the rigour of our winters. Messrs. Loddridges, of Hackney, have now several large plants of it in the open ground, which they only cover with mats in hard frost. It is chiefly propagated in this country by layers. See Plate Nat. Hist. fig. 400.

This plant delights in valleys, and is frequent on the sloping sides of mountains and the banks of rivers, where it enjoys a southern exposure. It flourishes in the northern latitudes of Pekin as well as round Canton; but attains the greatest perfection in the mild temperate regions of Nankin. It is said only to be found between the 30th and 45th degree of north latitude. In Japan it is planted round the borders of fields, without regard to the soil; but as it is an important article of commerce with the Chinese, whole fields are covered with it, and it is by them cultivated with care. The abbé Rochen says, it grows equally well in a poor as in a rich soil; but that there are certain places where it is of a better quality. The tea which grows in rocky ground is superior to that which grows in a light soil; and the worst kind is that which is produced in a clay soil. It is propagated by seeds; from six to twelve are put into a hole about five inches deep, at certain distances from each other. The reason why so many seeds are sown in the same hole is said to be, that only a fifth part vegetate. Being thus sown, they grow without any other care. Some, however, manure the land, and remove the weeds; for the Chinese are as fond of good tea, and take as much pains to procure it of an excellent quality, as the Europeans do to procure excellent wine.

The leaves are not fit for being plucked till the shrub is of three years' growth. In seven years it rises to a man's height; but as it then bears but few leaves, it is cut down to the stem, and this produces a new crop of fresh shoots the following summer, every one of which bears nearly as many leaves as a whole shrub. Sometimes the plants are not cut down till they are ten years old. We are informed by Kæmpfer, that there are three seasons in which the leaves are collected in the isles of Japan, from which the tea derives different degrees of perfection.

The first gathering commences at the end of February or beginning of March. The leaves are then small, tender, and unfolded, and not above three or four days old: these are called ficki-tsiaa, or "tea in powder," because it is pulverised; it is also called imperial tea, being generally reserved for the court and people of rank; and sometimes also it is named bloom tea. It is sold in China for 20*d.* or 2*s.* per pound. The labourers employed in collecting it do not pull the leaves by handfuls, but pick them up one by one, and take every precaution that they may not break them. However long and tedious this labour may appear, they gather from four to ten or fifteen pounds a day.

The second crop is gathered about the end of March or beginning of April. At this season part of their leaves have attained their full growth, and the rest are not above half their size. This difference does not, however, prevent them from being all gathered indiscriminately. They are afterwards picked and assorted into different parcels, according to their age and size. The youngest, which are carefully separated from the rest, are often sold for leaves of the first crops, or for imperial tea. Tea gathered at this season is called too-tsiaa, or "Chinese tea," because the people of Japan infuse it, and drink it after the Chinese manner.

The third crop is gathered in the end of May, or in the month of June. The leaves are then very numerous and thick, and have acquired their full growth. This kind of tea, which is called ben-tsiaa, is the coarsest of all, and is reserved for the common people. Some of the Japanese collect their tea only at two seasons of the year, which correspond to the second and third already mentioned: others confine themselves to one general gathering of their crop, towards the month of June: however, they always form afterwards different assortments of their leaves.

An infusion of tea is the common drink of the Chinese; and indeed, when we consider one circumstance in their situation, we must acknowledge that Providence has displayed much goodness in scattering this plant with so much profusion in the empire of China. The water is said to be unwholesome and nauseous, and would therefore, perhaps, without some corrective, be unfit for the purposes of life. The Chinese pour boiling water over their tea, and leave it to infuse, as we do in Europe; but they drink it without any mixture, and even without sugar. The people of Japan reduce theirs to a fine powder, which they dilute with warm water until it has acquired the consistence of thin soup. Their manner of serving tea is as follows: They place before the company the tea-equipage, and the box in which this powder is contained; they fill the cups with warm water, and taking from the box as much powder as the point of a knife can contain, throw it into each of the cups, and stir it with a tooth-pick until the liquor begins to foam; it is then presented to the company, who sip it while it is warm. According to Du Halde, this method is not peculiar to the Japanese; it is also used in some of the provinces of China.

The first European writer who mentions tea is Giovanni Botero, an eminent Italian author, who published a treatise about the year 1590, of the causes of the magnificence and greatness of cities. He does not indeed mention its name, but describes it in such a manner that it is impossible to mistake it. "The Chinese (says he) have a herb out of which they press a delicate juice, which serves them for drink instead of wine; it also preserves their health, and frees them from all those evils which the immoderate use of wine produces among us."

Tea was introduced into Europe in the year 1610 by the Dutch East India company. It is generally said, that it was first imported from Holland into England, in 1666, by the lords Arlington and Ossory, who brought it into fashion among people of quality. But it was used in coffee-houses before this period, as appears from an act of parliament made in 1660, in which a duty of 8*d.* was laid on every gallon of the infusion sold in these places. In 1666 it was sold in London for 60*s.* per pound, though it did not cost more than 2*s.* 6*d.* or 3*s.* 6*d.* at Batavia. It continued at this price till 1707. In 1715 green tea began to be used; and as great quantities were then imported, the price was lessened, and the practice of drinking tea descended to the lower ranks. In 1720 the French began to send it to us by a clandestine commerce. Since that period the demand has been increasing yearly, and it has become almost a necessary of life in several parts of Europe, and among the lowest as well as the highest ranks:

The following table will give an idea of the quantity of tea imported annually into Great Britain and Ireland since 1717:

From	1717 to 1726	-	700,000 lb.
	1732 to 1742	-	1,200,000
	1755 near	-	4,000,000
	1766	-	6,000,000
	1785 about	-	12,000,000
	1794 from		16 to 20,000,000

Besides these immense quantities imported into Britain and Ireland, much has been brought to Europe by other nations. In

1766 the whole tea imported into Europe from China amounted to 17 millions of pounds; in 1785 it was computed to be about 19 millions of pounds.

In this country teas are generally divided into three kinds of green, and five of bohea: the former are, 1. Imperial or bloom tea, with a large loose leaf, light-green colour, and a faint delicate smell. 2. Hyson, so called from the name of the merchant who first imported it; the leaves of which are closely curled and small, of a green colour, verging to a blue: 3. Singlo tea, from the name of the place where it is cultivated. The boheas are, 1. Souchong, which imparts a yellow-green colour by infusion. 2. Camho, so called from the place where it is made; a fragrant tea, with a violet smell; its infusion pale. 3. Congo, which has a larger leaf than the preceding, and its infusion somewhat deeper, resembling common bohea in the colour of the leaf. 4. Pekoe tea; this is known by the appearance of small white flowers mixed with it. 5. Common bohea, whose leaves are of one colour. There are other varieties, particularly a kind of green tea, done up in roundish balls, called gunpowder tea.

THEATINES, a religious order in the Romish church, so called from their principal founder John Peter Caraffa, then bishop of Theate, or Chieti, in the kingdom of Naples, and afterwards pope, under the name of Paul IV.

THEFT, in law, an unlawful felonious taking away another man's moveable and personal goods, against the owner's will, with intent to steal them. It is divided into theft or larceny, properly so called, and petit theft, or petit larceny; the former whereof is of goods above the value of 12*d.* and is deemed felony; the other, which is of goods under that value, is not felony. See the articles FELONY and LARCENY.

THEFTBOTE, the receiving a man's goods again from a thief, or other amends, by way of composition, and to prevent prosecution, that the felon may escape unpunished; the punishment whereof is fine and imprisonment.

THELIGONUM, a genus of plants of the class monœcia, and order polyandria; and in the natural system ranging under the 53d order, scabridæ. The male calyx is bifid; there is no corolla; the stamina are generally 12. The female calyx is also bifid; there is no corolla; only one pistil; the capsule is coriaceous unilocular, and monospermous. There is only one species, the cynocrambe, which is indigenous in the south of Europe.

THEOBROMA, a genus of plants of the class polyadelphia, and order decandria; and in the natural system ranging under the 37th order, columniferæ. The calyx is triphyllous; the petals, which are five in number, are vaulted and two-horned; the nectarium is pentaphyllous and regular; the stamina grow from the nectarium, each having five antheræ, see Plate Nat. Hist. fig. 402. There is one species, viz.

The cacao, or chocolate-tree, which we shall describe in the words of Dr. Wright: "In all the French and Spanish islands and settlements in the warmer parts of America, the chocolate-tree is carefully cultivated. This was formerly the case also in Jamaica but at present we have only a few straggling trees left as monuments of our indolence and bad policy. This tree delights in shady places and deep valleys. It is seldom above 20 feet high. The leaves are oblong, large, and pointed. The flowers spring from the trunk and large branches; they are small, and pale red. The pods are oval and pointed. The seeds or nuts are numerous, and curiously stowed in a white pithy substance. The cocoa-nuts being gently parched in an iron pot over the fire, the external covering separates easily. The kernel is levigated on a smooth stone; a little arnotto is added, and with a few drops of water is reduced to a mass, and formed into rolls of one pound each. This simple preparation of chocolate is the most natural, and the best. It is in daily use in most families in Jamaica, and seems well adapted for rearing of children."

THEODOLITE, a mathematical instrument much used in surveying, for the taking of angles, distances, &c.

It is made variously, several persons having their several ways of contriving it, each supposed to be more simple and portable, or more accurate and expeditious, than others.

The following is a description of one of the most useful, and for a more particular account of some of its peculiar parts we refer to the article LEVEL: The three staves, see Plate Miscel. fig. 236, whereby it is supported, screw into bell-metal joints by brass ferules at top, which are moveable between brass pillars fixed in a strong brass plate; in which, round the centre, is fixed a socket with a ball moveable in it, and upon which the four screws press that set the limb horizontal. Next above is such another plate, through which the said screws pass, and on which round the centre is fixed a frustum of a cone of bell-metal, whose axis, being connected with the centre of the ball, is always perpendicular to the limb, by means of a conical brass ferule fitted to it, whereon is fixed the compass-box, and on it the limb, which is a strong bell-metal ring, whereon are moveable three brass indexes, in whose plate are fixed four brass pillars, that joining at top, hold the centre-pin of the bell-metal double sextant, whose double index is fixed in the centre of the same plate. Within the double sextant is fixed the spirit level, and over it the telescope.

The telescope is a little shorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much, and shew a distinct object as perfect, as most of treble its length: in its focus are very fine cross wires, whose intersection is in the plane of the double sextant; this was a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; so that whenever the limb is set horizontal (which is readily done by making the spirit-tube level over two screws, and the like over the other two) the double sextant and telescope are moveable in a vertical plane, and then every angle taken on the limb (though the telescope is never so much elevated or depressed) will be an angle in the plane of the horizon, and this is absolutely necessary in plotting an horizontal plane.

THEOPHRASTA, in botany, a genus of the pentandria monogynia class of plants, with a monopetalous campanulated petal, semiquinquefid at the limb: the fruit is a large, globose, unilocular capsule, containing a great many roundish seeds. There are two species, shrubs of the West Indies.

THEOREM, a proposition which terminates in theory, and which considers the properties of things already made or done. Or a theorem is a speculative proposition, deduced from several definitions compared together. Thus, if a triangle is compared with a parallelogram standing on the same base, and of the same altitude; and partly from their immediate definitions, and partly from other of their properties already determined, it is inferred that the parallelogram is double the triangle; that proposition is a theorem.

Theorem stands contradistinguished from problem, which denotes something to be done or constructed, as a theorem proposes something to be proved or demonstrated.

There are two things to be chiefly regarded in every theorem, viz. the proposition and the demonstration. In the first is expressed what agrees to some certain thing, under certain conditions, and what does not. In the latter, the reasons are laid down by which the understanding comes to conceive that it does or does not agree to it.

Theorems are of various kinds; as,

Universal theorem, is that which extends to any quantity without restriction, universally, as this; that the rectangle or product of the sum and difference of any two quantities, is equal to the difference of their squares.

Particular theorem, is that which extends only to a particular quantity, as this; in an equilateral rectilinear triangle, each angle is equal to 60 degrees.

Negative theorem, is that which expresses the impossibility of any assertion, as that the sum of two biquadrate numbers cannot make a square number.

Local theorem, is that which relates to a surface, as that triangles of the same base and altitude are equal.

Plane theorem, is that which relates to a surface that is either rectilinear, or bounded by the circumference of a circle; as that all angles in the same segment of a circle are equal.

Solid theorem, is that which considers a space terminated by a solid line; that is, by any of the three conic sections; as this: that if a right line cuts two asymptotic parabolas, its two parts terminated by them shall be equal.

Reciprocal theorem, is one whose converse is true; as that if a triangle has two sides equal, it has also two angles equal: the converse of which is likewise true, viz. that if the triangle has two angles equal, it has also two equal sides.

THERMOMETER. A glass vessel filled to a certain degree with a liquid, for the purpose of shewing the expansions of that liquid in different temperatures, or for the purpose of shewing the temperature by the corresponding expansion of that liquid, is called a thermometer; *i. e.* a measure of the temperature.

The fluids mostly used for thermometers, are either mercury or spirit of wine; the latter of which is generally tinged red, by means of cochineal, or Brazil wood, &c. for the purpose of rendering it more visible; hence they are denominated the mercurial thermometer, and the spirit thermometer. Other fluids, on account of their clamminess, or of their great irregularity of expansion, are not useful for thermometers.

The most proper and the most useful shape for thermometers, is that of a long tube with a narrow bore, and with a globular cavity at one extremity (see Plate Miscel. fig. 237.). The cavity of the bulb C, and part of the tube, as far, for instance, as A, are filled with the fluid: the rest of the tube is either partly, or quite, exhausted of air; and the end B of the tube is hermetically sealed; viz. perfectly closed by melting the extremity of the tube at the flame of a candle or lamp, urged by means of a blowpipe.

When the bulb C is heated, the mercury, or the spirit of wine, is expanded; and not being able to extend itself any other way, all the increment of bulk is manifested in the tube, viz. the surface A of the fluid will rise considerably into the tube. On the other hand, when the bulb C is cooled, the fluid contracts, and its surface A descends. It is evident, that, cæteris paribus, the larger the bulb is, in proportion to the diameter of the cavity of the tube, or the narrower the latter is in proportion to the former, the greater will the motion of the surface A be in the tube. But it must be observed, that when the bulb is very large, the thermometer will not easily arrive at the precise temperature of any place, wherein it may be situated. Some persons, in order to give the bulb a greater surface, and of course to render it more capable of readily attaining a given temperature, have made it not globular, but cylindrical (which shape was adopted by Fahrenheit), or flat, or bell-like, &c.; but those shapes are improper, because they are liable to be altered by the varying gravity of the atmosphere, consequently those thermometers cannot be accurate.

If a thermometer is heated suddenly, as when the bulb C is immerged in hot water, the surface A of the fluid in it will be seen to descend a little, and instantly after will be seen to rise; the reason of which is, that the heat of the water enlarges the glass first, and is then communicated to the fluid, &c. On the contrary, if the bulb of a thermometer is cooled suddenly, the surface A of the fluid will first rise a little, and then will descend; because the cold contracts the glass alone at first, and afterwards contracts the fluid.

Ice is melted by a certain invariable degree of temperature; and water freezes at about the same temperature; therefore, if the bulb C of a mercurial thermometer is placed in melting ice, or melting snow, and a mark is made on the outside of the tube, even with the surface of the fluid, as at D; that mark is called the freezing-point, though in fact it is the melting-point of ice; the freezing-point of water being not so constant. If the bulb of the thermometer is placed in boiling water, and a mark is made on the glass tube, even with the surface of the fluid within, as at E, that mark is called the boiling-point; for in an open vessel, and under the same atmospherical pressure, which is indicated by the barometer, water constantly boils at the same temperature, and an increased fire will force it to evaporate faster, but will not raise its temperature. Those points being ascertained, if the length of the tube from D to E is divided into any number of equal parts, those parts will be the degrees of the thermometer, or the degrees of heat, indicated by the corresponding expansions of the fluid within the thermometer. And the same degrees, or equal divisions, may be continued below D and above E, in order to shew the degrees of temperature below the freezing, and above the boiling, point.

Those two unalterable points of temperature, viz. the former where ice becomes water, and the second where water becomes vapour, have been universally adopted by the various constructors of thermometers for the graduation of those instruments; but the space between them has been divided differently by different persons, and this difference gives the different names of thermometers, or rather of their graduations; such as Reaumur's thermometer, Fahrenheit's thermometer, &c. Reaumur divides the space between the abovementioned two points, into 80 equal parts or degrees; placing the 0 at freezing, and the 80th degree at the boiling point. Fahrenheit divides it into 180 degrees or equal parts, but he places the 0 thirty-two degrees below the freezing-point D; so that the freezing-point is at 32, and the boiling-point E is at 212 degrees.

Other persons have adopted other divisions, which have been suggested by supposed advantages or fanciful ideas.

Most of those graduations are at present out of use, but they are to be met with in various, not very recent, publications; we have therefore thought it necessary to set them down in the following table, which contains: 1st. The name of the person or society that has used each particular division; 2dly. The degree which has been placed, by each of them, against the freezing-point; 3dly. The degree which has been placed against the boiling-point; and, 4thly. The number of degrees lying between those two points.

	Freezing-point.	Boiling-point.	Deg. between the preceding two points.
Fahrenheit's, which is generally used in Great Britain. It is also used throughout this work, unless some other is mentioned - - -	32	212	180
Reaumur's, which is generally used in France and other parts of the Continent - -	0	80	80
Celsius's, which has been used chiefly in Sweden, hence it is also called the Swedish thermometer. It has been lately adopted by the French chemists, under the name of centigrade thermometer	0	100	100
The Florentine thermometers, which were made and used by the members of the famous academy *del' Cimento*, being some of the first instruments of the sort, were vaguely graduated, some having a great many more degrees than others. But two of their most common graduations seem to be	20	174	154
	$13\frac{1}{2}$	$81\frac{2}{3}$	$68\frac{1}{6}$
The Parisian thermometer, viz. the *ancienne thermometre* of the Academy of Sciences, seems to have been graduated nearly thus, - -	25	239	214
De la Hire's thermometer, which stood in the observatory at Paris above 60 years, was graduated thus, - -	28	$199\frac{1}{3}$	$171\frac{1}{3}$
Amanton's - -	$51\frac{1}{2}$	73	$21\frac{1}{2}$
Poleni's - - -	$47\frac{3}{10}$	$62\frac{9}{10}$	$15\frac{6}{10}$
De L'Isle's thermometer is graduated in an inverted order - -	150	0	150
Sir Isaac Newton's -	0	34	34
Hales's - - -	0	163	163
The Edinburgh thermometer, formerly used, seems to have been graduated thus, - -	$8\frac{1}{5}$	47	$38\frac{4}{5}$

These are the chief thermometers that have been used in Europe; and the temperatures indicated by the principal of them may be reduced into the corresponding degrees on any of the others, by means of the following simple theorems; in which R signifies the degrees on the scale of Reaumur, F those of Fahrenheit, and S those of the Swedish thermometer.

1. To convert the degrees of Reaumur into those of Fahrenheit; $\frac{R \times 9}{4} + 32 = F$.

2. To convert the degrees of Fahrenheit into those of Reaumur; $\frac{(F - 32) \times 4}{9} = R$.

3. To convert the Swedish degrees into those of Fahrenheit; $\frac{S \times 9}{5} + 32 = F$.

4. To convert Fahrenheit's into Swedish; $\frac{(F - 32) \times 5}{9} = S$.

5. To convert Swedish degrees into those of Reaumur; $\frac{S \times 4}{5} = R$.

6. To convert Reaumur's degrees into Swedish; $\frac{R \times 5}{4} = S$.

To such readers as are unacquainted with the algebraic expression of arithmetical formulæ, it will be sufficient to express one or two of these in words, to explain their use: 1. Multiply the degree of Reaumur by 9, divide the product by 4, and to the quotient add 32, the sum expresses the degree on the scale of Fahrenheit. 2. From the degree of Fahrenheit subtract 32, multiply the remainder by 4, and divide the product by 9, the quotient is the degree according to the scale of Reaumur, &c.

Thermometers have been made of a great variety of shapes and sizes, suitable to the different purposes for which they were intended.

Thermometers for shewing the temperature of the atmosphere, need not have their scales much extended; it is more than sufficient if they go as high as 120°. The lower degrees may be carried down as low as may be necessary for the cold of any particular climate. The mercurial thermometer needs not to be graduated lower than 40° below 0, because at about that degree mercury ceases to be a fluid.

The spirit thermometer may be graduated lower if necessary. We shall here just mention, that, for reasons which will be noticed hereafter, if a mercurial thermometer and a spirit thermometer are both graduated according to the above-mentioned directions, the two thermometers will not, in their usual indications of the same temperatures, point to the same degrees.

The degrees of thermometers may be delineated on metal, or wood, or paper, or ivory, &c. but such substances should be preferred for the scales of thermometers, as are not apt to be bent or shortened, or otherwise altered by the weather, especially when the instruments are not defended by a glass case, or by a box with a glass face.

The bulb of the thermometer must be clean and colourless; since coloured surfaces are apt to be partially heated by a strong light. The ball of the thermometer ought not to be in contact with the substance of the scale, lest it should be influenced by the temperature of that substance.

Thermometers which are to be situated in the open air out of the house, must be at some distance (at least a foot) from the wall, and where the light of the sun may not fall directly upon them. Fig. 238 represents a thermometer of the most usual shape independant of the case.

For chemical purposes, the bulb and part of the tube of the thermometer, must project some way below the scales, in order that they may be placed in liquids, mixtures, &c.

For other purposes, as for botanical observations, hot-houses, brewing-manufactories, baths, &c. the thermometers must be made longer, or shorter, or narrower, or particular directions must be added to the scales, &c.; but we shall not take any farther notice of those fluctuating varieties of shape only.

It is necessary, however, to describe a sort of thermometers which have been constructed for a particular purpose; namely, for shewing the highest degree of heat or of cold which has taken place during the absence of the observer; as for instance, in the course of the night, or in the hottest part of the day, or even during a whole season.

Thermometers for this purpose have been contrived differently by various ingenious persons, as by Bernouilli, Kroft, lord Charles Cavendish, &c. but the best of them, which however is not without faults, and of course is in need of improvements, was contrived by Mr. James Six, and is described in the 72nd vol. of the Philosophical Transactions. Fig. 239 exhibits this instrument, but divested of the scale and frame; *ab* is a tube of thin glass, about 16 inches long, and $\frac{5}{16}$ of an inch in diameter; *cdefgh*, a smaller tube with the inner diameter, about $\frac{1}{40}$, joined to the larger at the upper end *b*, and bent down, first on the left side, and then, after descending two inches below *ab*, upwards again on the right, in the several directions *cde*, *fgh*, parallel to, and one inch distant from it. On the end of the same tube at *h*, the inner diameter is enlarged to half an inch from *h* to *i*, which is two inches in length. This glass is filled with highly rectified spirit of wine, to within half an inch of the end *i*, excepting that part of the small tube from *d* to *g*, which is filled with mercury. From a view of the instrument in this state, it will readily be conceived, that when the spirit in the large tube, which is the bulb of the thermometer, is expanded by heat, the mercury in the small tube on the left side will be pressed down, and consequently cause that on the right side to rise; on the contrary, when the spirit is condensed by cold, the reverse will happen, the mercury on the left side will rise as that on the right side descends. The scale, therefore, which is Fahrenheit's, beginning with 0, at the top of the left side, has the degrees numbered downwards, while that at the right side, beginning with 0 at the bottom, ascends. The divisions are ascertained, by placing this thermometer with a good standard mercurial one in water, gradually heating or cooling, and marking the divisions of the new scale at every 5°. The method of shewing how high the mercury had risen in the observer's absence, is effected in the following manner: Within the small tube of the thermometer, above the surface of the mercury on either side, immersed in the spirit of wine, is placed a small index, so fitted as to pass up and down as occasion may require; that surface of the mercury which rises, carries up the index with it, which index does not return with the mercury when it descends; but, by remaining fixed, shews distinctly, and very accurately, how high the mercury had risen, and consequently what degree of heat or cold had happened. Fig. 240 represents these indexes drawn larger than the real ones, to render it more distinct; *a* is a small glass tube $\frac{3}{4}$ of an inch long, hermetically sealed at each end, inclosing a piece of steel wire, nearly of the same length; at each end *c d*, is fixed a short piece of a tube of black glass, of such a diameter as to pass freely up and down within the small tube of the thermometer. The lower end, floating on the surface of the mercury, is carried up with it when it rises; while the piece at the upper end, being of the same diameter, keeps the body of the index parallel to the sides of the thermometrical tube. From the upper end of the body of the index at 0, is drawn a spring of glass to the fineness of a hair, about $\frac{2}{3}$ of an inch in length, which being set a little oblique, presses lightly against the inner surface of the tube, and prevents the index from following the mercury when it descends, or being moved by the spirit passing up or down, or by any sudden motion given to the instrument by the hand or otherwise; but at the same time the pressure is so adjusted, as to permit this index to be readily carried up by the surface of the rising mercury, and downwards whenever the instrument is to be rectified for observation. To prevent the spirit from evaporating, the tube at the end *i* is closely sealed.

This instrument in its frame must be secured against the wall out of doors, to prevent its being shaken by violent winds. "Towards evening," says Mr. Six, "I usually visit my thermometer, and see at one view, by the index on the left side, the cold of the preceding night; and by that on the right, the heat of the day. These I minute down, and then apply a small magnet to that part of the tube against which the indexes rest, and move each of them down to the surface of the mercury; thus, without heating, cooling, separating, or at all disturbing the mercury, or moving the instrument, may this thermometer, without a touch, be immediately rectified for another observation."

The common contrivance for a self-registering thermometer, now sold in most of the London shops, consists simply of two thermometers, one mercurial and the other of alcohol (fig. 243), having their stems horizontal; the former has for its index a small bit of magnetical steel wire, and the latter a minute thread of glass, having its two ends formed into small knobs by fusion in the flame of a candle.

The magnetical bit of wire lies in the vacant space of the mercurial thermometer, and is pushed forward by the mercury whenever the temperature rises, and pushes that fluid against it; but when the temperature falls and the fluid retires, this index is left behind, and consequently shews the maximum. The other index, or bit of glass, lies in the tube of the spirit thermometer immersed in the alcohol; and when the spirit retires by depression of temperature, the index is carried along with it in apparent contact with its interior surface; but on increase of temperature the spirit goes forward and leaves the index, which therefore shews the minimum of temperature since it was set. As these indexes merely lie in the tubes, their resistance to motion is altogether inconsiderable. The steel index is brought to the mercury by applying a magnet on the outside of the tube, and the other is duly placed at the end of the column of alcohol by inclining the whole instrument.

The operation of this instrument has been thus explained: When the surface of the column of spirit is viewed by a magnifier, it is seen to have the form of a concave hemisphere, which shews that the liquid is attracted by the glass. The glass in that place is consequently attracted in the opposite direction, by a force equal to that which is so employed in maintaining that concave figure; and if it was at liberty to move, it would be drawn back till the flat surface was restored. Let us suppose a small stick or piece of glass to be loose within the tube, and to protrude into the vacant space beyond the surface of the alcohol. The fluid will be attracted also by the glass, and form a concave between its surface, and that of the bore of the tube. But the small interior piece being quite at liberty to move, will be drawn towards the spirit so long as the attractive force possesses any activity; that is, so long as any additional fluid hangs round the glass; or, in other words, until the end of the stick of glass is even with the surface. Whence it is seen that the small piece of glass will be resisted, in any action that may tend to protrude it beyond the surface of the fluid; and if this resistance is greater than the force required to slide it along in the tube (as in fact it is), the piece must be slided along as the alcohol contracts; so as always to keep the piece within the fluid. And this fact is accordingly observed to take place.

It might at first sight be imagined that equal increments of heat would cause fluids to expand equably; viz. that if the heat is increased gradually by one degree, two degrees, three degrees, &c. the fluid thus heated would expand its bulk by a certain quantity, then by twice that quantity, three times that quantity, and so on. But this is not the case, and every fluid seems to follow a particular law of expansion.

Mercury seems to expand more equably than any other fluid. Yet its increments of bulk are not quite proportional to the increments of heat. With other fluids the irregularity of expansion is very considerable.

One cubic inch of mercury, or one measure whatever of it, at 32° of temperature, when heated to the temperature of boiling water, viz. at 212°, will be found increased in bulk by the quantity 0.01836. This fluid metal boils and becomes a vapour at 600° of Fahrenheit's thermometer, and it becomes a solid at — 40°; viz. 72° below melting ice. Below that point, viz. — 40°, it contracts irregularly.

Spirit of wine boils at about 180° and the purest probably never freezes. When brandy, or a mixture of water and spirit, freezes, it is the water that becomes solid, but the spirit will be found collected together in one or more bubbles, in some part of the ice.

From all that has been said with respect to the expansion of fluids, it appears that, on account of the great irregularity of the rate of expansion, mercury and spirit of wine are the only two fluids which can be used for thermometers; observing that some compensation must be made in the scale of the spirit thermometer, in order to make it correspond with the scale of the mercurial thermometer. But the mercurial thermometer cannot indicate a temperature higher than 600. Hence various ingenious persons have endeavoured to contrive instruments capable of indicating the higher degrees of heat, which would be of great use in philosophy, chemistry, and various arts; but the only useful contrivance of this sort was made by the late Mr. Wedgewood. This ingenious gentleman applied to the measuring of high degrees of heat, a singular property of argillaceous bodies, a property which obtains more or less in every kind of them, as far as has been examined. This property is, that an argillaceous substance, when exposed to fire, is diminished in bulk by it, nor does the bulk increase again after cooling; and this diminution of bulk is proportionate to the degree of heat to which the substance has been exposed.

This property may seem to be a deviation from the general rule, viz. that heat expands all sorts of bodies, and that a diminution of heat enables them to contract their dimensions; but in this case it must be considered that the clay pieces contract and remain contracted, because some substance, viz. water and an aëriform fluid, is separated from them by the action of the fire.

Mr. Wedgewood's thermometer, or apparatus for measuring the high degrees of heat, consists of small pieces of clay of a determined length, which are to be placed in the furnace, crucible, &c. whose degree of heat is to be ascertained; and of a gauge to measure the contracted dimensions of the clay pieces, after they have been exposed to the fire.

Fig. 241 represents the gauge, which is either of brass or of porcelain. Fig. 242 represents a section of the same; and the letters refer to the like parts in both figures. EFGH is a smooth flat plate; AC, BD, are two rulers or flat pieces, a quarter of an inch thick, and fixed fast upon the plate, so as to form a converging canal ABCD, whose width at CD is three-fifths of the width at AB. The whole length of the canal from AB to CD, is divided into 240 equal parts, and the divisions are numbered from the wider end. It is evident that if a body, so adjusted as to fit exactly the wider end of this canal, is afterwards diminished in its bulk by the action of fire (as the thermometrical pieces which will be described in the next paragraph), it may then be passed further in the canal, and more so according as the diminution is greater.

The thermometrical pieces are small cylinders of clay, a little flattened on one side. They are nearly as much in diameter as they are in length. When one of these pieces is to be used, it is proper to measure it first by placing it in the gauge at AB; for sometimes the pieces are a few degrees larger or smaller than the distance AB, which excess or defect being ascertained, must afterwards be allowed for. P represents one of these pieces set in the gauge for measurement.

The piece is then placed in the furnace, or crucible; and if it is taken out either at the end of the operation, or at any period, and, when grown cold, is measured by sliding it as far as it will go, into the canal of the gauge, the number of divisions against the place where it stops will shew the contracted dimensions of the piece, and of course the degree of heat to which it has been exposed. It will be found that these pieces will go very little beyond 0 in the canal, if they have been exposed to a visible red heat; will go to 27° if they have been exposed to the heat in which copper melts; to about 90° if exposed to the welding-heat of iron; about 160° if exposed to the greatest heat that can be produced with charred pit-coal in a well constructed common air-furnace, &c.

The same thermometrical piece which has been used before, may be used again for higher degrees of heat, but not for lower degrees.

It is now necessary to shew the correspondence between the scale of this, and the scale of Fahrenheit's mercurial thermometer.

As the mercurial thermometer cannot shew a temperature higher than 600°, and Wedgewood's thermometer cannot shew a temperature lower than red heat, which is by several degrees higher than 600°, therefore it was necessary to contrive a measure for the intermediate degrees, and which might reach some degrees below 600°, and some degrees above the temperature of a red heat. Mr. Wedgewood chose a piece of silver, the expansion of which measured in a gauge made for the purpose, similar to the gauge fig. 241, might indicate the degrees of temperature between the two thermometers; with this instrument he first found the correspondence between the degrees of Fahrenheit's scale and the last-mentioned gauge, by placing them alternately in water of the temperature of 50°, and in boiling water. Then he found the correspondence between the degrees of the gauge of the silver piece, and that of the earthen thermometrical pieces, by placing them both at the same time in different and higher degrees of heat; lastly, by computation from those results, he determined the correspondence between the degrees of Fahrenheit's scale and those of his own thermometrical gauge.

It was found that one degree of Wedgewood's thermometer is equal to 130° of Fahrenheit's; and that the 0 of Wedgewood's coincides with the 1077,°5 of Fahrenheit's; from which data a comparison of the two thermometers may be made, or rather of the imaginary extensions of their two scales; for, in fact, Fahrenheit's thermometer cannot shew higher than 600°, and Wedgewood's cannot reach near so low. It is likewise to be observed that the degrees of Wedgewood's scale are supposed to shew equal increments of heat, whereas in truth we do not know whether the clay thermometrical pieces contract in proportion to the increments of heat; which shews that, though this is the best known thermometer for measuring the higher degrees of heat, yet an improvement of the same, or some other manageable and more accurate contrivance, is highly desirable.

Upon the whole it appears, that the spirit thermometer enables us to measure the degrees of heat as low as has ever been experienced, either naturally, or by artificial cooling: that the mercurial thermometer enables us to measure the heat from — 40° to 600°; and that Wedgewood's thermometer enables us to measure from a red heat up to the farther extent of that scale, viz. to its 240th degree, which is reckoned equivalent to 32277° of Fahrenheit's scale.

THESIUM, Base fluellin, a genus of plants of the class pentandria, and order monogynia. The calyx is monophyllous, with the stamina inserted into it; there is only one seed, which is inferior. There are nineteen species; one of which is a British plant, the linophyllum or bastard toad-flax. It has a foliaceous panicle with linear leaves, and flowers in June and July.

THLASPI, bastard-cress, or mithridate mustard, a genus of plants of the class tetradynamia, and order siliculosa; and in the natural system ranging under the 39th order, siliquosa. The pod is emarginated, obcordate, and polyspermous; the valves are boat-shaped, and marginated and carinated. There are 14 species; of which six only are natives of Britain. 1. The arvense, treacle-mustard, or penny-cress. It smells like garlic, and has a white flower. 2. The hirtum, or perennial mithridate mustard. 3. The campestre, or mithridate mustard. 4. The montanum, or mountain mithridate mustard. 5. The perfoliatum, or perfoliate treacle-mustard. 6. The bursa pastoris, or shepherd's purse. The seeds of some of these species have an acrid biting taste, approaching to that of the common mustard; with which they agree nearly in their pharmaceutic properties.

THIRD, in music, an interval so called because it contains three diatonic sounds. The Greeks not admitting the third as a consonance, it obtained no general name amongst them; but took that of the lesser or greater interval from which it was formed.

There are four species of thirds; two consonant, and two dissonant. The consonants are; first, the major third, called by the antients ditone, composed of two tones; secondly, the minor third, called hemitone, consisting of a tone and a half. The dissonant thirds are, first, the diminished third, composed of two major semitones; secondly, the superfluous third, composed of two tones and a half. This last interval, not having place in the same mode, or key, is never used either in harmony, or in melody. The Italians sometimes introduce the diminished third in airs, but it is never used in harmony.

The consonant thirds are the spirit of harmony, particularly the major third, which is sonorous and brilliant; the minor third is more tender, and even pathetic; a difference of character from which skilful composers derive some of the best and most poignant effects.

The old French theorists had almost as severe laws respecting the thirds as we now observe in regard to fifths and eighths. It was by them forbidden to have two in immediate succession even of different kinds, particularly in the same direction.

THIRTEENTH, *in music*, an interval forming the octave of the sixth, or the sixth of the octave. It contains twelve diatonic degrees, *i. e.* thirteen sounds.

THOA, a genus of the monoecia polyandria class and order of plants. There is no calyx or corolla; the male stamina are numerous; fem. germ. two; stigma three or four-cleft; seed in a brittle shell, covered with a bristly nect. There is one species.

THORACIC, a term applied to an order of fishes in the Linnean system; the character of this order of fishes is, that they have bony gills, and ventral fins placed directly under the thorax. Of this order there are 21 genera, viz. the

Cepola,	Pleuronectes,	Trachychthys,
Echineis,	Chætodon,	Gasterosteus,
Coryphæna,	Sparus,	Scomber,
Gobius,	Scarus,	Centrogaster,
Cottus,	Labrus,	Mullus,
Scorpæna,	Sciæna,	Trigla
Zeus,	Perca,	Lonchiurus.

THORACIC DUCT. See ANATOMY.

THORAX. See ANATOMY.

The thorax of insects is the back part of the breast. See ENTOMOLOGY.

THORNBACK. See RAIA.

THOUINIA, a genus of plants of the class diandria, and order monogynia. The corolla is quadripetalous, the calyx quadripartite, and the antheræ sessile. There is only one species, a tree of Madagascar.

THRASHING, or THRESHING, in agriculture, the art of beating the corn out of the ears.

THRASHING-MACHINES. The thrashing of corn by means of machinery, has been long in use in the northern districts of the kingdom, and mills of this sort are now becoming general in most parts of the country; and upon arable farms of considerable extent they cannot but be highly advantageous, as they save much labour and expence. In the making of those machines, attention should always be had to the size of the farms, or or rather the quantity of grain that may be grown on them, and the mill proportioned accordingly. They are mostly constructed on the principles of the flax-mill, and are moved either by water or horses, the first by far the best method where it can be had; the grain by these machines being, in a manner, swingled out of the ears by means of beaters which are attached to a cylinder that moves with very great velocity. Since the introduction of these machines, many improvements have been made on them; a screen has been added for the grain to pass through into a winnowing-machine, and a circular rake to remove the straw from it; as before this addition the straw was forced out from the beater upon the upper barn-floor, and required much time and labour in shaking and putting into order, which by this contrivance is saved. In working these mills, four persons are commonly necessary; one takes the sheaf from the stack, another places it ready for the third who is to feed the mill, and the fourth removes the straw to prevent its collecting in too large a quantity. It has been objected to these machines, that they do not thrash some sorts of grain clean; this has been particularly the case with barley. It is, however, observed by an intelligent writer, that the circumstance on which the good thrashing of this kind of grain depends, is the iron covering under which the beating-wheel, having six beaters, moves: in some machines this is fixed, while the beating-wheel is capable of being raised or depressed at pleasure; but a recent improvement is, to render the iron roof moveable, and the wheel fixed; and the iron is placed so near to the beaters that the grain is rubbed, as well as stricken out of the ear. In some machines of this sort, the heaters are a little rounded; but it is probably a better practice to have them of the common flat form.

In some large mills of this kind the rollers take in about three hundred inches of grain in a minute. The medium length of the straw being estimated at about thirty inches, and supposing half a sheaf to be introduced into the machine at a time, the whole sheaf will be equal to sixty inches, and the machine, when supplied with a middling quantity of water, will thrash five sheaves in a minute. But in respect to the performance of these mills much must depend on the attention with which they are fed, as a small neglect in this point will make a very considerable difference in the quantity of work done.

An excellent description of a mill of this nature is given in a late publication, in which it is remarked, that in such mills five people are commonly necessary to keep the work going on without embarrassment; but that this depends greatly on the construction of the machines, some of them being so contrived, that the work can be performed with much fewer hands. The manner in which these people are employed is this: One finds constant work in carrying the sheaves to the man who feeds or puts the unthrashed corn into the machine, and in loosing the bands; another is required to feed the machine; a third to carry off the straw; the fourth to attend the fanners, and lay aside the cleaned grain; and a fifth, where horses are made use of, to take care that they go regularly; and thus by means of five men and four horses they will thrash at the rate of five quarters in the hour on a medium, and when the crop is rich, and easily thrashed, considerably more: consequently if a thrashing-mill was to be employed for a whole day, or nine hours, it would thrash forty-five quarters; but in that case it would be necessary to employ two sets of horses. The expence is calculated in this manner:

	£.	s.	d.
Hire of eight horses, at 2*s.* 6*d.* each per day, -	1	0	0
Five men's wages, at 1*s.* 6*d.* each,	0	7	6
	£1	7	6

In this account the hire of the men and horses is, it is conceived, charged at the lowest rate, and that the expence of thrashing forty-five quarters of grain would cost about 1*l.* 7*s.* 6*d.* or about 7*d.* each quarter. But that taking the average expence of thrashing forty-five quarters of grain with the flail, throughout the whole kingdom, including an equal proportion of all kinds, it cannot be, it is supposed, estimated at less than 3*l.* 7*s.* 6*d.* or 1*s.* 6*d.* each quarter, which makes a difference of about 11*d.* each quarter. It is also farther observed, that since the introduction of these mills, the grain is thrashed by the ordinary servants on the farm, and without in any material degree obstructing the operations in the field; farmers in general employing their men and horses in this business in bad weather, when other operations cannot be carried on.

The whole expence of constructing a thrashing-mill, including the building of the shed for covering the great wheel, does not, in almost any case, exceed 100*l.* The ordinary annual repairs may, one year with another, amount to 5*l.*, which added to the interest of the prime cost, makes the yearly expence 10*l.*; a sum for which any quantity of grain, however great, that may be supposed to grow on one farm, can be thrashed, and that too in a manner much superior to what can be done by manual labour. The expence either of erecting these machines, or of keeping them afterwards in repair, must be considered by every intelligent occupier of a corn-farm as a secondary object, when compared with the advantages that are derived from them; such as the performing of the operation at less than half the ordinary price, and affording the farmer the means of securing his grain from being embezzled; besides, the saving, in regard to superior clean thrashing, as has been now well ascertained, is not only more than the annual expence of repairs, but so great as, on a farm of considerable extent, to reimburse the farmer for the whole of his expenditure in the course of a few years. Considering, therefore the increasing scarcity of labourers, and the recent great advance in the rate of labour in all the better cultivated parts of the kingdom, the introduction of thrashing-mills into common use cannot but be highly beneficial.

There is, however, one difficulty in the introduction of thrashing-mills into the southern parts of the kingdom, which arises from the manner of harvesting all kinds of grain, except wheat, which cannot probably be easily removed; as the corn, in order to be clean thrashed, should be put into the machine as straight and regular as possible. For while the sheaves, after being loosened and spread on the board, so as to be easily taken in by the feeding rollers, are passing between them, they keep the straw steady, by which means the strokes of the beaters or scutchers operate with more force and effect in separating the grain from the ears; whereas, if the unthrashed corn goes in sideways or irregularly, the thrashers can have but little power upon it. This would no doubt frequently happen in thrashing corn which has been mowed with the scythe, and which is harvested in every respect like hay; so that unless the unthrashed grain is put into the mill in small quantities, it is almost impossible that it can be completely separated from the straw.

But though, when the size of the machine is considerable, the expence of erecting it may be from eighty to one hundred pounds, according to situation and materials, smaller ones may be erected at much less, as from thirty to fifty pounds.

Some of this kind of mills have rollers or small mill-stones added to them, for the purpose of crushing and grinding grain for horses, swine, and other animals; and also instruments for cutting straw into chaff.

On the necessity of employing machines of this kind, it is remarked by an able writer, that it is the only method left for having the corn cleanly and properly thrashed. They are so quick in the work, that the whole may be done under the eye of the master, and the corn secured in the granary without the least pilfering. The saving, by this means of thrashing, in the extra quantity of corn procured, and the security against having the corn stolen in the chaff, it is asserted, amounts to an advantage in favour of the mills of about ten per cent on the corn-crops; in some cases, to one shilling a bushel on wheat, and very generally to twenty shillings an acre on the wheat-crops.

This machine has undoubtedly many advantages over the flail, as well as those of saving time and hands; as in thrashing damp corn, not capable of being fully accomplished in any other way, especially in wet seasons; and with smutty wheat, which is thrashed by it without any mischief being done to the sound grain, the smut not being crushed comes out whole, and is blown away with the chaff.

The principal objections that have been made to these machines, are the great expence of erecting and using them, their tendency to diminish the labour of the poor, and their affording too great a supply of straw at a time. These objections are, however, of little consequence, when the general utility and advantages of such machines are considered; besides the latter are either such as have nothing to be apprehended from them, or as may be readily obviated. The difficulty in regard to the straw may be easily removed, by having it properly stacked up or cut into chaff.

THRAVE, or THREAVE *of corn*, twenty-four sheaves, or four shocks of six sheaves to the shock, though, in some counties, they only reckon twelve shocks to the thrave.

THREAD, a small line made up of a number of fine fibres of any vegetable or animal substance, such as flax, cotton, or silk; from which it takes its name of linen, cotton, or silk thread.

Linen and cotton thread may be dyed of a durable and deep black by a solution of iron in sour beer, in which the linen is to be steeped for some time, and afterwards boiled in madder. See the article DYEING. Thread may be easily bleached by the oxymuriatic acid discovered by Mr. Scheele. This acid whitens cloth remarkably well, but it is still more advantageous for bleaching thread.

THREATENING LETTER. If any person shall send any letter threatening to accuse any other person of a crime punishable with death, transportation, pillory, or other infamous punishment, with a view to extort money from him, he shall be punished at the discretion of the court, with fine, imprisonment, pillory, whipping, or transportation. 80 G. II. c. 24. But if the writer of a threatening letter delivers it himself, and does not send it, he is guilty of felony under this act. Leach's Cro. Law, 351.

THRINAX, *small Jamaica fan-palm*; a genus of plants of the natural class of palmæ and order of flabellifoliæ. The calyx is sexdentate; there is no corolla; there are six stamina; the stigmas are emarginate, and the berry monospermous. This plant was brought from Jamaica to Kew gardens by Dr. William Wright.

THRIPS, a genus of the order hemiptera: the generic character is, snout inconspicuous; antennæ the length of thorax; body linear, abdomen reflexile upwards; wings four, straight, long, narrow, incumbent on the back, slightly crossed. This is a genus consisting of very small insects, which are principally found on flowers. The antennæ are submoniliform, and of the length of the thorax; the snout is obscure or inconspicuous, short, and placed beneath the neck or head; the body of a lengthened or sublinear shape, and the abdomen is at pleasure bent upwards or backwards; the wings are four in number, long, narrow, incumbent, and very slightly, or scarcely, crossed over each other.

The most familiar example of the genus is the thrips physapus of Linnæus, which is a very small slender insect, of a black colour, very frequently seen during the spring and summer on various flowers, more especially on what are termed the compound flowers, as dandelion, &c. It wanders about the petals of the flower, descending to the bottom of the florets, occasionally emerging at intervals, and often skipping from place to place, in performing which action it is observed suddenly to turn back its abdomen, so as nearly to touch the thorax with its tip. The wings are of a semitransparent white, narrow, and when properly magnified, are observed to be edged and tipped with hairs growing gradually longer as they approach the tips, where they are of considerable length: the lower wings are rather shorter than the upper, beneath which they are, in general, almost concealed; the antennæ consist of six joints, and the feet are tipped with an expansile and apparently vesicular process, enabling the little animal to adhere at pleasure with the greater security to any particular substance. All these particulars require a microscope for their investigation, the whole insect not exceeding the tenth of an inch in length. The larva in a great degree resembles the complete insect, but is destitute of wings; when very young it is white, and afterwards of a yellowish or reddish colour, and like the complete insect, is seen wandering about the petals of flowers.

The thrips physapus has been supposed to do much injury to wheat, rye, &c. by causing the young flowers to decay, thus preventing the growth of the embryo grain. This opinion, however, has by some been considered as erroneous; who have contended that the thrips does not attach itself to such of the cerealia as are in a perfect healthy state, but rather to such as are diseased by having the germina covered with the dust of a very minute fungus, often growing on wheat, &c. and belonging to the genus æcidium or lycoperdon, and which makes its appearance in the form of a flattish, smooth, irregular exsudation, of a yellow colour, on various parts of the plant. See TRITICUM. The ingenious Mr. Kirby, however, seems convinced that the thrips is in reality an insect highly injurious to corn, by deriving its nourishment from the embryo grains. There are eight species.

THRUSH. See TURDUS.

THRYALLIS, a genus of plants of the class decandria, and order monogynia; and in the natural system ranging under the 38th order, tricoccæ. The calyx is quinquepartite, there are five petals, and the capsule is tricoccous. There is only one species known, the brasiliensis, a shrub of Brasil.

THUJA, the *arbor vitæ*, a genus of plants of the class monadelphia, and order monœcia; and in the natural system ranging under the 51st order, coniferæ. There are four species known; the orientalis, occidentalis, articulata, and dolabrata; of which the two first are most remarkable. 1. The occidentalis or common arbor vitæ, grows naturally in Canada, Siberia, and other northern countries. In some of the English gardens a few of these trees are to be met with of a large size; it has a strong woody trunk, which rises to the height of 40 feet or more. The bark, while young, is smooth, and of a dark-brown colour; but as the trees advance, the bark becomes cracked, and less smooth. The branches are produced irregularly on every side, standing almost horizontal, and the young slender shoots frequently hang downward, thinly garnished with leaves; so that when the trees are grown large, they make but an indifferent appearance. The leaves of this tree have a rank oily scent when bruised. 2. The orientalis, or China arbor vitæ, grows naturally in the northern parts of China, where it rises to a considerable height; but this has not been long enough in Europe to have any trees of large size. The seeds of this sort were first sent to Paris by some of the missionaries; and there are several of the trees growing in the gardens of the curious there, which are more than twenty feet high. The branches of this sort grow closer together, and are much better adorned with leaves, which are of a brighter-green colour, so as to make a better appearance than the other; and being very hardy, it is esteemed preferable to most of the evergreen trees with small leaves, for ornament in gardens. These trees are propagated by seeds, layers, or cuttings.

THUMMERSTONE. This stone was first described by Mr. Schreber, who found it near Balme D'auris in Dauphiné, and gave it the name of shorl violé. It was afterwards found near Thum in Saxony, in consequence of which Werner called it thummerstone. It is sometimes amorphous, but more commonly crystallized. The primitive form of its crystals is a rectangular prism, whose bases are parallelograms with angles of 101° 32 and 78° 28. The most usual variety is a flat rhomboidal parallelopiped, with two of its opposite edges wanting, and a small face in place of each. The faces of the parallelopiped are generally streaked longitudinally.

The texture of thummerstone is foliated. Its fracture conchoidal. Glassy. Causes simple refraction. Specific gravity 3.2956. Colour clove-brown; sometimes inclining to red, green, grey, violet, or black. Before the blowpipe it froths like zeolite, and melts into a hard black enamel. With borax it exhibits the same phenomena, or even when the stone is simply heated at the end of a pincer.

A specimen of thummerstone, analysed by Klaproth, contained

52.7 silica
25.6 alumina
9.4 lime
9.6 oxide of iron, with a trace of manganese.

97.3.

A specimen, analysed by Vauquelin, contained

44 silica
18 alumina
19 lime
14 oxide of iron
4 oxide of manganese

99.

THUNDER. See ELECTRICITY.

THUNBERGIA, a genus of plants belonging to the class and order didynamia angiospermia. The calyx is double; the corolla bell-shaped; capsules beaked. There are 2 species.

THUS. See RESINS.

THYMBRA, a genus of the class and order didynamia angiospermia. The calyx is two-lipped; seeds semibifid. There are 3 species.

THYMUS, THYME, a genus of plants of the class didynamia, and order gymnospermia; and in the natural system ranging under the 42d order, verticillatæ. The calyx is bilabiate, and its throat closed with soft hairs. There are 22 species; of which only two are natives of Britain, the serpyllum and acinas. 1. The serpyllum, or mother of thyme, has pale red flowers growing on round heads, terminal; the stalks are procumbent, and the leaves plane, obtuse, and ciliated at the base. 2. The acinas, or wild basil, has flowers growing in whorls on single footstalks; the stalks are erect and branched; the leaves acute and serrated. The thymus vulgaris, or garden thyme, is a native of France, Spain, and Italy. The attachment of bees to this and other aromatic plants is well known. In the experiments made at Upsal, sheep and goats were observed to eat it, and swine to refuse it.

THYMUS, in anatomy, a gland, which in infants is very remarkable; it is situated in the upper part of the thorax, immediately under the sternum, and lies upon the pericardium, and on the trunk of the aorta and of the vena cava. See ANATOMY.

THYNNUS, a genus of the hymenoptera order of insects. The generic character is, mouth horny, with an incurved mandible; the jaw short and straight; lip longer than the jaw, membranaceous at the tip, and trifid, the middle divison emarginate; tongue very short, involute; feelers four, equal, filiform; antennæ cylindrical, the first joint thicker. There are four species, three inhabiting New Holland, and the fourth is found in Africa.

THYROID GLAND. See ANATOMY.

THYRSUS, in botany, a mode of flowering resembling the cone of a pine.

TIARELLA, a genus of plants of the class decandria, and order digynia, and in the natural system ranging under the 13th order, succulentæ. The calyx is quinquepartite; the corolla pentapetalous, and inserted into the calyx; the petals are entire; the capsule is unilocular and bivalve, one valve being less than the other. There are two species, the cordifolia and trifoliata, natives of North America.

TIBIA. See ANATOMY.

TIBIALIS, or TIBIÆUS. See ANATOMY.

TIDES. See ASTRONOMY.

TIDE-WAITERS, or *tidesmen*, are inferior officers belonging to the custom-house, whose employment it is to watch or attend upon ships, until the customs are paid; they get this name from going on board ships on their arrival in the mouth of the Thames or other port, and so coming up with the tide.

TIERCE, or TEIRCE, a measure of liquid things, as wine, oil, &c. containing the third part of a pipe, or forty-two gallons. See MEASURE.

TIGER. See FELIS.

TIGER-SHELL, a beautiful species of voluta, of a dusky-red colour, spotted all over with large irregular blotches of white: it is brought from the East Indies, and is about two inches and a half in length, and about an inch in diameter.

TILE, in building, a sort of thin brick, used on the roofs of houses; or more properly a kind of clayey earth, kneaded and moulded of a just thickness, dried and burnt in a kiln, like a brick, and used in the covering and paving of different kinds of military and other buildings. The best brick-earth only should be made into tiles.

The tiles for all sorts of uses may now be comprised under seven heads, viz. 1. The plain tile for covering of houses, which is flat and thin. 2. The plain tile for paving, which is also flat, but thicker; and its size 9, 10, or 12 inches. 3. The pan-tile, which is also used for covering of buildings, and is hollow, and crooked, or bent, somewhat in the manner of an S. 4. The Dutch glazed pan-tile. 5. The English glazed pan-tile. 6. The gutter-tile, which is made with a kind of wings. And 7. The hip or corner-tile.

TILES, *plain*, are best when they are firmest, soundest, and strongest. Some are duskier, and others ruddier, in colour. The dusky-coloured are generally the strongest. These tiles are not laid in mortar, but pointed only in the inside.

TILES, *paving*, are made of a more sandy earth than the common or plain tiles; the materials for these last must be absolute clay, but for the others a kind of loam is used. These are made thicker and larger than the common roof-tiles; and when care has been taken in the choice of the earth, and the management of the fire, they are very regular and beautiful.

TILES, *pan*, when of the best kind, are made of an earth not much unlike that of the paving-tiles, and often of the same; but the best sort of all is a pale-coloured loam that is less sandy; they have about the same degree of fire given them in the baking, and they come out nearly of the same colour. These tiles are laid in mortar, because the roof being very flat, and many of them warped in the burning, they will not cover the building so well that no water can pass between them.

TILES, *pan, Dutch glazed*, get the addition of glazing in the fire. Many kinds of earthy matter running into a glassy substance in great heat, is a great advantage to them; preserving them much longer than the common pan-tiles, so that they are very well worth the additional charge that attends the using them.

TILES, *pan, English glazed*, are in general not so good as the Dutch ones under that denomination, but the process is nearly the same.

TILES, *Dutch*, for chimneys, are of a kind very different from all the rest. They are made of a whitish earth, glazed and painted with various figures, such as birds, flowers, or landscapes, in blue or purple colour, and sometimes quite white; they are about 6.5 inches each way, and three quarters of an inch thick. They are seldom used at present.

TILES, *gutter*, are made of the same earth as the common pan-tiles, and only differ from them in shape; but it is advisable that particular care is taken in tempering and working the earth for these, for none are more liable to accidents. The edges of these tiles are turned up at the larger ends for about four inches. They are seldom used where lead is to be had.

TILES, *hip* or *corner*, are at first made flat, like pan-tiles of a quadrangular figure, whose two sides are right lines, and the ends arches of circles; the upper end concave, and the lower convex the latter being about seven times as broad as the other; they are about 10.5 inches long; but before they are burnt, are bent upon a mould in the form of a ridge tile, having a hole at the narrow end, to nail them on the hip-corner of the roof.

TILES, *ridge*, are used to cover the ridges of houses, and are made in the form of a semi-cylindrical surface, about 13 inches in length, and of the same thickness as plain tiles; their breadth at the outside measures about sixteen inches.

TILIA, *lime*, or *linden-tree*, a genus of plants of the class polyandria, and order monogynia, and in the natural system ranging under the columniferæ. The calyx is quinquepartite; the corolla pentapetalous; the caps. is dry, globose, quinquelocular, quinquevalve, and opening at the base. There are four species; the europæa, americana, pubescens, and alba. The europæa, or common lime-tree, is generally supposed to be a native of Britain; but we are informed by Mr. Coxe, that Mr. Pennant told him (on what authority is not mentioned) that it was imported into England before the year 1652. The wood is light, smooth, and of a spongy texture, used for making lasts and tables for shoemakers, &c. Ropes and bandages are made of the bark, and mats and rustic garments of the inner rind, in Carniola and some other countries. The lime-tree contains a gummy juice, which being repeatedly boiled and clarified, produces a substance like sugar.

TILLANDSIA, a genus of the hexandria monogynia class of plants, with a tubulated monopetalous flower, trifid at the limb; the fruit is a long, obtusely trigonal, and acuminated capsule, formed of three valves, and containing only one cell, with numerous seeds affixed to a long capillary plume. There are 16 species.

TILLER *of a ship*, a strong piece of wood fastened in the head of the rudder, and in small ships and boats called the helm.

In ships of war, and other large vessels, the tiller is fastened to the rudder in the gun-room; and to the other end there are ropes fastened, which pass upwards to the quarter-deck, where the ship is steered by means of a wheel.

TILLŒA, a genus of plants of the class tetrandria, and the order tetragynia, and in the natural system ranging under the 13th order, succulentæ. The calyx has three or four divisions; the petals are three or four, and equal; the capsules three or four, and polyspermous. There are eight species, of which one only, the muscosa, is a native of England. The muscosa, or procumbent tillœa, has prostrate stems, almost erect, generally red, and growing longer after flowering. The parts of fructification are always three. The leaves grow in pairs, and are fleshy. It is found on dry heaths in Norfolk and Suffolk, and flowers in May and June.

TILLAGE. See HUSBANDRY.

TILT-BOAT, a boat covered with a tilt, that is, a cloth or tarpawlin, sustained by hoops, for the sheltering of passengers.

TIMBER, includes all kinds of felled and seasoned woods. See ACER, BETULUS, FRAXINUS, QUERCUS, PINUS, PLATANUS, POPULUS, ULMUS, &c.

Of all the different kinds known in Europe, oak is the best for building, and even when it lies exposed to air and water, there is none equal to it. Fir-timber is however perhaps more generally useful than any other. It is used for flooring, wainscoting, and the ornamental parts of building within doors. Elm is the next in use, especially in England and France; it is very tough and pliable, and therefore easily worked; it does not readily split; and it bears driving of bolts and nails better than any other wood. Ash is chiefly used by wheelwrights and coachmakers, for shafts, naves, &c. Beech is also used for many purposes; it is very tough and white when young, and of great strength, but liable to warp very much when exposed to the weather, and to be worm-eaten when used within doors; its greatest use is for planks, bedsteads, chairs, and other household goods. Wild-chesnut timber is by many esteemed to be as good as oak, and seems to have been much used in old buildings; but whether these trees are more scarce at present than formerly, or have been found not to answer so well as was imagined, this timber is now but little used. Walnut-tree is excellent for the joiner's use, it being of a more curious brown colour than beech, and not so subject to the worms. The poplar, abel, and aspen-tree, which are very little different from each other, are sometimes used instead of fir, but mostly by turners, &c. The goodness of timber not only depends on the soil and situation in which it stands, but likewise on the season wherein it is felled. In this, people disagree very much; some are for having it felled as soon as its fruit is ripe, others in the spring, and many in the autumn. But as the sap and moisture of timber are certainly the causes that it perishes much sooner than it otherwise would do, it seems evident that timber should be felled when there is the least sap in it, viz. from the time that the leaves begin to fall, till the trees begin to bud. This work usually commences about the end of April in England, because the bark then rises most freely; for where a quantity of timber is to be felled, the statute requires it to be done then, for the advantage of tanning.

After timber has been felled and sawed, it must be seasoned; for which purpose some advise it to be laid up in a very dry airy place, yet out of the wind and sun, or at least free from the extremities of either; and that it may not decay, but dry evenly, they recommend it to be daubed over with cow-dung. It must not stand upright, but lie all along, one piece over another, only kept apart by short blocks interposed, to prevent a certain mouldiness which they are otherwise apt to contract in sweating on one another; from which arises frequently a kind of fungus, especially if there are any sappy parts remaining. Others advise the planks of timber to be laid for a few days in some pool or running stream, in order to extract the sap, and afterwards to dry them in the sun or air. By this means, it is said, they will be prevented from either chopping, casting, or cleaving, but against shrinking there is no remedy. Some again are for burying them in the earth, others in a heat; and some for scorching and seasoning them in fire, especially piles, posts, &c. which are to stand in water or earth. The Venetians first found out the method of seasoning by fire, which is done after this manner: they put the piece to be seasoned into a strong and violent flame, in which they continually turn it round by means of an engine, and take it out when it is every where covered with a black coaly crust; when the internal part of the wood is so hardened, that neither earth nor water can damage it for a long time afterwards.

After the planks of timber have been well seasoned and fixed in their places, care is to be taken to defend or preserve them; to which the smearing them with linseed-oil, tar, or other oleaginous matter, contributes much.

To measure round timber, let the mean circumference be found in feet and decimals of a foot; square it, multiply this square by the decimal 0.079577, and the product by the length. Ex. Let the mean circumference of a tree be 10.3 feet, and the length 24 feet. Then $10.3 \times 10.3 \times 0.079577 \times 24 = 202.615$, the number of cubical feet in the tree. The foundation of this rule is, that when the circumference of a circle is 1, the area is 0.0795774715, and that the areas of circles are as the squares of their circumferences.

But the common way used by artificers for measuring round timber, differs much from this rule. They call one-fourth part of the circumference the girt, which is by them reckoned the side of a square whose area is equal to the area of the section of the tree; they therefore square the girt, and then multiply by the length of the tree. According to their method, the tree of the last example would be computed at 159.13 cubical feet only.

For measuring hewn or square timber, the custom is to find the middle of the length of the tree, and there to measure its breadth, by clapping two rules to the sides of the tree, and measuring the distance betwixt them; in like manner they measure the breadth the other way. If the two are found unequal, they are added together, and half their sum is taken for the true side of the square.

TIMBER, *strength of.* "After spending much time," says Mr. Smart, "in making various experiments, and comparing the results with those of Buffon, Belidore, &c. the differences were so great, that it would be wasting time to enumerate them: I shall therefore only mention some useful observations necessary to be known by all those mechanics who use timber; and point out some evident errors in a table of Belidore's, supposed to be the result of the best set of experiments ever produced in transverse strains. He tells us, that a bar of wood, thirty-six inches long, and one inch square, supported at the ends by two props, will break with a weight of 187 pounds on the middle, if it is loose at the ends; but if the ends are firmly fixed, it will require 283 pounds to break it. "This appeared to me so great an error, that I was induced to put little or no confidence in many of his experiments; and, in consequence, I made two laths of fir, of the same dimensions, one with a strong shoulder at each end, to prevent its bending, which having firmly fixed in a frame, it carried a weight more than ten times greater than that which was loose."

The fibres of timber requiring so great a force to tear them asunder in a vertical direction, and being easily broken by a transverse strain, when compared to that of a rope carrying nearly an equal weight in all directions, opens a wide field for useful experiments. All timber-trees have their annual circles, or growths, which vary greatly according to the soil and exposure to the sun. The north-east side of the trees (being much smaller in the grain than the other parts, which are more exposed to the sun) is strongest for any column that has a weight to support in a vertical direction; because its hard circles, or tubes, are nearer each other, and the area contains a greater quantity of them; nor are they so liable to be compressed by the weight, or to slide past each other, as when they are at a greater distance. On the other hand, this part of the tree is not fit for a transverse strain; because the nearer the hard circles are to each other, the easier the beam will break, there being so little space between them, that one forms a fulcrum to break the other upon: but that part of a tree, the tubes of which are at a greater distance, or of larger grain, is more elastic, and requires a greater force to break it; because the outside fibre on the convex side; cannot snap till the next one is pressed upon it, which forms the fulcrum to break it on. It is generally observed in large timbers, such as masts, that the fracture is seldom on the convex, but usually on the concave side; which is owing to the fibres on the concave side being more readily forced past each other, and those on the convex being so difficult to be torn asunder, that they cannot snap, in consequence of the largeness of the segment of the circle they describe when on the strain. The curve described by the inner layers of the wood being so large, and indeed little less than a straight line, cannot form a fulcrum to break the outer ones upon; and as the convex side, or that on which the fibres are extended, ought to be always free from any mortise or incision on the outside, the strength decreases as it approaches the centre.

Figs. 6, 7, 8, 9, and 10, Plate Ship-building, describe the simple method invented by Mr. George Smart, of converting all timber that is straight, and intended for square beams, to great advantage in general use. Fig. 8 is a section of the but-end of a tree, two feet in diameter, sawn or chopped diagonally. Fig. 9 is the other end, sawn square, one foot each side: cut it exactly through the centre in two cross-cuts *ab*, *de*, it will produce four pieces; which are put together, as in figs. 6 and 7, with the centre turned outwards, the but-end of one piece with the small end of the other, and dowel or bolt them together as fig 10: you will then form a beam, whose section is shewn in figs. 6 and 7, regular from one end to the other, with the advantage of having the heart of the tree in the place where the hardness and strength are most wanted, viz. in the corners which form the abutments; whereas, the same tree squared into a parallel beam, would have been much smaller, and the soft or sappy parts of the wood exposed to the action of the air and moisture. In flush-framing it is observable, that the failure of all timber in old buildings has commenced much sooner than they otherwise would have done, owing to the sappy wood being at the corners of the principal beams, which soon decays, as its spongy quality attracts the moisture; whereas the heart, especially of oak, will be as sound as the first day it was used.

As all beams take their weight horizontally, or on any transverse bearing, have their principal strain on the upper and lower surface, every workman ought to guard against having sap in beams, because if they do not immediately decay, they shrink, so as to let loose all the framing, and soon cripple the building or machine: but on Mr. Smart's plan the sappy part of the wood is excluded from what would cause its decay, and the timber increased in quantity is considerably more than the extra labour and expence.

A tree of oak, forty feet long and two feet diameter at the but-end, and one foot at the top, when put together on this plan, will have its sides each 18 inches square, which contains 90 feet; whereas, on the old plan 40 would be the content of a square beam, cut from the same tree; 50 cubic feet would have been cut off as slabs, or chopped up for the fire. The expence of sawing and putting a beam of the above dimensions in London in the year 1802 would have been as follows:

	l.	*s.*	*d.*
Four outside cuts at 14 inches deep; Two breaking, cut at 18; Length 40 feet, 306 feet sawing at 7*s.* 6*d.*	1	3	0
120 12-inch dowels, at 1*d.* each	0	10	0
Boring 240 holes, and putting together - -	1	5	0
	2	18	0

Allowing the 50 feet saved to be worth 6*l.* then the proprietor would save 3*l.* 2*s.* in each beam so converted. The dowels ought not to go through, as that would weaken the timber. In an 18-inch beam the dowels should come within three inches of the outside; but where a mortise is cut in place of a dowel, it is proper to have an iron screw bolt to prevent the joint opening with the pressure of the tennon; and the work ought to be put together with screw clamps, for nails or hammers bruise the wood, and destroy he cohesion of its fibres for a considerable depth. The method we are here describing is included in Mr. Smart's patent for hollow masts described in our article SHIP; yet, as far as relates to lessening the consumption of English oak, and introducing the larch and firs of our own growth into general use, Mr. Smart has liberally granted licences to all who chose to apply to him for them, masts, yards, bowsprits, &c. excepted.

TIMBER TREES, in law, are properly oak, ash, and elm. In some particular countries, by local custom, other trees being commonly there made use of for building, are considered as timber. 2 Black. 28. Of these, being part of the freehold, larceny cannot be committed; but if they are severed at one time, and carried away at another, then the stealing of them is larceny. And by several late statues the stealing of them in the first instance is made felony, or incurs a pecuniary forfeiture. 4 Black. 233.

For the better preservation of roots, shrubs, and plants, it is by the 6 G. III. c. 48, enacted, that from and after the 24th day of June, 1766, every person convicted of damaging, destroying, or carrying away any timber tree or trees, or trees likely to become timber, without consent of the owner, &c. shall forfeit for the first offence not exceeding 20*l.* with the charges attending; and on non-payment shall be committed for not more than twelve, nor less than six, months; for the second offence, a sum not exceeding 30*l.* and on non-payment shall be committed for not more than eighteen, and not less than twelve, months; and for the third offence is to be transported for seven years. All oak, beech, chesnut, walnut, ash, elm, cedar, fir, asp, lime, sycamore, and birch, trees, shall be deemed and taken to be timber-trees within the intent of this act.

By the same act, the plucking or spoiling of roots, shrubs, or plants, is subject to a fine of 4*l.* for the first offence, and 5*l.* for the second, and transportation for the third. Justices of peace are to put this act in execution.

TIME, in music, is an affection of sound, by which we denominate it long or short, with regard to its continuauce.

Common, or double time, is of two species. 1. When every bar or measure is equal to a semibreve, or its value in any combination of notes of a lesser quantity. 2. When every bar is equal to a minim, or its value in lesser notes. The movements of this kind of measure are various, but there are three common distinctions; the first slow, signified by the mark C; the second brisk, signified by ₵; the third very quick, signified by ₵.

The old musicians were acquainted with no more than two sorts of time: one of three measures in a bar, which they called perfect; and the other of two, considered as imperfect. When the time was perfect, the breve was equal to three semibreves, which was expressed by an entire circle, barred or not barred, and sometimes also by this compound character $\frac{3}{1}$. When the time was imperfect, the breve was equal only to two semibreves, which was indicated by a semicircle, or C. Sometimes the C was reversed, as thus Ɔ, which signified a diminution, by one-half, of the powers of the notes; a particularity sometimes denoted in the more modern music by a perpendicular bar drawn through the character, as thus ₵. The time of the full C was generally called the major time, and that of the reversed Ɔ the minor time.

The moderns have added to the old music a combination of times; but still we may say that we have no more than two times, common and triple: since the time of nine crotchets, or nine quavers in a bar, is but a species of triple time; and that of six crotchets, or six quavers in a bar, though called a compound common time, being measured by two beats, one down and one up, is as absolutely common time as that of four crotchets in a bar.

With respect to the velocities of the different species of time, they are as various as the measures and modifications of music, and are generally expressed by some Italian word or phrase at the beginning of each movement, as larghetto (rather slow), presto (quick), &c. But when once the time of the improvement is determined, all the measures are to be perfectly equal, that is, every bar is to take up the same quantity of time, and the corresponding divisions of the bars are to be perfectly symmetrical with respect to each other.

TIME-KEEPERS, in a general sense, denote instruments adapted for measuring time. See CHRONOMETER.

In a more peculiar and definite sense, time-keeper is a term first applied by Mr. John Harrison to his watches constructed for determining the longitude at sea, and for whcih he received, at different times, the parliamentary reward of twenty thousand pounds. Several other artists have since received also considerable sums for their improvements of time-keepers, as Arnold, Mudge, &c. See LONGITUDE.

This appellation is now become common among artists, to distinguish such watches as are made with extraordinary care and accuracy for nautical or astronomical observations.

The principles of Mr. Harrison's time-keeper, as they were communicated by himself to the commissioners appointed to receive and publish the same in the year 1765, are as follow:

"In this time-keeper there is the greatest care taken to avoid friction, as much as can be, by the wheels moving on small pivots, and in ruby-holes, and high numbers in the wheels and pinions.

"The part which measures time goes but the eighth part of a minute without winding up; so that part is very simple, as this winding-up is performed at the wheel next to the balance-wheel, by which means there is always an equal force acting at that wheel, and all the rest of the work has no more to do in the measuring of time than the person that winds up once a day.

"There is a spring in the inside of the fusee, which I will call a secondary main spring. This spring is always kept stretched to a certain tension by the main spring; and during the time of winding up the time-keeper, at which time the main spring is not suffered to act, this secondary spring supplies its place.

"In common watches in general, the wheels have about one-third the dominion over the balance that the balance-spring has; that is, if the power which the balance-spring has over the balance is called three, that from ie wheel is one; but in this time-keeper the heels have only about one-eightieth part of ie power over the balance that the balance-pring has; and it must be allowed, the less ie wheels have to do with the balance, the etter. The wheels in a common watch aving this great dominion over the balance, iey can, when the watch is wound up, and ie balance at rest, set the watch a going; ut when my time-keeper's balance is at rest, nd the spring is wound up, the force of the heels can no more set it a going than the heels of a common regulator can, when the eight is wound up, set the pendulum a ibrating; nor will the force from the wheels iove the balance when at rest, to a greater ngle in proportion to the vibration that it is fetch, than the force of the wheels of a ommon regulator can move the pendulum om the perpendicular, when it is at rest.

"My time-keeper's balance is more than iree times the weight of a large-sized comion watch balance, and three times its diaieter; and a common watch balance goes irough about six inches of space in a second, ut mine goes through about twenty-four ıches in that time; so that had my time-eeper only these advantages over a common atch, a good performance might be expected from it. But my time-keeper is not affectd by the different degrees of heat and cold, or agitation of the ship; and the force from he wheels is applied to the balance in such a ianner, together with the shape of the baınce-spring, and, if I may be allowed the erm, an artificial cycloid, which acts at this pring; so that from these contrivances, let he balance vibrate more or less, all its vibraions are performed in the same time; and herefore if it goes at all, it must go true. So hat it is plain from this, that such a timeeeper goes entirely from principle, and not om chance."

We must refer those who may desire to see minute account of the construction of Mr. Iarrison's time-keeper, to the publication y order of the commissioners of longitude.

We shall here subjoin a short view of the nprovements in Mr. Harrison's watch, from he account presented to the board of longiude by Mr. Ludlam, one of the gentlemen o whom, by order of the commissioners, Mr. Iarrison discovered and explained the prineiple upon which his time-keeper is contructed. The defects in common watches which Mr. Harrison proposes to remedy, are hiefly these: 1. That the main spring acts ıot constantly with the same force upon the wheels, and through them upon the balance. 2. That the balance, either urged with an ınequal force, or meeting with a different reistance from the air, or the oil, or the fricion, vibrates through a greater or less arch. 3. That these unequal vibrations are not performed in equal times. And, 4. That the orce of the balance-spring is altered by a change of heat.

To remedy the first defect, Mr. Harrison ıas contrived that his watch shall be moved by a very tender spring, which never unrolls tself more than one-eighth part of a turn, and acts upon the balance through one wheel only. But such a spring cannot keep the watch in motion a long time. He has, therefore, joined another, whose office is to wind ip the first spring eight times in every minute, and which is itself wound up but once a day. To remedy the second defect, he uses a much stronger balance-spring than in a common watch. For if the force of this spring upon the balance remains the same, whilst the force of the other varies, the errors arising from that variation will be the less, as the fixed force is the greater. But a stronger spring will require either a heavier or a larger balance. A heavier balance would have a greater friction. Mr. Harrison, therefore, increases the diameter of it. In a common watch it is under an inch, but in Mr. Harrison's, two inches and two tenths. However, the methods already described only lessening the errors, and not removing them, Mr. Harrison uses two ways to make the times of the vibrations equal, though the arches may be unequal: one is to place a pin so that the balance-spring pressing against it, has its force increased, but increased less when the vibrations are larger; the other, to give the pallets such a shape, that the wheel may press them with less advantage when the vibrations are larger. To remedy the last defect, Mr. Harrison uses a bar compounded of two thin plates of brass and steel, about two inches in length, riveted in several places together, fastened at one end, and having two pins at the other, between which the balance-spring passes. If this bar is straight in temperate weather (brass changing its length by heat more than steel), the brass side becomes convex when it is heated, and the steel side when it is cold; and thus the pins lay hold of a different part of the spring in different degrees of heat, and lengthen or shorten it as the regulator does in a common watch.

The principles on which Mr. Arnold's time-keeper is constructed are these: The balance is unconnected with the wheel-work, except at the time it receives the impulse to make it continue its motion, which is only whilst it vibrates 10° out of 380°, which is the whole vibration; and during this small interval it has little or no friction, but what is on the pivots, which work in ruby holes on diamonds. It has but one pallet, which is a plane surface formed out of a ruby, and has no oil on it. Watches of this construction, says Mr. Lyons, go whilst they are wound up; they keep the same rate of going in every position, and are not affected by the different forces of the spring; and the compensation for heat and cold is absolutely adjustable.

TIN, a metal known to the antients: the Phenicians procured it from Spain and Britain, with which nations they carried on a very extensive and lucrative commerce. This metal has a fine white colour, like silver; a slight disagreeable taste, and emits a peculiar smell when rubbed. Its specific gravity is 729. It is very malleable. Tin-leaf or foil is about $\frac{1}{1000}$th part of an inch thick, and it might be reduced to half this thickness. It is very flexible, and produces a remarkable crackling noise when bended, and when heated to 442° it melts. When exposed to the air it very soon loses its lustre, and assumes a greyish-white colour, but undergoes no farther change. Neither is it sensibly altered by being kept under cold water; but when the stream of water is made to pass over redhot tin, it is decomposed, the tin is oxidated, and hydrogen gas is evolved.

When tin is melted in an open vessel, its surface becomes very soon covered with a grey powder, which is an oxide of the metal. If the heat is continued, the colour of the powder gradually changes, and at least it becomes yellow. In this state it is known by the name of putty, and employed in polishing glass and other hard bodies. When tin is heated very violently in an open vessel, it takes fire, and is converted into a fine white oxide, which may be obtained in crystals.

Tin is capable of combining with two different proportions of oxygen, and of forming two oxides; usually distinguished, on account of their colour, by the names of the yellow and the white oxide.

The protoxide may be obtained by exposing tin to a strong heat under a muffle, constantly stirring it with a rod. It may be procured also by dissolving tin in diluted nitric acid without the assistance of heat, and then precipitating the oxide by pure potass; but in that case it retains a little acid, and has a white colour. It is composed of about 20 parts of oxygen and 80 of tin.

The peroxide may be obtained by heating tin in concentrated nitric acid. A violent effervescence ensues, and the whole of the tin is converted into a white powder, which is deposited at the bottom of the vessel. It is composed of about 28 parts of oxygen and 72 of tin.

Tin combines with sulphur and phosphorus; but it has never been combined with carbon or hydrogen.

Sulphuret of tin may be formed by throwing bits of sulphur upon the metal melted in a crucible, or by fusing the two ingredients together. It is brittle, heavier than tin, and not so fusible. It is of a blueish colour and lamellated structure, and is capable of crystallizing. According to Bergman, it is composed of 80 parts of tin and 20 of sulphur; according to Pelletier, of 85 parts of tin and 15 of sulphur.

When equal parts of white oxide of tin and sulphur are mixed together and heated gradually in a retort, some sulphur and sulphurous acid are disengaged; and there remains a substance composed of 40 parts of sulphur and 60 of white oxide of tin, formerly called aurum musivum, musicum, or mosaicum, and now sulphureted oxide of tin. It consists of beautiful gold-coloured flakes, exceedingly light, which adhere to the skin. The process for making this substance was formerly very complicated. Pelletier first demonstrated its real composition, and was hence enabled to make many important improvements in the manner of manufacturing it.

Phosphuret of tin may be formed by melting in a crucible equal parts of filings of tin and phosphoric glass. Tin has a greater affinity for oxygen than phosphorus has. Part of the metal therefore combines with the oxygen of the glass during the fusion, and flies off in the state of an oxide, and the rest of the tin combines with the phosphorus. The phosphuret of tin may be cut with a knife; it extends under the hammer, but separates in laminæ. When newly cut, it has the colour of silver; its filings resemble those of lead. When these filings are thrown on burning coals, the phosphorus takes fire. This phosphuret may likewise be formed by dropping phosphorus gradually into melted tin. According to Pelletier, to whose experiments we are indebted for the knowledge of all the phosphurets, it is composed of about

85 parts of tin and 15 of phosphorus. Margraf also formed this phosphuret, but he was ignorant of its composition.

Tin does not combine with azote or muriatic acid; though the last substance converts it into an oxide.

Tin is capable of combining with most of the metals, and some of its alloys are much employed. The greater number of them are brittle. The older metallurgists considered it as a property of tin to render other metals brittle. Hence they called it diabolus metallorum.

1. It mixes readily with gold by fusion; but the proportions in which these metals combine chemically are still unknown. When one part of tin and twelve of gold are melted together, the alloy is brittle, hard, and bad-coloured. Twenty-four parts of gold and one of tin produce a pale-coloured alloy, harder than gold, but possessed of considerable ductility. Gold alloyed with no more than $\frac{1}{37}$ of tin is scarcely altered in its properties, according to Mr. Alchorne; but Mr. Tillet, who more lately examined this alloy, found, that whenever it was heated it broke into a number of pieces. It is very difficult to separate these metals from each other. The method is, to fuse the alloy with sulphuret of antimony.

2. The alloy of platinum and tin is very fusible and brittle, at least when these metals are mixed in equal proportions. Twelve parts of tin and one of platinum form an alloy possessed of considerable ductility, which becomes yellow when expo ed to the air.

3. The alloy of silver and tin is very brittle, hard, and durable. The two metals can scarcely be separated again by the usual processes. This alloy has been applied to no use.

4. Mercury dissolves tin very readily cold; and these metals may be combined in any proportion by pouring mercury into melted tin. The amalgam of tin, when composed of three parts of mercury and one of tin, crystallizes in the form of cubes, according to Daubenton; but, according to Sage, in grey brilliant square plates, thin towards the edges, and attached to each other so that the cavities between them are polygonal. It is used to silver the backs of glass mirrors. See FOLIATION *of looking-glasses*.

5. Tin unites very readily with copper, and forms an alloy exceedingly useful for a great variety of purposes. Of this alloy cannons are made; bell-metal; bronze; and the mirrors of telescopes, are formed of different proportions of the same metals. The addition of tin diminishes the ductility of copper, and increases its hardness, tenacity, fusibility, and sonorousness. The specific gravity of the alloy is greater than the mean density of the two metals. It appears, from the experiments of Mr. Briche, that this augmentation of density increases with the tin; and that the specific gravity, when the alloy contains 100 parts of copper and 16 of tin, is a maximum: it is 8.87. The specific gravity of equal parts of tin and copper is 8.79, but it ought only to be 8; consequently the density is increased 0.79. In order to mix the two metals exactly, they ought to be kept a long time in fusion, and constantly stirred, otherwise the greater part of the copper will sink to the bottom, and the greater part of the tin rise to the surface; and there will be formed two different alloys; one composed of a great proportion of copper combined with a small quantity of tin, the other of a great proportion of tin alloyed with a small quantity of copper.

Bronze and the metal of cannons are composed of from 6 to 12 parts of tin combined with 100 parts of copper. This alloy is brittle, yellow, heavier than copper, and has much more tenacity; it is much more fusible, and less liable to be altered by exposure to the air. It was this alloy which the antients used for sharp-edged instruments before the method of working iron was brought to perfection. The χαλκος of the Greeks, and perhaps the *æs* of the Romans, was nothing else. Even their copper coins contain a mixture of tin.

Bell-metal is usually composed of three parts of copper and one part of tin. Its colour is greyish-white; it is very hard, sonorous, and elastic. The greater part of the tin may be separated by melting the alloy, and then pouring a little water on it. The tin decomposes the water, is oxidated, and thrown upon the surface.

The mirrors of telescopes are formed by melting together three parts of tin and one part of copper. This alloy is very hard, of the colour of steel, and admits of a fine polish. But besides this there are many other compounds used for the same purpose.

Vessels of copper, especially when used as kitchen-utensils, are usually covered with a thin coat of tin, to prevent the copper from oxidating, and to preserve the food which is prepared in them from being mixed with any of that poisonous metal. These vessels are then said to be tinned. Their interior surface is scraped very clean with an iron instrument, and rubbed over with sal ammoniac. The vessel is then heated, and a little pitch thrown into it, and allowed to spread on the surface. Then a bit of tin is applied all over the hot copper, which instantly assumes a silvery whiteness. The intention of the previous steps of the process is, to have the surface of the copper perfectly pure and metallic; for tin will not combine with the oxide of copper. The coat of tin thus applied is exceedingly thin. Bayen ascertained, that a pan nine inches in diameter, and three inches three lines in depth, when tinned, only acquired an additional weight of 21 grains. Nor is there any method of making the coat thicker. More tin indeed may be applied; but a moderate heat melts it, and causes it to run off.

6. Tin does not combine readily with iron. An alloy, however, may be formed, by fusing them in a close crucible, completely covered from the external air. We are indebted to Bergman for the most precise experiments on this alloy. When the two metals were fused together, he always obtained two distinct alloys; the first composed of 21 parts of tin and one part of iron; the second of two parts of iron and one part of tin. The first was very malleable, harder than tin, and not so brilliant; the second but moderately malleable, and too hard to yield to the knife.

The formation of tin-plate is a sufficient proof of the affinity between these two metals. This very useful alloy is formed by dipping into melted tin thin plates of iron, thoroughly cleaned by rubbing them with sand, and then steeping them 24 hours in water acidulated by bran or sulphuric acid. The tin not only covers the surface of the iron, but penetrates it completely, and gives the whole a white colour. See TINNING.

The affinities of tin, and its oxides, are, according to Bergman, as follow:

TIN.	OXIDE OF TIN.
Zinc,	Tartaric acid,
Mercury,	Muriatic,
Copper,	Sulphuric,
Antimony,	Oxalic,
Gold,	Arsenic,
Silver,	Phosphoric,
Lead,	Nitric,
Iron,	Succinic,
Manganese,	Fluoric,
Nickel,	Saclactic,
Arsenic,	Citric,
Platinum,	Lactic,
Bismuth	Acetic,
Cobalt,	Boracic,
Sulphur.	Prussic.

TIN-*stone*, an ore of tin which occurs in masses, in rounded pieces, and crystallized. These crystals are very irregular. Colour dark brown; sometimes yellowish grey, and sometimes nearly white. Somewhat transparent when crystallized. Specific gravity 6.9 to 6.97. Before the blowpipe it decrepitates, and on charcoal is partly reduced. Tinges borax white. According to Klaproth it is composed of

77.50	tin
21.50	oxygen
.25	iron
.75	silica
100.00	

TINCTURE. See PHARMACY.

TINCTURE, in heraldry, the hue or colour of any thing in coat-armour. See HERALDRY.

TINEA. See MEDICINE.

TINNING. Tinning is the art of covering any metal with a thin coating of tin. Copper and iron are the metals most commonly tinned. The use of tinning these metals is, to prevent them from being corroded by rust; as tin is not so easily acted upon by the air or water, as iron and copper are.

What are commonly called tin-plates, or sheets, so much used for utensils of various kinds, are in fact iron plates coated with tin.

The principal circumstance in the art of tinning is, to have the surfaces of the metal to be tinned perfectly clean and free from rust, and also that the melted tin may be perfectly metallic, and not covered with any ashes or calx of tin.

Tinning of iron. When iron plates are to be tinned, they are first scoured, and then put into what is called a pickle, which is sulphuric acid diluted with water; this dissolves the rust or oxyde that was left after scouring, and renders the surface perfectly clean. They are then again washed and scoured. They are now dipped into a vessel full of melted tin, the surface of which is covered with fat or oil, to defend it from the action of the air. By this means, the iron coming into contact with the melted tin in a perfectly metallic state, it comes out completely coated.

When a small quantity of iron only is to be tinned, it is heated, and the tin rubbed on with a piece of cloth, or some tow, having first sprinkled the iron with some powdered resin, the use of which is to reduce the tin that may be oxydated. Any inflammable substance, as oil for instance, will have in some degree the same effect, which is owing to their attraction for oxygen.

Tinning of copper. Sheets of copper may be tinned in the same manner as iron. Copper boilers, saucepans, and other kitchen utensils, are tinned after they are made. They are first scoured, then made hot, and the tin rubbed on as before with resin. Nothing ought to be used for this purpose but pure grain tin; but lead is frequently mixed with the tin, both to adulterate its quality, and make it lie on more easily; but it is a very pernicious practice, and ought to be severely reprobated.

To whiten brass or copper by boiling. Put the brass or copper into a pipkin with some white tartar, alum, and grain tin, and boil them together. The articles will soon become covered with a coating of tin, which, when well polished, will look like silver. It is in this manner that pins, and many sorts of buttons, are whitened.

TINNITUS AURIUM, a noise or buzzing in the ear, when it seems to receive sounds which do not exist, or at least which are not produced by the motion of the external air; and the ear being filled with a certain species of sound, cannot admit other sounds, unless they are very violent. The tinnitus is of two kinds, the one proceeding from a distemperature of the organ of hearing, the other from a disorder of the brain.

TIPHIA, a genus of insects of the order Hymenoptera. The generic character is, mouth with a membranaceous rounded jaw; the mandible arched and acute; no tongue; feelers four, filiform, unequal, and inserted in the middle of the lip; antennæ filiform, short, convolute; sting concealed within the abdomen. There are 27 species.

TIPULA, a genus of insects of the order Diptera. The generic character is, mouth arched over by the upper jaw extended from the head; palpi two, recurved, longer than the head; proboscis recurved, very short.

The larger kinds of tipulæ are, in general, distinguished by their lengthened bodies, horizontally expanded wings, and the unusual length and slenderness of their legs, which are also remarkably fragile; it being difficult to handle the insect without breaking some of its limbs. The smaller kind have incumbent wings, and in habit or general appearance are much allied to gnats, and some are so very small as scarcely to exceed the tenth of an inch in length. The larvæ of this genus differ in habit, according to their different modes of life, some being terrestrial, and others aquatic. They feed on the softer kind of vegetable substances, as the fine fibres of roots, &c. &c.

The largest of the European tipulæ, is the tipula rivosa of Linnæus, often measuring more than an inch and a half in body; and is distinguished by its wings, which are transparent, with large dusky undulations intermixed with white towards the rib or upper edge. This insect proceeds from a dusky or greyish larva of a lengthened form, and destitute of legs. It is found beneath the roots of grass in meadows, gardens, &c. and in the months of July and August changes into a lengthened and pointed chrysalis of a dusky colour, out of which in September proceeds the complete animal. This is popularly known by the title of long-legs, and is frequently seen in houses during the autumnal evenings, when it is remarkable for the propensity, in common with many other insects, of flying towards the flame of candles, and in consequence, often perishing in the blaze.

Tipula hortorum, or the garden tipula, is of somewhat smaller size than the preceding, and is produced from a larva and chrysalis of similar appearance with those of the former kind, but of a darker or blacker colour. The larva is found under grass-roots, &c. The wings of this species are transparent, with obscurely marked whitish variegations.

Tipula oleracea is a very common species, of nearly similar size with the preceding, and with transparent wings with a dusky rib or upper edge. Its larva inhabits garden-grounds, where it commits ravages among various plants. In its appearance it resembles those of the former kinds. It may be added, that the chrysalis, in most of the terrestrial insects of this tribe is furnished at the upper part with a pair of short hornlike processes, perhaps operating as a kind of spiracula; this particularity is however still more striking in those which belong to the aquatic kinds.

The tipula cornicina is of middle size, and has transparent wings with a marginal dusky spot, and the body yellow, with three longitudinal dusky streaks. Its larva, which is found in meadows, &c. is brown, with a flattened or truncated tail, beset with a certain number of radiating soft spines or processes; and the chrysalis is slender, and furnished, as in most others, with minute spines about its segments, by the assistance of which it is enabled to elevate itself to the surface when the time of its ultimate change takes place.

Tipula crocata is one of the few insects of this genus adorned with lively colours. It is of a polished black, with yellow rings round the abdomen.

Of those in which the wings are generally incumbent, the tipula plumosa, so named from its plumed antennæ, may serve as an example. This insect is of the size of a gnat, which it so much resembles in its general appearance as to be frequently mistaken for one: its colour is a greenish brown. The larva is aquatic, bears a considerable resemblance to those of the genus culex, as does likewise the chrysalis or pupa; which, instead of lying dormant during this state, is locomotive, playing about in the water, like the larva, and, at the time of its change, springs to the surface in order to give birth to the complete insect.

Among the very small tipulæ, none is more familiar than the elegant species called by Linnæus tipula phalænoides. This minute fly is very frequently observed in great numbers on windows during the decline of summer, appearing principally in the evening. It has so little the appearance of a genuine tipula, that it would hardly be considered as belonging to this genus by a common spectator. Its general length is about the tenth of an inch; and the wings, which are very large in proportion to the insect, are of an oval shape, and of a grey colour, elegantly mottled or variegated with dusky specks; the edges are deeply fringed with hair, and the nerves beset with oblong scales or feathers, and the whole insect, microscopically examined, exhibits a highly elegant appearance.

Tipula hirta so much resembles the last, that it might perhaps be rather considered as a variety or sexual difference than truly distinct. It is, however, a trifle larger, and of a darker colour. There can be little doubt that the larvæ of these minute species are aquatic, but they seem to be hitherto undescribed. There are 123 species.

TITANIUM, a metal found in black sand, resembling gunpowder, in Cornwall, and upon examination it is found to possess the following properties:

Its colour is orange-red, and it has a good deal of lustre. As it has been only obtained in very small agglutinated grains, neither its hardness, specific gravity, nor malleability, has been ascertained. It is one of the most infusible of metals, requiring a greater heat to melt it than can be produced by any method at present known.

When heated in the open air, it combines readily with oxygen, and seems capable of forming three different oxides; namely, the blue or purple, the red, and the white.

The protoxide, which is of a blue or purple colour, is formed, when titanium is exposed hot to the open air, evidently in consequence of the absorption of oxygen.

The deutoxide or red oxide is found native. It is often crystallized in four-sided prisms. Its specific gravity is about 4.2; and it is hard enough to scratch glass. When heated it becomes brown, and when urged by a very violent fire some of it is volatilized. When heated sufficiently along with charcoal, it is reduced to the metallic state.

The peroxide or white oxide may be obtained by fusing the red oxide in a crucible with four times its weight of potass, and dissolving the whole in water. A white powder soon precipitates, which is the white oxide of titanium. Vauquelin and Hecht have shown that it is composed of 89 parts of red oxide and 11 parts of oxygen.

Titanium does not seem to be capable of combining with sulphur.

Phosphuret of titanium has been formed by Mr. Chenevix by the following process: He put a mixture of charcoal, phosphat of titanium (phosphoric acid combined with oxide of titanium), and a little borax, into a double crucible, well luted, and exposed it to the heat of a forge. A gentle heat was first applied, which was gradually raised for three quarters of an hour, and maintained for half an hour as high as possible. The phosphuret of titanium was found in the crucible in the form of a metallic button. It is of a white colour, brittle, and granular, and does not melt before the blowpipe.

Vauquelin and Hecht attempted to combine it with silver, copper, lead, and arsenic, but without success. But they combined it with iron, and formed an alloy of a grey colour, interspersed with yellow-coloured brilliant particles. This alloy they were not able to fuse.

The affinities of the oxides of titanium are, according to professor Lampadius, as follows:

Gallic acid,	Sulphuric,
Phosphoric,	Muriatic,
Arsenic,	Nitric,
Oxalic,	Acetic.

TITHES, are the tenth part of the increase yearly arising and renewing from the profits of lands, the stock upon lands, and the personal industry of the inhabitants. And hence they are usually divided into three kinds; prædial, mixed, and personal.

Prædial tithes are such as arise merely and immediately from the ground, as grain of all sorts, hay, wood, fruits, herbs; for a piece of land or ground, being called in Latin prædium, whether it is arable, meadow, or pasture, the fruit or produce thereof is called prædial, and consequently the tithe payable for such annual produce is called a prædial tithe.

Mixed tithes are those which arise not immediately from the ground, but from things immediately nourished from the ground; as by means of cattle depastured thereupon, or otherwise nourished with the fruits; as colts, calves, lambs, chickens, milk, cheese, eggs.

Personal tithes are such as arise from the labour and industry of man, employing himself in some personal work, artifice, or negotiation; being the tenth part of the clear gain, after charges deducted. Watts, c. 59. But this is seldom paid in England, except by especial custom.

Tithes with respect to value, are divided into great and small. Great tithes, are corn, hay, wood. Small tithes, are the prædial tithes of all other kinds, together with those that are mixed, and personal.

Tithes of common right belong to that church, within the precincts of whose parish they arise. But one person may prescribe to have tithes within the parish of another; and this is what is called a portion of tithes.

No tithe is due de jure of the produce of a mine, or of a quarry, because this is not a fruit of the earth, renewing annually; but is the substance of the earth, and has perhaps been so for a great number of years. 1 Rol. Abr. 637.

But in some places tithes are due by custom of the produce of mines. 2 Vern. 46.

No tithe is due of lime: the chalk of which this is made being part of the soil. 1 Rol. Abr. 637.

Tithe is not due of bricks, which are made from the earth itself. 2 Mod. 77.

Nor is tithe due of turf, or of gravel; because both these are part of the soil. 1 Mod. 35.

It has been held, that no tithe is due of salt, because this does not renew annually. 1 Rol. Abr. 642.

But every one of these, and all things of the like kind, may by custom become tithable. 1 Rol. Abr. 642.

Barren land converted into tillage: no tithe shall be paid for the first seven years; but if it is not barren in its own nature, as if it is woodland, grubbed and made fit for tillage, tithes shall be paid presently; for woodland is fertile, not barren. 1 Rol. Abr.

Glebe lands, in the hands of the parson, shall not pay tithe to the vicar, nor being in the hands of the vicar, shall they pay tithe to the parson, because the church shall not pay tithes to the church. But if the parson lets his rectory, reserving the glebe lands, he shall pay the tithes thereof to the lessee. Gibs. 661.

No tithes are due for houses; for tithes are only due of such things as renew from year to year. 11 Rep. 16. But houses in London are, by decree, which was confirmed by an act of parliament, made liable to the payment of tithes. 2 Inst. 659. There is likewise in most antient cities and boroughs, a custom to pay tithes for houses; without which there would be no maintenance in many parishes for the clergy. 11 Rep. 16.

As to mills, it is now settled by a decree of the house of lords, upon an appeal from a decree of the court of exchequer, that only personal tithes are due from the occupier of a corn-mill. 2 Pere Will. Rep. 463.

The occupier of a new-erected mill, is liable to tithes, although such mill is erected upon land discharged of tithes. Cro. Jac. 429

Agistment, agisting in the strict sense of the word, means the depasturing of a beast the property of a stranger; but this word is constantly used, in the books, for depasturing the beast of an occupier of land, as well as that of a stranger. 5 Bac. Abr. An occupier of land is not liable to pay tithe for the pasture of horses, or other beasts, which are used in husbandry in the parish in which they are depastured; because the tithe of corn is by their labour increased. 1 Roll. Abr. 646. But if horses or other beasts are used in husbandry out of the parish in which they are depastured, an agistment tithe is due for them. 7 Mod. 114 No tithe is due for the pasture of milk-cattle which are milked in the parish in which they are depastured; because tithe is paid of the milk of such cattle. Lord Raym. 130. No tithe is due for the pasture of a saddle-horse which an occupier of land keeps for himself or servants to ride upon. Cro. Jac. 430.

An occupier of land is liable to an agistment tithe for all such cattle as he keeps for sale. Cro. Eliz. 446. Milk-cattle which are reserved for calving, shall pay no tithe for their pasture whilst they are dry; but if they are afterwards sold, or milked in another parish, an agistment tithe is due for the time they were dry. Lord Raym. 130. No tithe is due from an occupier of land for the pasture of young cattle, reared to be used in husbandry or for the pail. Cro. Eliz. 476. But if young beasts are sold before they come to such perfection as to be fit for husbandry, or before they give milk, an agistment tithe must be paid for them. Het. 86. If cattle also, which have neither been used in husbandry, nor for the pail, are, after having been kept some time, killed, to be spent in the family of the occupier of the land on which they are depastured, no tithe is due for their pasture. Jenk. 281.

No tithe is due for the cattle, either of a stranger or an occupier, which are depastured in grounds that have in the same year paid tithe of hay. 2 Rol. Rep. 191. But it is generally true, that an agistment tithe is due for depasturing any sort of cattle the property of a stranger. Cro. Eliz. 276. No agistment tithe is due for such beasts, either of a stranger or an occupier, as are depastured on the headlands of ploughed fields; provided that these are not wider, than is sufficient to turn the plough and horses upon. 1 Rol. Rep. 646. No tithe is due for such cattle as are depastured upon land that has the same year paid tithe of corn. Mod. 216. If land, which has paid tithe of corn one year, is left unsown the next year, no agistment is due for such land; because by this lying fresh, the tithe of the next crop of corn is increased. 1 Rol. Rep. 642. But if suffered to lie fallow longer than by the course of husbandry is usual, an agistment tithe is due for the beasts depastured upon such land. Shep. Abr. 1008.

Sheep, after paying tithe of wool, had been fed upon turnips not severed, by which they were bettered to the value of five shillings each, and were then sold; it also appeared, that before the next shearing time, as many had been bought in as were sold, and that of these tithe of wool had been paid. It was insisted, that if an agistment was to be paid for the sheep sold, it would be a double tithing; but the court held that this was a new increase, and decreed the defendant to account for an agistment tithe. Gibs. Rep. in Equi. 231. But in a later case the court held, that no agistment tithe should be paid, because sheep are animalia fructuosa. Bunb. 278.

Corn. It is held that no tithe is due of the rakings of corn involuntarily scattered. Cro. Eliz. 178. But if more of any sort of corn is fraudulently scattered, than there would have been scattered if proper care had been taken, tithe is due of the rakings of such corn. Cro. Eliz. 475. No tithes are due of the stubbles left in corn-fields, after mowing or reaping of corn. 2 Inst. 261.

Tithe of *hay* is to be paid, though beasts of the plough or pail, or sheep, are to be foddered with such hay. 12 Mod. 197. But no tithe is due of hay upon the headlands of ploughed grounds, provided that such headlands are not wider than is sufficient to turn the plough and horses upon. 1 Rol. Abr. 646. It is laid down in an old case, that if a man cuts down grass, and while it is in the swath carry it away, and gives it to his plough-cattle, not having sufficient sustenance for them otherwise, no tithe is due thereof. 1 Rol. Abr. 645. And in a modern case, the court of exchequer was of opinion, that no tithe is due of vetches, or of clover, cut green and given to cattle in husbandry. Rumb. 279.

Wood. Tithe of wood is not due in common right, because wood does not renew annually; but it was in antient times paid in many places by custom. 2 Inst. 645. Faggot wood, however, pays tithe.

Exemptions from tithes are of two kinds; either to be wholly exempted from paying any tithes, or from paying tithes in kind. The former is called de non decimando; the latter de modo decimandi.

Prescription de non decimando, is to be free from the payment of tithes, without any recompence for the same. Concerning which the general rule is, that no layman can prescribe in non decimando; that is, to be discharged absolutely of the payment of tithes, and to pay nothing in lieu thereof; unless he begins his prescription in a religious or ecclesiastical person. But all spiritual persons, as bishops, deans, prebendaries, parsons, and vicars, may prescribe generally in non decimando. 1 Rol. Abr. 653.

A modus decimandi, usually called by the name of modus only, is where there is by custom a particular manner of tithing, different from the general laws of taking tithes in kind. This is sometimes a pecuniary compensation, as so much an acre for the tithe of land; sometimes a compensation in work and labour; as that the parson shall have only the twelfth cock of hay, and not the tenth, in consideration of the owner's making it for him; sometimes in lieu of a large quantity, when arrived to great maturity; as a couple of fowls in lieu of tithe-eggs, &c. Any means in short, whereby the general law of tithing is altered, and a new method of taking them is introduced, is called modus decimandi, or special method of tithing. 2 Black. 29.

In order to make a modus or prescription good, several qualifications are requisite. It must be supposed to have had a reasonable commencement; as that at the time of the composition, the modus was the real value of money, though now become much less. It must be something for the parson's benefit; therefore the finding straw for the body of the church, the finding a rope for a bell, the paying 5*s.* to the parish-clerk, have been adjudged not to be good. But it is a good modus to be discharged, that one has time out of mind been used to employ the profits for the repair of the chancel, for the parson has a benefit by that.

A modus must be certain; so a prescription to pay a penny or thereabouts, for every acre of land, is void for the uncertainty. And it has been held, that if a precise day of payment is not alleged, the modus will be ill; but now it is holden, that where an amenial modus has been paid, and no certain day for the payment thereof is limited, the same shall be due and payable on the last day of the year.

A modus must be antient; and therefore if it is any thing near the value of the tithe, it will be supposed to be of late commencement, and for that reason will be set aside.

A modus must be durable: for the tithe in kind, being an inheritance certain, the recompence for it should be as durable; therefore a certain sum, to be paid by the inhabitants of such a house, has been set aside, because the house may go down and none inhabit it.

And it must be constant and uninterrupted; for if there have been frequent interruptions, no custom or prescription can be obtained. But after it has been once duly obtained, a disturbance for ten or twenty years shall not destroy it.

When a common is divided and inclosed, a modus shall only extend to such tithes as the common yielded before inclosure; such as the tithes of wool, lambs, or agistment; but not to the tithes of hay and corn, which the common, whilst it was common, did never produce. Bur. 1735.

The parson cannot come himself and set out his tithe without the consent of the owner; but he may attend and see it set out; yet the owner is not obliged to give him notice when he intends to set it out, unless by special custom. Id. 1891. After it is set out, the care thereof as to wasting or spoiling, rests upon the parson, and not upon the owner of the land; but the parson may spread, dry, and prepare his corn, hay, or the like, in any convenient place upon the ground, till it is sufficiently weathered, and fit to be carried into the barn. And he may carry his tithes from the ground, either by the common way, or such other way as the owner of the land uses to carry away his nine parts. If the parson suffers his tithe to stay too long upon the land, the other may distrain the same as doing damage, or he may have an action on the case; but he cannot put in his cattle and destroy the corn or other tithe, for that would be to make himself judge what shall be deemed a convenient time for taking it away. Lord Raym. 189.

Payment of tithes. By 1 Geo. I. c. 6, all customary payments due to clergymen, the payment of tithes, &c. are enforced; and the prosecution in this case may be for any tithes or church-rates, or any customary or other rights, dues, or payments, belonging to any church or chapel, which of right by law and custom ought to be paid for the stipend or maintenance of any minister or curate, officiating in any church or chapel, provided that the same does not exceed 20*l.* But the time is not limited, within which the same shall become due.

And if any quaker shall refuse to pay or compound for the same, any parson, vicar, curate, farmer, or proprietor of such tithes, or any churchwarden, chapelwarden, or other person who ought to have, receive, or collect any such tithes, rates, dues, or payments, may make complaint to any two justices, other than such as is patron of the church or chapel, or interested in the tithes. The number of days is not limited between the time of refusal and the complaint; nor is it hereby required that such complaint shall be in writing. But it will be more conformable to the usual practice in like cases, if it is in writing. Upon which complaint, the said justices are required to summon in writing, under their hands and seals, by reasonable warning, such quaker, against whom such complaint shall be made. And after appearance, or on default of appearance (the warning or summons being proved before him upon oath), they may proceed to examine on oath the truth of the complaint, and to ascertain and state what is due and payable; and by order under their hands and seals, they may direct and appoint the payment thereof, so that the sum, ordered as aforesaid, does not exceed 10*l.*; and also such costs and charges, that upon the merits of the cause shall appear, not exceeding 10*s.*; and on refusal to pay, any one of the two next justices, by warrant under his hand and seal, may levy the same by distress and sale, rendering the overplus, the necessary charges of distraining being first deducted and allowed by the said justice, unless it is in the case of appeal, and then no warrant of distress shall be granted till the appeal shall be determined. Tithes under the value of 40*l.* may also be recovered by the same process from persons who are not quakers. As no time is limited for detaining the distress, nor charges allowed for keeping it, it may be sold immediately.

Any person who shall think himself aggrieved by the judgment of the two justices, may appeal to the next session; where if the judgment shall be affirmed, they shall decree the same by order of session, and give costs against the appellant, to be levied by distress and sale, as to them shall seem reasonable; and no proceeding herein shall be removed by certiorari, or otherwise, unless the title of such tithes shall be in question.

The withholding of tithes from the parson or vicar, whether the former is a clergyman or lay-appropriator, is among the pecuniary causes cognizable in the ecclesiastical court; but herein a distinction must be taken: for the ecclesiastical courts have no jurisdiction to try the right of tithes, unless between spiritual persons, between spiritual men and laymen, and are only to compel the payment of them when the right is not disputed. 2 Inst. 364.

Tithes, however, if of any considerable value, are generally sued for in the exchequer by English bill, except where the suit is founded on the statute of 2 and 3 Ed. VI. for double or treble value, &c.

TITHINGMEN. In the Saxon times, for the better conservation of peace, and the more easy administration of justice, every hundred was divided into ten districts or tithings, each tithing consisting of ten friborgs, each friborg of ten families; in which tithingmen, or civil deans, were to examine and determine all smaller differences between villages and neighbours, but to refer all greater matters to the superior courts, which had a jurisdiction over the whole hundred.

TITLE, in law, denotes any right which a person as to the possession of a thing; or an authentic instrument, whereby he can prove his right. See RIGHT, &c.

As to the titles of the clergy, they denote certain places wherein they may exercise their functions. There are several reasons why a church is called titulus; but that which seems to be the best, is because antiently the name of the saint to whom the church was dedicated, was engraved on the porch, as a sign that the saint had a title to that church; and thence the church itself was afterwards called titulus. In this sense a title signifies the church to which a clergyman was admitted, and where he is constantly to reside; and by the canons, none shall be ordained without a title. This is in order to keep out such from the ministry who, for want of maintenance, might bring a disgrace upon the church. Can. 31.

In short, according to some writers, such a title is an assurance of being preferred to an ecclesiastical benefice; that is to say, a certificate that the clerk is provided of some church or place, or where the bishop that ordains him, intends shortly to admit him to a benefice or curacy then void.

TITMOUSE. See PARUS.

TMESIS, in grammar, a figure whereby a compound word is separated into two parts, and one or more words placed between them: thus, for quæcunque, Virgil says, quæ me cunque vocant terræ, &c.

TOAD. See RANA.

TOBACCO. See NICOTIANA.

TODUS, the *tody*, in ornithology, a genus belonging to the order of picæ. The beak is slender, depressed, broad, and the base beset with bristles; the nostrils are small and oval; the toes are placed three before and one behind; the middle are connected to the outer. There are 15 species according to Dr. Latham. "Birds of this genus (says that eminent ornithologist) inhabit the warmer parts of America. They vary considerably in their bills as to breadth, but all of them have a certain flatness, or depression, which is peculiar. They have a great affinity to the flycatchers; and, indeed, to speak the truth, the two genera run much into one another. However, in one thing they differ materially; for in the tody, the outer and middle toes are much connected, whereas in the flycatcher genus they are divided to their origin."

TOLUIFERA, the *balsam* of *tolu-tree*, a genus of plants of the class decandria, and order monogynia. The calyx is five-toothed, bell-shaped; petals five, obcordate; style none. There is only one species, the balsamum. This tree grows to a considerable height: it sends off numerous large branches, and is covered with rough, thick, greyish bark; the leaves are elliptical or ovate, entire, pointed, alternate, of a light-green colour, and stand upon short strong footstalks; the flowers are numerous, and produced in lateral racemi.

It grows in Spanish America, in the province of Tolu, behind Carthagena, whence we are supplied with the balsam. This balsam is obtained by making incisions in the bark of the tree, and is collected into spoons, which are made of black wax, from which it is poured into proper vessels.

This balsam is of a reddish-yellow colour, transparent, in consistence thick and tenacious. By age it grows so hard and brittle, that it may be rubbed into a powder between the finger and thumb. Its smell is extremely fragrant, somewhat resembling that of lemons. Its taste is warm and sweetish, and on being chewed, it adheres to the teeth. See BALSAMS.

This balsam possesses the same general virtues with the balsam of Gilead, and that of Peru. It is, however, less heating and stimulating, and may therefore, be employed with more safety. It has been chiefly used as a pectoral, and is said to be an efficacious corroborant in gleets and seminal weaknesses. It is directed by the Pharmacopœias in the syrupus tolutanus, tinctura tolutana, and syrupus balsamicus.

TOMBAC, a metal composed of copper and arsenic. See ARSENIC.

TOMERS, a genus of the class and order dodecandria monogynia. The involute is four or five-leaved; calyx none; corolla five-petalled; nect. scales five; berry one-seeded. There are three species, of which the sabipere or tallow-tree of China is the most remarkable. The leaves and twigs of this tree abound in a viscid juice, and being bruised and macerated in water, render it glutinous, and it is used by the natives to work up their plaister. A great quantity of thick white oil is extracted from the berries, of which candles are made resembling wax or spermaceti.

TON weight, 20 hundred. See WEIGHT.

TONE, or TUNE, in music, a property of sound whereby it comes under the relation of grave and acute; or it is the degree of elevation any sound has, from the degree of swiftness of the vibrations of the parts of sonorous bodies. See SOUND,

Tone is more particularly used for a certain degree or interval of tune, whereby a sound may be either raised or lowered from one extreme of a concord to the other, so as still to produce true melody.

TONGUE. See ANATOMY.

TONNAGE, a custom or impost due for merchandize brought or carried in tons from or to other nations after a certain rate in every ton.

TONNAGE. The usual method of finding the tonnage of any ship is by the following rule:—Multiply the length of the keel by the breadth of the beam, and that product by half the breadth of the beam: and divide the last product by 94, and the quotient will be the tonnage.

Ship's keel 72 feet; breadth of beam 24 feet.

$$\frac{72 \times 24 \times 12}{94} = 120.6 \text{ tonnage.}$$

The tonnage of goods and store is taken sometimes by weight, and sometimes by measurement; and that method is allowed to the vessel which yields the most tonnage. In tonnage by weight, 20 cwt. make 1 ton. In tonnage by measurement, 40 cubic feet are equal to 1 ton. All carriages, or other stores to be measured by tonnage, are taken to pieces, and packed in the manner which will occupy the least room on board ship. All ordnance, whether brass or iron, is taken in tonnage by its actual weight. Musket-cartridges in barrels or boxes, all ammunition in boxes, and other articles of great weight, are taken in tonnage according to their actual weight.

The following is the tonnage allowed to the military officers of the ordnance embarked for foreign service, for their camp-equipage and baggage:

For a field officer	-	5 tons.
For a captain	-	3 do.
For a subaltern	-	1½ do.

TONSELLA, a genus of the class and order triandria monogynia. The calyx is five-parted; petals five; nect. pitcher-shaped; berry one-celled, four-seeded. There are two species, trees of the West Indies.

TONSILS. See ANATOMY.

TONSURE, in ecclesiastical history, a particular manner of shaving or clipping the hair of ecclesiastics or monks.

The antient tonsure of the clergy was nothing more than polling the head, and cutting the hair to a moderate degree, for the sake of decency and gravity; and the same observation is true, with respect to the tonsure of the antient monks. But the Romanists have carried the affair of tonsure much farther; the candidate for it kneeling before the bishop, who cuts his hair in five different parts of the head, viz. before, behind, on each side, and on the crown.

TONTINE, a species of increasing annuity on which money is sometimes borrowed, either for the service of the state, or for erecting bridges, churches, theatres, taverns, and other expensive buildings. It is usually divided into a certain number of shares, for each of which a life is nominated; and a certain annual sum being set apart for payment of interest on the money advanced, the same sum is to continue to be annually divided among the surviving nominees, by which means their annuities increase as the number of shares are reduced, till the whole are extinct.

The first attempt in this country to raise money for the public service on this uncertain kind of interest, was in 1693; but though in this instance the annuity was more determinate than in the generality of such plans, as the subscribers were certain of 10 per cent. for the first seven years, it did not succeed, only 108,100*l*. being advanced out of a million intended to be raised.

In 1757, an attempt was made to raise a loan by a tontine scheme; and in 1765, a tontine formed part of a project for funding navy and victualling bills; both these plans were unsuccessful; and the tontine formed in the year 1789, which was the last attempt to raise a public loan in this way, experienced a similar fate, as not half the proposed number of shares were disposed of.

A variety of tontine schemes for short periods of five or seven years, have of late been set on foot, to the delusion of those who have been induced to subscribe to them.

Mr. W. Morgan has shewn the folly of these speculations. He observes, that in the short term of seven years, the accumulation of money at simple and compound interest, is much the same, and the decrements of life are so inconsiderable, as to produce little or no effect in increasing this accumulation. A weekly payment of sixpence improved at 4 per cent. compound interest for seven years, will amount to 10*l*. 5*s*. 3*d*. but at simple interest it will amount to 10*l*. 3*s*. 10*d*., and at no interest at all, to 9*l*. 2*s*. The addition, therefore, to the principal from the mere operation of compound interest, is so inconsiderable, that were all the subscribers to live to the end of the term, each share would be increased by this means only 1*l*. 3*s*. 7*d*. With respect to the advantage arising from survivorship, let it be supposed that the number of subscribers to the tontine is 10,000, consisting of persons of all ages under 60 years. According to the table of probabilities of life at Northampton, 8647 of those persons will survive a term of seven years; so that if the whole 10,000 lived to make their last payment, and none of them died till just before the final distribution of the stock, the share of each survivor would be no more than 11*l*. 17*s*. 6*d*. But it is to be observed, that these lives will be continually dying from the time of the first subscription to the conclusion of the tontine; and that these deaths, by lessening the weekly contributions, will reduce the share of each survivor to 11*l*. 11*s*. nearly. When the expences of management are also deducted, and allowance is made for the loss which may be sustained by investing the money in the public funds, it is more than probable that the shares will fall greatly below the sum just stated, and that the surviving members will, at the end of seven years, have the mortification of finding that they barely receive the money they have paid, after having endangered the loss of the greatest part of it by dying in the mean time. In several of these schemes, which have lately expired, the division to the subscribers has been considerably less than the amount of their contributions.

TOOTH. See ANATOMY.

TOPASFELS. See ROCKS, *primitive*.

TOPAZ. The name topaz has been restricted by Mr. Hauy to the stones called by mineralogists occidental ruby, topaz, and sapphire; which, agreeing in their chrystallization and most of their properties, were arranged under one species by Mr. Romé de Lisle. The word topaz, derived from an island in the Red Sea, where the antients used to find topazes, was applied by them to a mineral very different from ours. One variety of our topaz they denominated chrysolite.

The topaz is found in Saxony, Bohemia, Siberia, and Brazil, mixed with other minerals in granite rocks.

It is commonly chrystallized. The primitive form of its crystals is a prism whose sides are rectangles, and bases rhombs, having their greatest angles 124° 22′, and the internal molecule has the same form; and the height of the prism is to a side of the rhomboidal bases as 3 to 2. The different varieties of topaz crystals hitherto observed, amount to 6. Five of these are eight-sided prisms, terminated by four-sided pyramids, or wedge-shaped summits, or by irregular figures of 7, 13, or 15 sides: the last variety is a twelve-sided prism, terminated by six-sided pyramids wanting the apex. For an accurate description and figure of these varieties, the reader is referred to Mr. Hauy.

The texture of the topaz is foliated. It causes a double refraction. Specific gravity from 3.46 to 3.56. The Siberian and Brazil topazes, when heated, become positively electrified on one side, and negatively on the other. It is infusible by the blowpipe. The yellow topaz of Brazil becomes red when exposed to a strong heat in a crucible; that of Saxony becomes white by the same process. This shews us that the colouring matter of these two stones is different.

The colour of the topaz is various, which has induced mineralogists to divide it into the following varieties:

1. Red topaz, of a red colour, inclining to yellow; called Brazilian or occidental ruby.

2. Yellow topaz, of a golden-yellow colour, and sometimes also nearly white; called occidental or Brazil topaz. The powder of this and the following variety, causes syrup of violets to assume a green colour.

3. Saxon topaz. It is of a pale wine yellow colour, and sometimes greyish white.

4. Aigue marini, of a bluish or pale-green colour.

5. Occidental sapphire, of a blue colour, and sometimes white.

A specimen of white Saxon topaz, analyzed by Vauquelin, contained

68	alumina
31	silica
99.	

TOPOGRAPHY, a description or draught of some particular place, or small tract of land, as that of a city or town, manor or tenement, field, garden, house, castle, &c. such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

TORDYLIUM, *hart-wort*, in botany, a genus of plants of the class pentandria, and order digynia, and in the natural system arranged under the 45th order, umbellatæ. The corollets are radiated, and all hermaphrodite; the fruit is roundish, and crenated on the margin; the involucra long and undivided. There are seven species; of which two are British, the maximum and officinale. 1. The maximum, or knotted parsley, has simple sessile umbels, the exterior seeds being rough. It grows in the borders of the corn-fields, and in dry stony places. 2. The officinale, officinal hart-wort, has partial involucra, as long as the flowers; leaflets oval and jagged; the seeds are large and flat, and their edges notched.

TORMENTILLA, Tormentil, a genus of plants of the class icosandria, and order polygynia, and in the natural system ranging under the 35th order, senticosæ. The calyx is octofid; the petals are four; the seeds round, naked, and affixed to a juiceless receptacle. There are two species, the erecta and repens, both indigenous. The erecta, common tormentil, or septoil, has a stalk somewhat erect, and sessile leaves. The roots consist of thick tubercles, an inch or more in diameter, replete with a red juice of an astringent quality. They are used in most of the Western Islands.

TORNADO, or Turnado, a sudden and vehement gust of wind from all points of the compass, frequent on the coast of Guinea.

A tornado seems to partake much of the nature of a whirlwind or perhaps of a water-spout, but is more violent in its effects. It commences very suddenly, several clouds being previously drawn together, when a spout of wind, proceeding from them, strikes the ground, in a round spot of a few rods or perches diameter, in the course of the wind of the day, and proceeds thus half a mile or a mile. The proneness of its descent makes it rebound from the earth, throwing such things as are moveable before it, but some sideways or in a lateral direction from it. A vapour, mist, or rain descends with it, by which the path of it is marked with wet.

The gentleman who furnishes the above general description, gives an account of one which happened a few years since at Leicester, about fifty miles from Boston, in New England. "It happened in July, on a hot day, about four o'clock in the afternoon. A few clouds having gathered westward, and coming overhead, a sudden motion of their running together in a point being observed, immediately a spout of wind struck the ground at the west end of a house, and instantly carried it away with a negro man in it, who was afterwards found dead in the path of it. Two men and a woman, by the breach of the floor, fell into the cellar; and one man was driven forcibly up into the chimney-corner. These were preserved, though much bruised; they were wet with a vapour or mist, as were the remains of the floor, and the whole path of the spout. This wind raised boards, timbers, &c. A joist was found on one end, driven near three feet into the ground. The spout probably took it in its elevated state, and drove it forcibly down. The tornado moved with the celerity of a middling wind, and constantly declined in strength till it entirely ceased."

TORPEDO. See Raia, and Electricity.

TORRICELLIAN experiment, a famous experiment made by Torricelli, a disciple of the great Galileo, which has been already explained under Barometer.

TORRID zone, among geographers, denotes that tract of the earth lying upon the equator, and on each side as far as the two tropics, or 23° 30′ of north and south latitude.

TORTOISE-shell, the shell of the testaceous animal called a tortoise; used in inlaying, and in various other works, as for snuff-boxes, combs, &c. Mr. Catesby observes, that the hard strong covering which incloses all sorts of tortoises, is very improperly called a shell; being of a perfect bony contexture, but covered on the outside with scales, or rather plates of a horny substance; which are what workmen call tortoise-shell. See Horn.

There are two general kinds of tortoises, viz. the land and sea tortoise, testudo terrestris and marina. The sea-tortoise, again, is of several kinds; but it is the testudo imbricata of Linnæus, alone which furnishes that beautiful shell so much admired in Europe. See Testudo.

The whole spoils of the tortoise consist in thirteen leaves or scales, eight of them flat, and five a little bent. Of the flat ones, there are four large ones, sometimes a foot long, and seven inches broad. The best tortoise-shell is thick, clear, transparent, of the colour of antimony, sprinkled with brown and white. When used in marquetry, &c. the workmen give it what colour they please by means of coloured leaves, which they put underneath it.

Working and joining of tortoise-shell.—Tortoise-shell and horn become soft in a moderate heat, as that of boiling water, so as to be pressed, in a mould, into any form, the shell or horn being previously cut into plates of a proper size. Plumier informs us, in his Art de Tourner, that two plates are likewise united into one by heating and pressing them; the edges being thoroughly cleaned, and made to fit close to one another. The tortoise-shell is conveniently heated for this purpose by applying a hot iron above and beneath the juncture, with the interposition of a wet cloth to prevent the shell from being scorched by the irons: these irons should be pretty thick, that they may not lose their heat before the union is effected. Both tortoise-shell and horns may be stained of a variety of colours, by means of the colouring drugs commonly used in dyeing, and by certain metallic solutions.

TOUCAN. See Ramphastos.

Toucan, in astronomy, a constellation of the southern hemisphere, consisting of eight small stars, and otherwise called anser americanus. See Astronomy.

TOUCH-needle, among assayers, refiners, &c. little bars of gold, silver, and copper, combined together in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the mark it leaves on the touchstone, with those of the bars. The metals usually tried by the touchstone, are gold, silver, and copper, either pure, or mixed with one another in different degrees and proportions, by fusion. In order to find out the purity or quantity of baser metal in these various admixtures, when they are to be examined, they are compared with these needles, which are mixed in a known proportion, and prepared for this use. The metals of these needles, both pure and mixed, are all made into laminæ or plates, one-twelfth of an inch broad, and a fourth part of their breadth in thickness, and an inch and a half long; these being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it. The black rough marbles, the basaltes, or other softer kinds of black pebbles, are the most proper for touchstones.

The method of using the needles and stone is this: The piece of metal to be tried, ought first to be wiped well with a clean towel, or piece of soft leather, that you may the better see its true colour; for from this alone an experienced person will, in some degree, judge beforehand what the principal metal is, and how and with what debased. Then chuse a convenient, not overlarge, part of the surface of the metal, and rub it several times very hardly and strongly against the touchstone; that in case a deceitful coat or crust should have been laid upon it, it may be worn off by that friction: this, however, is more readily done by a grindstone, or small file, if you have them at hand. Then wipe a flat and very clean part of the touchstone, and rub against it, over and over the surface of the piece of metal, till you have, on the flat surface of the stone, a thin metallic crust, an inch long, and about an eighth of an inch broad; this done, look out the needle that seems most like the metal under trial, wipe the lower part of this needle very clean, and then rub it against the touchstone as you did the metal, by the side of the other line, and in a direction parallel to it. When this is done, if you find no difference between the colours of the two marks made by your needle and the metal under trial, you may, with great probability, pronounce that metal and your needle to be of the same alloy, which is immediately known by the mark engraved on your needle. But if you find a difference between the colour of the mark given by the metal, and that by the needle you have tried, choose out another needle, either of a darker or lighter colour than the former, as the difference of the tinge on the touchstone directs; and by one or more trials of this kind you will be able to determine which of your needles the metal answers, and thence what alloy it is of, by the mark of the needle; or else you will find that the alloy is extraordinary, and not to be determined by the comparison of your needles.

TOURMALINE, in mineralogy, a species of siliceous earth. It has been found only in Ceylon, Brazil, and Tyrol. That of Ceylon is of a dark-brown or yellowish colour; its specific gravity 3.065, or 3.295; that of Brazil is green, blue, red, or yellow, and its specific gravity 3.075 or 3.180; that of Tyrol by reflected light is of a blackish brown, but by refracted light yellowish, or in thin pieces green; its specific gravity 3.050; mostly crystallised in polygonal prisms, but sometimes amorphous. The thickest parts are opake; the thin more or less transparent. See SHORL.

TOURNEFORTIA, a genus of the pentandria monogynia class of plants, the flower of which consists of a single petal, in form of an oval tube, longer than the calyx, divided into five slight segments somewhat broad and pointed, and spread open; the fruit is a globose berry, containing two cells: and the seeds are of an oval figure, two in number, and separated by the pulp. There are eleven species, shrubs of South America.

TOURNEQUET. See SURGERY.

TOURRETTIA, a genus of the didynamia angiospermia class and order. The cal. is two-lipped; cor. lower lip none; caps. echinate, four-celled, two-valved. There is one species, an annual of Peru.

TOWER, any high building raised above another, consisting of several stories, usually of a round form, though sometimes square or polygonal; a fortress, a citadel. Towers are built for fortresses, prisons, &c. as the tower of the Bastile, which was destroyed by the inhabitants of Paris in 1789.

The tower of London, commonly called The Tower, is a building with five small turrets at different angles above it, situated on the banks of the river Thames. The guards usually do duty in it. It is at present garrisoned by the invalids. The tower of London is not only a citadel to defend and command the city, river, &c. but it is also a royal palace, where the kings of England with their courts have sometimes lodged; a royal arsenal, wherein are stored arms and ammunition for sixty thousand soldiers; a treasury for the jewels and ornaments of the crown; a mint for coining money; the archives wherein are preserved all the antient records of the courts of Westminster, &c. and the chief prison for state delinquents. The officers belonging to the tower of London consist of

	per annum.		
1 Constable and chief governor, at	£1000	0	0
1 Lieutenant governor, at	700	0	0
1 Deputy lieutenant, at	365	0	0
1 Major, at	182	10	0
1 Chaplain, at	121	13	4
1 Gentleman porter, at	84	6	8
1 Gentleman gaoler, at	70	0	0
1 Physician, at	182	10	0
1 Surgeon, at	45	12	6
1 Apothecary, 1 yeoman porter.			

Tower-bastions, in fortification, are small towers made in the form of bastions, by M. Vauban, in his second and third method; with rooms or cellars underneath to place men and guns in them.

Towers, moveable, in antient military history, were three stories high, built with large beams: each tower was placed on four wheels or trucks, and towards the town covered with boiled leather, to guard it from fire, and to resist the darts; on each story one hundred archers were posted. They were pushed with the force of men towards to the city wall. From these the soldiers, placed in the different stages, made such vigorous discharges that none of the garrison dared to shew themselves on the rampart.

TOXICODENDRON, the *poison-wood*. See RHUS.

TOZZIA, a genus of the didynamia angiospermia class of plants, with a monopetalous ringent flower; the upper lip of which is bifid, and the lower one trifid; the fruit is a globose unilocular capsule, containing an ovated seed. One species.

TRACHEA. See ANATOMY.

TRACHELIUM, a genus of the pentandria monogynia class of plants, with a funnel-fashioned flower, divided into five segments at the limb; the fruit is a roundish obtusely trilobous capsule, containing a great number of very minute seeds. There are three species, herbs of the Levant.

TRACHICHTHYS, a genus of fishes of the order thoracici. The generic character is, head rounded in front; eyes large; mouth wide, toothless, descending; gill-membrane with eight rays, the four lowermost of which are rough on the edges; scales rough; abdomen cataphracted with large carinate scales. There is only a single species, viz. the australis, that inhabits New Holland, about five inches long, and two deep; body coated with scales so strongly and closely inserted, that it is not possible to detach one from the rest without bringing with it a portion of the skin.

TRACHINUS, WEEVER, a genus of fishes of the order jugulares: the generic character is, head slightly roughened, compressed; gill-membrane six-rayed; gill-covers serrated on the edge; body compressed, vent situated near the breast.

1. Trachinus draco, dragon weever. This fish is of a lengthened shape, much compressed on the sides, and covered with small and easily deciduous scales; the mouth is wide, and opens vertically, like that of the star-gazer; both jaws are armed with sharp teeth; the tongue is straight, smooth, and pointed; the eyes are seated on the upper part of the head, pretty near each other; the gill-covers are armed at their tips with a strong spine. The general colour of the weever is silvery, with a yellowish or dusky cast on the upper parts, while the sides are commonly varied by numerous obliquely transverse streaks of a similar colour; the scales are small and rounded; the first dorsal fin is of a deep black. The usual length of the fish is about ten or twelve inches.

This fish is an inhabitant of the Mediterranean and Northern seas, commonly frequenting the coasts, and frequently imbedding itself in the sand; in which situation, if accidentally trodden on, it strikes backwards with great violence, and endeavours to wound the aggressor with the spines of its first dorsal fin. So troublesome are the consequences arising from the punctures inflicted by this part, that a law is said to exist in France, obliging the fishermen to cut it away before the fish is exposed for sale. The usual symptoms attending the wound are, violent heat, pain, and inflammation; and it not unfrequently happens that when the hand is thus wounded, a sudden redness extends throughout the whole length of the arm, as far as the shoulder. The usual remedy among the English fishermen is, according to Mr. Pennant, sea-sand, well rubbed on the part: an application which one might at first suppose would rather aggravate than alleviate the complaint. Many other popular remedies are used in different countries. Notwithstanding the suspicious aspect of the above-mentioned black fin, it does not seem to have any thing in its conformation which can justify the idea of any poisonous fluid conveyed from it into the wound; the spines when microscopically examined shewing no appearance of a tubular structure.

The weever is considered as an excellent article of food, and is much esteemed in Holland, France, &c. It feeds principally on marine insects, worms, and small fishes; it is tenacious of life, and can exist many hours out of water; the skin is remarkably tough, and the animal may be excoriated with almost the same facility as an eel. See Plate Nat. Hist. fig. 403.

2. Trachinus osbeckii, osbeckian weever. Native of the Atlantic seas, and found about the isle of Ascension, &c. Colour white, spotted with black; both jaws of equal length, and furnished with several rows of long and pointed teeth, three of which, both above and below, are larger than the rest: some sharp teeth are also situated in the throat: each gill-cover is terminated by two spines of unequal length; tail even. Described by Osbeck in his Voyage to China. There are no other species.

TRADE, the practice of exchanging goods, wares, money, bills and other articles of value, with the view of advantage or profit. It is generally distinguished into foreign trade, or the export and import of commodities to and from other countries, and the internal or home trade, or that which is carried on within the country, which two branches, however, are rather distinct in appearance than reality; for a very considerable portion of the internal trade, arising from manufactures carried on to supply foreign markets, could not subsist without foreign commerce, while a large part of the returns for manufactures sent abroad, being articles for consumption or raw materials which are converted to use in the different manufactures, depends upon our internal trade, so that the one supports the other, and by their mutual connection and dependance, the foreign and the domestic trade of Great Britain have risen together to their present unparalleled height.

The extent and value of the principal branches of foreign trade have been stated under the article COMMERCE, and the following view of the present state of the principal manufactures will shew the vast importance of our internal or home trade; a general proof of the advancement of which, may be found in the great increase in the number of country banks, now spread all over the kingdom, deriving their profits chiefly from this part of its trade.

Manufactures may be defined the arts by which natural productions are brought into the state or form in which they are consumed or used. The principal manufactures are those which fabricate the various articles of clothing; as the woollen-manufacture, the leather-manufacture in part, the cotton-manufacture, the linen-manufacture, and the silk-manufacture; others supply articles of household furniture, as the manufactures of glass, porcelain, earthenware, and of most of the metals in part; the iron-manufacture furnishes implements of agriculture, and weapons of war; and the paper-manufacture supplies a material for communicating ideas and perpetuating knowledge.

The enhanced value of raw materials by manufacture has been illustrated by the following remarks: "One hundred pounds laid out in wool, and that wool manufactured into goods for the Turkey market, and raw silk brought home in return, and manufactured here, will increase that one hundred to five thousand pounds; which quantity of silk-manufactures being sent to New Spain, would return ten thousand pounds; which vast improvement of the first hundred pounds, becomes, in a few years, dispersed amongst all orders and degrees, from the prince to the peasant. Thus, again, a parcel of iron-stone, which when taken from its natural bed, was not worth five shillings, when made into iron and steel, and thence into various manufactures for foreign markets, may probably bring home to the value of ten thousand pounds; for steel may be made near three hundred times dearer than standard gold, weight for weight. Twenty acres of fine flax, when manufactured into the dearest and most proper goods for foreign markets, may, in return, bring what may be worth ten thousand pounds; for an ounce of the finest Flanders thread has been sold in London for four pounds, and such an ounce made in Flanders into the finest lace, may be here sold for forty pounds; which is above ten times the price of standard gold, weight for weight."

Manufactures had begun to flourish in different parts of Europe, long before they were attempted in Britain; the few articles of this description which were in request, being obtained in exchange for wool, hides, tin, and such other produce as the country in a very uncultivated state could supply. In 1337, it was enacted, that no more wool should be exported; that no one should wear any but English cloth; that no cloths made beyond seas should be imported; that foreign clothworkers might come into the king's dominions, and should have such franchises as might suffice them. Before this time, the English were little more than shepherds and wool-sellers.

The progress of improvement since the establishment of manufactures in this country, has in most instances been remarkably great, particularly of late years, in consequence of an increased knowledge of the properties of various materials, vast improvements in all kinds of machinery, and the great capitals invested in most of the different branches. The value of British manufactures exported to all countries, on an average of six years, ending with 1774, was 10,342,019*l.*; the American war suspended for a time an important market for several of our manufactures, in consequence of which the total amount exported had fallen in 1781 to 7,633,332*l.* and on an average of six years, ending with 1783, was 8,616,660*l.* During the peace which followed, the export trade rapidly revived, and, in the year preceding the war with France, had attained to a magnitude beyond all former example; it was checked a little by the mercantile embarrassments in 1793, but a few years after, the unsettled state of several of the principal European powers threw many additional branches of foreign trade into the hands of our merchants, and carried the export of our manufactures to its present important extent.

Official value of British produce and manufactures exported from Great Britain, for eighteen years, ending 5th January, 1806:

In 1788	£12,724,719
1789	13,779,506
1790	14,921,084
1791	16,810,018
1792	18,336,851
1793	13,892,268
In 1794	£.16,725,402
1795	13,338,213
1796	19,102,220
1797	16,903,103
1798	19,672,503
1799	24,084,213
1800	24,304,283
1801	25,699,809
1802	26,993,129
1803	22,252,027
1804	23,935,793
1805	25,003,308

The real value of British produce and manufactures exported, however, considerably exceeds the above official statement, and as far as it can be ascertained, under the ad valorem duties, or computed at the average current prices of the goods, it amounted in the year 1804 to 40,349,642*l.* and in 1805 to 41,068,942*l.* The commodities included under the term British produce, such as alum, bark, coals, cattle, fish, hops, metals, salt, and a few other articles, being united in these accounts with manufactured goods, the actual value of the latter cannot be derived from them; but in a comparative view they furnish a sufficiently accurate idea of the proportions exported at different periods.

The annual produce of the different manufactures of this country, and the employment created by them, has in several instances been greatly over-rated; for if the number of persons which the various branches have at different times been represented to employ, were added together, they would make the population of the country far exceed its known amount, without any allowance whatever for other occupations.

The woollen-manufacture, which is the most antient and important, has increased during the last twenty years, and appears to be still increasing, notwithstanding the high price of the material, and the precarious state of the foreign markets. On a late examination of the principal woollen-manufacturers, by a committee of the house of commons, Mr. W. Hustler estimated the quantity of wool grown in this country at 600,000 packs, of 240 pounds each, which at 11*l.* per pack makes the value of the whole 6,600,000*l.* He justly observed that it is difficult to ascertain how much the wool is increased in value by being manufactured; some sorts are increased rather more than double, some nine times or even more; but if the average is taken at only three times, which will be under the truth, the total value of the wool manufactured in the country will amount to 19,800,000*l.* It must be remarked, that this calculation is founded on a supposition that, in 1791, the number of sheep in the kingdom was 28,800,000, which, as far as any idea can be formed from the proportion of the consumption of the metropolis to that of the whole island, and the stock requisite for the supply, greatly exceeded the truth at that time; and it is the general opinion, particularly of persons in the wool-trade, that of late the number of sheep kept has been considerably reduced. The calculation is likewise made at an unusually high price of wool; for though during the year 1800, the average price was about eleven guineas, the average of the three or four preceding years was certainly not more than from ten pounds to ten guineas; upon the whole, the estimate, therefore, will be much less objectionable, if formed on 500,000 packs at 10*l.* 10*s.* per pack, which will make the value of the wool 5,250,000*l.*; to this must be added at least 500,000*l.* for the value of Spanish wool imported, and the manufactured value of the whole will be 17,250,000*l.* That the total value of the manufacture cannot exceed this sum will appear highly probable from the exports. The value of woollen goods exported from Great Britain in six years, was as follows:

In 1794	£.4,390,920
1795	5,172,884
1796	6,011,133
1797	4,936,355
1798	6,499,339
1799	6,876,939

The average is 5,647,928*l.* Most of the custom-house values of goods exported are greatly below their present value, but not so much so in this article as in some others; they are found, however, to be about thirty-eight per cent. below the actual value, and this addition being made to the average amount, the value of woollen goods exported will appear to be 7,794,140*l.* The value retained for home consumption may be nearly equal to the value exported, although in quantity the former may greatly exceed the latter, a very considerable proportion of which consists of superfine and second cloths, whereas the consumption of fine woollens in Great Britain has much diminished of late years, from the general use of Manchester manufactures of cotton in clothing, particularly for waistcoats and breeches. The whole value of the manufacture thus appears to be about 15,588,000*l.* and, as a medium between this sum and the amount before stated, it may be taken at 16,400,000*l.* Deducting from this amount at the rate of 10 per cent. on the cost of the goods for the profits of the manufacturer, including the interest of his capital, there remains 14,909,090*l.* consisting of the cost of the material, and the wages of labour; the value of all the wool employed, we have seen, is about 5,750,000*l.* and including the cost of some other necessary articles, the materials cannot be valued at less than this sum; the remainder therefore, or 9,159,090*l.* is the amount of workmanship, or the wages of all the persons employed in the manufacture. It is scarcely possible to assume with precision an average rate of wages, with respect to any manufacture, as they vary in different parts of the country, and the proportion of the different classes of persons employed is in no instance known with certainty. In the West, where the woollen-manufacture has been for some time past in a very depressed state, few workmen get above 14*s.* per week, and many much less from not being fully employed; in Yorkshire good workmen earn from 16*s.* to 18*s.* per week, children 3*s.* older children and women from 5*s.* to 6*s.* and old men from 9*s.* to 12*s.* If, on taking all classes together, 8*s.* per week is not thought too high, it will appear that the whole number of persons employed does not exceed 440,340.

The value of the leather-manufacture was, some years ago, stated at 10,500,000*l.* and from the state of the trade of late, particularly those branches of it which supply military accoutrements, harness, sadlery, carriages, &c. combined with the high price of skins of most kinds, it cannot be supposed less than that sum at present. Deducting 954,545*l.* for the profits of capital employed, and 3,500,000*l.* for the cost of the raw article, there remains 6,045,455*l.* for the wages of persons employed therein, which, at 25*l.* per annum for each person, makes the number employed 241,818.

The cotton-manufacture was formerly of little importance in this country, in comparison with its present state. The total quantity of cotton-wool imported into England, on an average of five years, ending with 1705, was 1,170,881 pounds, and even so late as the year 1781, it amounted to only 5,101,920 pounds. About that time, however, the British calicoes, which had been introduced some years before, had arrived at some degree of perfection, and the branch of muslins being added, in which great improvements were soon after made, the whole manufacture experienced such a rapid and great increase, that previous to the commencement of the war with France, the consumption of cotton-wool amounted to upwards of 30,000,000 pounds per annum. In the years 1793, 1794, and 1795, the import was considerably less, but during the succeeding five years was as follows:

In 1796	31,280,000 lb.
1797	23,175,000
1798	31,592,000
1799	35,689,000
1800	56,010,000

The average is 35,549,200 pounds, the value of which, when manufactured, cannot be less than 11,000,000*l.* allowing for a considerable quantity exported in a partially manufactured state. The total quantity of British calicoes and muslins printed in England and Wales in the year 1800 was 28,692,790 yards, and in Scotland 4,176,939 yards, the duty on the whole amounting to 479,350*l.* 4*s.* 3½*d.* Upon the supposition that the duty is one-tenth of the value, the value of this description of goods printed in 1800, will be 4,793,502*l.* The quantity of white calicoes and muslins made in Great Britain, is probably much greater than that of the printed; and though they do not incur the expence of printing and duty, yet as a greater proportion of them are fine goods, the value of them is probably rather above 3,500,000*l.* There are many other branches of manufacture which consume large quantities of cotton, though it is difficult to form an idea of the precise amount; thus the hosiery branch was stated some years ago to employ 1,500,000 pounds, and it has certainly since increased considerably; the same quantity was said to be required for candle-wicks, and it will probably be a very moderate estimate to value all the cotton that is manufactured in any other way than in muslins and calicoes at 2,800,000*l.* The total value of the manufacture will thus appear to be, as before stated, about 11,000,000*l.* Deducting from this sum 1,000,000*l.* for profits of capital at ten per cent. and 4,443,650*l.* for cost of the raw material at 2*s.* 6*d.* per pound, there remains 5,556,350*l.* for wages, which, if divided at the rate of only 16*l.* per annum for each person, on account of the large proportion of women and children employed, makes the whole number 347,271 persons.

The silk-manufacture was formerly of greater extent than at present, but has not experienced any very considerable fluctuation for some years past: the quantity of raw and thrown silk imported in three years preceding the 5th January 1797, was as follows:

In 1794	906,686 lb.
1795	985,659
1796	758,970

The average of these three years is 883,438 pounds; and though the quantity in 1797 was still less than in 1796, the importation has since been greater, and the usual quantity cannot be stated at less than 900,000 pounds, the value of which when manufactured is about 2,700,000*l.* The cost of the silk to the manufacturer, if raw and thrown are taken together at only 28*s.* per pound, amounts to 1,260,000*l.* and the profits of the manufacturer 245,454*l.* at the rate of ten per cent. on the cost when manufactured. It may be said that though this is the usual profit charged by the manufacturer in this and some other branches, in casting up the selling price of his goods, they are frequently sold much under this price; which must be admitted: but, as an advantage is taken on most of the component parts of the price before the ten per cent. is laid on, it is probably not less than this rate on the whole, in this and in most other manufactures. The number of persons employed in the silk-manufactory has been stated at 200,000 and upwards, but there appears no reason to believe that it exceeds 65,000 of all descriptions.

The linen-manufacture of Great Britain is chiefly confined to Scotland, though some branches of it are carried on in Manchester and other parts of England. The exportation of British-made linen duty-free, was allowed in 1717, but the bounties on exportation were not granted till 1743, in which year the export was 52,772 yards. On an average of seven years of peace from 1749 to 1755, the export of British-manufactured linens had increased to 576,373 yards; and it continued to increase greatly during the succeeding period of war, the average of seven years, ending with 1762, being 1,356,640 yards. The average of the next seven years was 2,423,378 yards; but in consequence of the commercial embarrassments of the year 1773, this manufacture declined very much, and in the beginning of 1774, it is said there were not much more than half the weavers employed throughout Scotland and the north of England. In the course of a few years it revived again, and in the year 1783 the export amounted to no less than 14,298,000 yards. The total quantity of British linen exported during three years ending with 1779, was as follows:

In 1797	14,533,000 yards.
1798	20,744,000
1799	21,204,000

The value, estimated at the current prices of linens exported, on an average of three years preceding 5th January 1799, was 1,278,734*l.*; therefore, if the quantity retained for home consumption is not greater than the export, the value of the whole must be upwards of 2,500,000*l.*; and it probably will not exceed the truth if the yearly value of the whole of this manufacture in Great Britain, with the thread, and other branches of the flax trade, is stated at 3,000,000*l.* That it is not of less extent, may be presumed from the following account of the quantities of ugh flax and linen-yarn imported on an verage of five years, ending the 5th of January in the years stated, viz.

	Flax.	Linen-yarn.
1776	254,141 cwt.	7,847,157 lbs.
1787	245,636	8,873,866
1792	232,564	9,781,275
1799	290,754	8,148,936

The returns of the quantity and value of nen-cloth stamped for sale in Scotland, furish much information respecting the state of his manufacture; and were in three years nding with 1800, as follows:

	Yards.	Value.		
1 1798	21,297,059	£. 850,903	9	9
1799	24,506,007	1,116,022	4	7
1800	24,235,633	1,047,598	10	10

The linens which most of the families in cotland make for their own use, are not tamped, and consequently are not included n these returns, which must therefore be less han the quantity actually manufactured by everal millions of yards; and the value stated s certainly much below the actual selling rices. There is no account kept of the linenmanufacture in England; and as it is considered as an object of subordinate importance, ts annual value is probably under 1,000,000*l*. ut even if it is somewhat less than this mount, it will appear that the total value of he manufacture, rated at the current prices, annot be less than the sum before stated, or ,000,000*l*. The number of persons employed in it is probably not less than 95,000.

The hemp-manufacture at present exceeds ,600,000*l*. per annum, but is less in time of peace; the persons employed in it are probably about 35,000.

The paper-manufacture has been greatly advanced of late. A hundred years ago scarcely any paper was made in this country but the coarse wrapping papers; and for a ong time most of the superior kinds continued to be imported; the export is, however, at present considerable. The annual value of the manufacture, at the present high prices of the article, cannot be less than 900,000*l*. and the number of persons employed in it 30,000.

The glass-manufacture was much improved in the course of the last century, particularly in the article of plate-glass, and it has greatly increased of late years; it may now amount to 1,500,000*l*. per annum, and the persons employed in it to about 36,000.

The potteries, and manufactures of earthenware and porcelain, advanced rapidly during the last century in consequence of the great improvements made in them, and the introduction of many new and beautiful wares both for our own use and foreign markets. The article of queen's-ware was invented in 1763, by Mr. J. Wedgewood, to whom the public are also indebted for most of those elegant species of earthenware and porcelain which, moulded into a thousand different forms for ornament or use, now constitute the most valuable part of this manufacture. The annual value will probably not be overrated at 2,000,000*l*. and the number of persons employed at 45,000.

The iron-manufacture is supplied partly by the produce of our own mines, and partly by those of other countries; with respect to the first, it appears, that the total produce of pig-iron in Britain, is at least 100,000 tons; and reckoning on an average, that 33 cwt. of crude iron produce one ton of bars, and that the manufacture of malleable iron amounts to 35,000 tons per annum, this branch will require 57,750 tons of crude iron; and the value in bars at 20*l*. a ton, which is considerably under the present price, is 700,000*l*. the remaining 42,250 tons, cast into cannon, cylinders, and machinery, &c. at 14*l*. a ton, are worth 591,500*l*. The supply of foreign bar-iron is chiefly obtained from Russia and Sweden; and the quantity imported on an average of six years, ending with 1805, after deducting what was re-exported, has been 33,628 tons, value 865,182*l*. which with the sums before mentioned, amounts to 2,156,682*l*. This value is greatly increased by subsequent labour; but the proportion of the increase cannot be easily determined, the quantity of labour being so very different in different articles.

Some years ago the value of the iron-manufacture was estimated at 8,700,000*l*. which sum appears rather too high at present; but including tin and lead, the value of the whole will probably not be taken too high at 10,000,000*l*. and the number of persons employed at 200,000.

The copper and brass manufactures are now established in this country in all their branches. Till about the years 1720 or 1730, most of the copper and brass utensils for culinary and other purposes, used in this country, were imported from Hamburgh and Holland, being procured from the manufactories of Germany; even so late as the years 1745 and 1750, copper tea-kettles, saucepans, and pots of all sizes, were imported here in large quantities; but through the persevering industry, capitals, and enterprising spirit of our miners and manufacturers, these imports have become totally unnecessary, the articles being now all made here, and far better than any other country can produce. The discovery of new copper-mines in Cornwall, Derbyshire, and Wales, about the year 1773, contributed to the extension of the manufacture in this country; and it appears to be still increasing, notwithstanding the very great advance in the price of copper, which must certainly be attended with some disadvantage with respect to foreign markets. The value of wrought copper and brass exported during the year 1799 was 1,222,187*l*. and there is reason to believe, that the whole value of these manufactures at present is at least 3,600,000*l*. and the number of persons employed about 60,000.

The steel, plating, and hardware manufactures, including the toy trade, have been carried to a great extent of late years, and may amount in value to 4,000,000*l*. and the persons employed to at least 70,000.

It must be confessed, that many of these estimates are unavoidably defective from the want of public documents respecting many important branches of trade; they may, however, be sufficiently accurate to shew, in a general view, the relative extent of the principal manufactures of Great Britain, viz.

	Annual value.	Persons employed.
Woollen	£.16,400,000	440,340
Leather	10,500,000	241,818
Cotton	11,000,000	347,271
Silk	2,700,000	65,000
Linen and flax	2,000,000	95,000
Hemp	1,600,000	35,000
Paper	900,000	30,000
Glass	1,500,000	36,000
Potteries	2,000,000	45,000
Iron, tin, and lead	10,000,000	200,000
Copper and brass	3,600,000	60,000
Steel, plating, &c.	4,000,000	70,000
	£.67,200,000	1,665,429

There are many other manufactures, such as those of hats, horn, straw, &c. which, though of themselves of less importance than most of those above enumerated, are together of very considerable amount, and employ a great number of hands. There are likewise some, which, though not generally included among the manufactures, are certainly such in a great degree, and might, with much propriety, be classed with them.

It may be proper to observe, that those who have rated the number of persons employed in the different branches very considerably higher than is here stated, have generally included a variety of collateral employments, as mariners, carriers, miners, &c. whereas the numbers here given are meant to include only the persons directly employed in the various transactions and operations necessary for bringing the raw materials into their finished consumable state.

Trade-winds. See Wind.

TRADESCANTIA, a genus of the hexandria monogynia class of plants, the flower of which consists of three orbiculated, plane, and very patent petals; and its fruit is an oval trilocular capsule, containing a few angulated seeds. 19 species.

TRAGACANTH. See Astragalus.

Tragacanth, *gum*, or, as some call it, gum-adragant, or gum dragon, is the produce of the above and some other shrubs. The gum is brought to us in long and slender pieces, of a flatted figure more or less, and these not straight, or rarely so; but commonly twisted and contorted various ways, so as to resemble worms. We sometimes meet with it like the other vegetable exsudations, in roundish drops, but these are much more rare. It is moderately heavy, of a firm consistence, and properly speaking, very tough rather than hard; and is extremely difficult to powder, unless first carefully dried, and the mortar and pestle kept dry. Its natural colour is a pale whitish, and in the cleanest pieces it is something transparent. It is often, however, met with tinged brownish, and of other colours, and more opake. It has no smell, and very little taste, but what it has is disagreeable. Taken into the mouth, it does not grow clammy, and stick to the teeth, as the gum arabic does, but melts into a kind of very soft mucilage. It dissolves in water but slowly, and communicates its mucilaginous quality to a great quantity of that fluid. It is by no means soluble in oily or spirituous liquors, nor is it inflammable. It is brought to us from the island of Crete, and from several parts of Asia. It is to be chosen in long twisted pieces, of a whitish colour, very clear, and free from all other colours; the brown, and particularly the black, are wholly to be rejected.

Tragacanth has the same virtues with gum arabic, but in a greater degree. It greatly inspissates and obtunds the acrimony of the humours, and is therefore found of service in inveterate coughs, and other disorders of the breast, arising from an acrid phlegm, and in stranguries, heat of urine, and all other complaints of that kind. It is usually given in the compound powder, called the species diatragacanthi frigidæ, rarely alone. It is also, by some, esteemed a very great external remedy for wounds, and in this sense made an ingredient in some sympathetic powders, with vitriol and other things. It is by some recommended alone, in form of a powder or strong mucilage, for cracks and chaps in the nipples of women: but it is found, by experience, to be a very troublesome application in those cases, and to do more harm than good, as it dries by the heat of the part, and draws the lips of the wound farther asunder than before. See GUMS.

TRAGEDY. See POETRY.

TRAGIA, a genus of the monoecia triandria class of plants, without any flower-petals; its fruit is a very large tricoccous capsule of a roundish figure, containing single and roundish seeds. There are 8 species.

TRAGOPOGON, *goat's-beard*, a genus of plants of the class syngenesia, and the order polygamia æqualis; and in the natural system ranging under the 49th order, compositæ. The receptacle is naked, the calyx simple, and the pappus plumose. There are 14 species; of which two are British, the pratensis and porifolius. 1. The pratensis, or yellow goats'-beard, has its calyxes equal with the florets, and its leaves entire, long, narrow, sessile, and grassy. In fair weather this plant opens at sun-rising, and shuts between nine and ten in the morning. The roots are conical and esculent, and are sometimes boiled and served up at table like asparagus. It grows on meadows. 2. The porifolius, or purple goat's-beard, has the calyx longer than the radius of the floret; the flowers are large, purple, single, and terminal; and the leaves long, pointed, and bluish. The root is long, thick, and esculent. It grows in meadows, and is cultivated in gardens under the name of salsafy.

TRAJECTORY, a term often used, generally for the path of any body moving either in a void, or in a medium that resists its motion; or even for any curve passing through a given number of points. Thus Newton, Princip. lib. 1. prob. 22, purposes to describe a trajectory that shall pass through five given points.

TRAJECTORY *of a comet*, is its path or orbit, or the line it describes in its motion. This path, Hevelius, in his Cometographia, will have to be very nearly a right line; but Dr. Halley concludes it to be, as it really is, a very eccentric ellipsis; though its place may often be well computed on the supposition of its being a parabola. Newton, in prop. 41 of his 3d book, shews how to determine the trajectory of a comet from three observations; and in his last prop. how to correct a trajectory graphically described.

TRAMMELS, in mechanics, an instrument used by artificers for drawing ovals upon boards, &c. One part of it consists of a cross with two grooves at right angles; the other is a beam carrying two pins which slide in those grooves, and also the describing pencil. All the engines for turning ovals are constructed on the same principles with the trammels: the only difference is, that in the trammels the board is at rest, and the pencil moves upon it; in the turning engine, the tool, which supplies the place of the pencil, is at rest, and the board moves against it. See a demonstration of the chief properties of these instruments by Mr. Ludlam, in the Philos. Trans. vol. 70, p. 378, &c.

TRAMMEL-NET, is a long net, wherewith to take fowl by night in champain countries, much like the net used for the low bell, both in shape, bigness, and mashes. To use it, they spread it on the ground, so that the nether or further end, fitted with small plummets, may lie loose thereon; then the other part being borne up by men placed at the fore ends, it is thus trailed along the ground. At each side are carried great blazing lights, by which the birds are raised, and as they rise under the net they are taken.

TRANSCENDENTAL, or TRANSCENDANT, something elevated or raised above other things, which passes and transcends the nature of other inferior things.

Transcendental quantities, among geometricians, are indeterminate ones, or such as cannot be fixed, or expressed by any constant equation; such are all transcendental curves which cannot be defined by any algebraic equation, or which when expressed by an equation, one of the terms thereof is a variable quantity. Now whereas algebraists use to assume some general letters or numbers, for the quantity sought in these transcendental problems, Mr. Leibnitz assumes general or indefinite equations for the lines sought; *e.gr.* putting x and y for the absciss and ordinate, the equation he uses for a line sought is $a+bx+cy+exy+fxx+gyy$, &c.$=0$, by the help of which indefinite equation, he seeks the tangent: and by comparing the result with the given property of tangents, he finds the value of the assumed letters, a, b, c, d, &c. and thus defines the equation of the line sought.

If the comparison above-mentioned does not proceed, he pronounces the line sought not to be an algebraical, but a transcendental one. This supposed, he goes on to find the species of transcendency; for some transcendentals depend on the general division or section of a ratio, or upon the logarithms; others, upon the arcs of a circle; and others, on more indefinite and compound enquiries. He therefore, besides the symbols x and y, assumes a third, as v, which denotes the transcendental quantity; and of these three forms, a general equation for the line sought, from which he finds the tangent, according to the differential method, which succeeds even in transcendental quantities. The result he compares with the given properties of the tangent, and so discovers, not only the value of a, b, c, d, &c. but also the particular nature of the transcendental quantity. And though it may sometimes happen, that the several transcendentals are so to be made use of, and those of different natures too, one from one another; also though there are transcendents of transcendentals, and a progression of these in infinitum; yet we may be satisfied with the most easy and useful one; and for the most part, may have recourse to some peculiar artifices for shortening the calculus, and reducing the problem to as simple terms as may be.

This method being applied to the business of quadratures, or to the invention of quadratics, in which the property of the tangent is always given, it is manifest, not only how it may be discovered, whether the indefinite quadrature may be algebraically impossible; but also, how, when this impossibility is discovered, a transcendental quadratrix may be found, which is a thing not before shewn. So that it seems that geometry, by this method, is carried infinitely beyond the bounds to which Vieta and Des Cartes brought it; since, by this means, a certain and general analysis is established, which extends to all problems of no certain degree, and consequently not comprehended within algebraical equations.

Again, in order to manage transcendental problems, wherever the business of tangents or quadratures occurs, by a calculus, there is hardly any that can be imagined shorter, more advantageous, or more universal, than the differential calculus, or analysis of indivisibles and infinites.

By this method, we may explain the nature of transcendental lines, by an equation; *e. gr.* Let a be the arch of a circle, and x the versed sine; then will $a = \frac{sdx}{\sqrt{2x - xx}}$; and, if the ordinate of the cycloid is y, then will $y = \sqrt{2x - xx} + \frac{sdx}{\sqrt{2x - xx}}$; which equation perfectly expresses the relation between the ordinate y and the absciss x, and from it all the properties of the cycloid may be demonstrated.

Thus is the analytical calculus extended to those lines, which have hitherto been excluded; for no other reason, but that they were thought incapable of it.

TRANSFORMATION *of Equations*, in algebra, is the changing equations into others of a different form, but of equal value. This operation is often necessary, to prepare equations for a more easy solution, some of the principal cases of which are as follow: 1. The signs of the roots of an equation are changed, viz. the positive roots into negative, and the negative roots into positive ones, by only changing the signs of the 2d, 4th, and all the other even terms of the equation. Thus the roots of the equation

$$x^4 - x^3 - 19x^2 + 49x - 30 = 0, \text{ are}$$
$$+1, +2, +3, -5;$$

whereas the roots of the same equation having only the signs of the 2d and 4th terms changed, viz. of $x^4 + x^3 - 19x^2 - 49x - 30 = 0$, are $-1, -2, -3, +5$.

2. To transform an equation into another that shall have its roots greater or less than the roots of the proposed equation by some given difference, proceed as follows: Let the proposed equation be the cubic $x^3 - ax^2 + bx - c = 0$; and let it be required to transform it into another, whose roots shall be less than the roots of this equation by some given difference d; if the root y of the new equation must be the less, take it $y = x - d$, and hence $x = y + d$; then, instead of x and its powers, substitute $y + d$ and its powers, and there will arise this new equation

$$\text{(A)} \quad \left.\begin{array}{l} y^3 + 3dy^2 + 3d^2y + d^3 \\ \quad\; - ay^2 - 2ady - ad^2 \\ \qquad\qquad\; + by + bd \\ \qquad\qquad\qquad\; - c \end{array}\right\} = 0;$$

whose roots are less than the roots of the former equation by the difference d. If the roots of the new equation had been required to be greater than those of the old one, we must then have substituted $y = x + d$, or $x = y - d$, &c.

3. To take away the 2d or any other particular term out of an equation; or to transform an

equation, so that the new equation may want its 2d, or 3d, or 4th, &c. term of the given equation $x^3 - ax^2 + bx - c = 0$, which is transformed into the equation (A) in the last article. Now to make any term of this equation (A) vanish, is only to make the co-efficient of that term $= 0$; which will form an equation that will give the value of the assumed quantity d, so as to produce the desired effect, viz. to make that term vanish. So, to take away the 2d term, make $3d - a = 0$, which makes the assumed quantity $d = \frac{1}{3}a$. To take away the 3d term, we must put the sum of the co-efficients of that term $= 0$, that is, $3d^2 - 2ad + b = 0$, or $3d^2 - 2ad = -b$; then, by resolving this quadratic equation, there is found the assumed quantity $d = \frac{1}{3}a \pm \frac{1}{3}\sqrt{a^2 - 3b}$, by the substitution of which for d, the 3d term will be taken away out of the equation.

From whence it appears that, to take away the 2d term of an equation, we must resolve a simple equation; for the 3d term, a quadratic equation; for the 4th term, a cubic equation, and so on.

4. To multiply or divide the roots of an equation by any quantity; or to transform a given equation to another, that shall have its roots equal to any multiple or submultiple of those of the proposed equation. This is done by substituting, for x and its powers, $\frac{y}{m}$, or py, and their powers, viz. $\frac{y}{m}$ for x, to multiply the roots by m; and py for x, to divide the roots by p.

Thus, to multiply the roots by m, substituting $\frac{y}{m}$ for x in the proposed equation,

$x^n - ax^{n-1} + bx^{n-2}$ &c $= 0$, and it becomes

$$\frac{y^n}{m^n} - \frac{ay^{n-1}}{m^{n-1}} + \frac{by^{n-2}}{m^{n-2}} \text{ \&c} = 0;$$

or multiply all by m^n, then is

$$y^n - amy^{n-1} + bm^2y^{n-2} - cmcy^{n-3} \text{ \&c} = 0,$$

an equation that has its roots equal to m times the roots of the proposed equation.

In like manner, substituting py for x, in the proposed equation, &c. it becomes

$$y^n - \frac{ay^{n-1}}{p} + \frac{by^{n-2}}{p^2} - \frac{cy^{n-3}}{p^3} \text{ \&c} = 0,$$

an equation that has its roots equal to those of the proposed equation divided by p.

From whence it appears, that to multiply the roots of an equation by any quantity m, we must multiply its terms, beginning at the 2d term, respectively by the terms of the geometrical series, m, m^2, m^3, m^4, &c. And to divide the roots of an equation by any quantity p, that we must divide its terms, beginning at the 2d, by the corresponding terms of this series p, p^2, p^3, p^4, &c.

5. And sometimes, by these transformations, equations are cleared of fractions, or even of surds. Thus the equation

$$x^3 - ax^2\sqrt{p} + bx - c\sqrt{p} = 0,$$

by putting $y = x\sqrt{p}$, or multiplying the terms, from the 2d, by the geometricals $\sqrt{p}$, p, $p\sqrt{p}$, is transformed to

$$y^3 - apy^2 + bpy - cp^2 = 0.$$

6. An equation, as $x^3 - ax^2 + bx - c = 0$, may be transformed into another, whose roots shall be the reciprocals of the roots of the given equation, by substituting $\frac{1}{y}$ for x; by which it becomes $\frac{1}{y^3} - \frac{a}{y^2} + \frac{b}{y} - c = 0$; or, multiplying all by y^3, the same becomes

$$cy^3 - by^3 + ay - 1 = 0.$$

TRANSIT, in astronomy, signifies the passage of any planet, just by or over a fixed star, or the sun; and of the moon in particular, covering or moving over any planet.

TRANSIT INSTRUMENT. See OBSERVATORY.

TRANSITION, in music, the softening a disjunct interval by the introduction of intermediate sounds. In harmony, transition is the changing the genus, or mode, in a sensible but regular manner. Thus, when in the diatonic genus the bass moves so as to require in the parts the introduction of a minor semitone, it is a chromatic transition; and if we change the tone by favour of a diminished seventh, it is an enharmonic transition.

TRANSMISSION. See OPTICS.

TRANSMUTATION, in geometry, denotes the reduction or change of one figure or body into another of the same area or solidity, but of a different form; as a triangle into a square, a pyramid into a parellelopiped, &c. In the higher geometry, transmutation is used for the converting a figure into another of the same kind and order, whose respective parts rise to the same dimensions in an equation, admit of the same tangents, &c. If a rectilinear figure is to be transmuted into another, it is sufficient that the intersections of the lines which compose it are transferred, and the lines drawn through the same in the new figure. If the figure to be transmuted is curvilinear, the points, tangents, and other right lines by means whereof the curve line is to be defined, must be transferred.

TRANSOM, among builders, denotes the piece that is framed across a double-light window.

TRANSOM, among mathematicians, signifies the vane of a cross-staff, or a wooden number fixed across, with a square whereon it slides, &c.

TRANSOM, in a ship, a piece of timber which lies athwart the stern, between the two fashion-pieces, directly under the gun-room port.

TRANSPORTATION, the act of conveying or carrying a thing from one place to another.

Transportation is a kind of punishment, or more properly an alleviation or commutation of punishment, for criminals convicted of felony; who for the first offence, unless it is an extraordinary one, are generally transported to the plantations (at present to New South Wales), there to bear hard labour for a term of years; within which if they return, they are executed without further trial than identifying their persons.

TRANSPORTATION *of plants*. In sending plants from one country to another, great cautions are necessary. The plants sent from a hotter country to a colder, should be always put on board in the spring of the year, that the heat of the season may be advancing as they approach the colder climates; and, on the contrary, those which are sent from a colder country to a hotter, should be sent in the beginning of winter. The best way of packing up plants for a voyage, if they are such as will not bear keeping out of the earth, is to have boxes with handles, filling them with earth, and planting the roots as close together as may be; the plants should be set in these boxes three weeks before they are to be put on board; and in good weather they should be set upon the deck, and in bad removed or covered with a tarpaulin. If they are going from a hotter country to a colder one, they must have very little moisture; if, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being shaded from the heat of the sun, they will come safe.

A great many plants, however, will live out of the earth a considerable while; as the sedums, euphorbiums, mesembryanthemums, and other succulent ones. These need no other care than the packing them up with moss in a close box; and there should be a little hay put between them, to prevent them from wounding or bruising one another, and holes bored in the boxes to keep them from heating and putrefying. In this manner they will come safe from a voyage of two or three, or even four or five months. Several trees also will come safe in the same manner; taking them up at a season when they have done growing, and packing them up with moss. Of this sort are oranges, olives, capers, jasmines, and pomegranate-trees. These, and many others, are annually brought over to us from Italy; and, though they are three or four months in the passage, seldom miscarry. The best way of sending over seeds, is in their natural husks, in a bag, or packed up in a gourd-shell, keeping them dry, and out of the way of vermin.

TRANSPOSITION, in algebra, the bringing any term of an equation over to the other side.

TRANSUBSTANTIATION, in theology, the conversion or change of the substance of the bread and wine in the eucharist, into the body and blood of Jesus Christ, which the Romish church hold is wrought by the consecration of the priest. This is a main point in the Romish religion, and is rejected by the protestants, the former maintaining the transubstantiation to be real, the latter only figurative; interpreting the text hoc est corpus meum, "this *signifies* my "body:" but the council of Trent stood up strenuously for the literal sense of the verb *est*, and say expressly, that in transubstantiation the body and blood of our Lord Jesus Christ are truly, really, and substantially, under the species of bread and wine. The controversies about this point are almost innumerable.

TRANSVERSE MUSCLES, in anatomy, are certain muscles arising from the transverse processes of the vertebræ of the loins. See ANATOMY.

TRAPA, a genus of the tetrandria monogynia class of plants, the corolla whereof consists of four petals, vertically ovated, and larger than the cup: the fruit is a hard osseous capsule, of an oblong oval figure, containing only one cell, and armed with four sharp thick spines, placed oppositely in the middle of the sides, and pointed; these before were the leaves of the calyx: the seed is a covered single nucleus, of an oval figure. There are two species, aquatics.

TRAPEZIUM, in geometry, a plane figure contained under four unequal right lines. 1. Any three sides of a trapezium taken together, are greater than the third. 2. The two diagonals of any trapezium, divide it into four proportional triangles. 3. If two sides of a trapezium are parallel, the rectangle under the aggregate of the parallel sides and one-half their distance, is equal to that trapezium. 4. If a parallelogram circumscribes a trapezium, so that one of the sides of the parallelogram is parallel to a diagonal of the trapezium, that parallelogram will be the double of the trapezium. 5. If any trapezium has two of its opposite angles, each a right angle, and a diagonal is drawn joining these angles; and if from the other two angles are drawn two perpendiculars to that diagonal; the distances from the feet of these perpendiculars to those right angles, respectively taken, will be equal. 6. If the sides of a trapezium are each bisected, and the points of bisection are joined by four right lines, these lines will form a parallelogram, which will be one-half of the trapezium. 7. If the diagonals of a trapezium are bisected, and a right line joins these points, the aggregate of the squares of the sides is equal to the aggregate of the squares of the diagonals, together with four times of the square of the right line joining the point of bissection. 8. In any trapezium, the aggregate of the diagonals is less than the aggregate of four right lines drawn from any point (except the intersection of the diagonals) within the figure.

TRAPS. See Rocks, *primitive.*

TRAVERSE, or Transverse, in general, denotes something that goes athwart another; that is, crosses and cuts it obliquely.

Hence, to traverse a piece of ordnance, among gunners, signifies to turn or point it which way one pleases, upon the platform.

In fortification, traverse denotes a trench with a little parapet, or bank of earth, thrown perpendicularly across the moat, or other work, to prevent the enemy's cannon from raking it. These traverses may be from twelve to eighteen feet, in order to be cannon-proof; and their height about six or seven feet, or more if the place is exposed to any eminence. And to preserve a communication, a passage of about five or six feet wide must be left at one end of the traverse. If any part of a work, thus shut in by one or more traverses, is likely to be defended by the musketry, it will be proper to add to the traverses one or more footbanks within the defence, for the troops to mount on when they want to fire over the traverse.

Traverse. See Navigation.

Traverse, in law, signifies sometimes to deny, sometimes to overthrow or undo a thing, or to put one to prove some matter; much used in answers to bills in chancery: or it is that which the defendant pleads or says in bar to avoid the plaintiff's bill, either by confessing and avoiding, or by denying and traversing the material parts thereof.

Traverse an Indictment, is to take issue upon the chief matter, and to contradict or deny some point of it. A traverse must be always made to the substantial part of the title. Where an act may indifferently be intended to be at one day or another, there the day is not traversable. In an action of trespass generally, the day is not material; though if a matter is done upon a particular day, there it is material and traversable. 2 Roll's Rep. 37.

TRAVESTY, or Travesti, a French term, derived from the verb travestir, to disguise one's self, or to appear in masquerade: and hence, travesty is applied to the disfiguring of an author, or the translating him into a style and manner different from his own, by which means it becomes difficult to know him.

TREACLE. See Sugar, &c.

TREASON, in law, is divided into high treason and petty treason. High treason, as comprized under the famous high treason act, as it is called, or the statute 25th Edw. III., is divided into seven heads.

1. When a man compasses or imagines the death of the king, queen, or the heir apparent, he is guilty of high treason. But as this compassing or imagining is an act of the mind, it cannot be proved unless demonstrated by some overt (or open) act. To conspire to imprison the king, and to assemble company for the purpose, to procure arms and ammunition with the intent to kill him, or even taking any measures to put such designs into execution, as consulting of the best means of putting him to death, are overt or open acts.

2. To violate the queen-consort, the king's eldest daughter, or the wife of the heir apparent, is high treason; and if both parties consent, they are alike guilty. This is to guard the blood royal from pollution, so that to violate a queen or princess dowager is not treason.

3. If a man levies war against the king in his realm, he is guilty of high treason. This may be done under pretence of redressing grievances, as well as to dethrone the king. An insurrection with the avowed design of destroying all inclosures, all brothels, &c. is likewise treason; though a tumult to destroy any particular inclosure or brothel would only amount to a riot: but in the first instance, the universality of the design renders it high treason. A mere conspiracy to level war is not treason, unless the design is particularly pointed against the king, when it falls under the first head, viz. compassing or imagining his death.

4. To be an adherent to the king's enemies in his realm, or aiding them in his realm, or elsewhere, is treason; but this must be demonstrated by some overt act, as the giving them intelligence, sending provisions, surrendering up a fortress by combination with the enemy, and not by cowardice, in which case it is an offence against the laws of war, but not treason. Giving assistance to foreign pirates or robbers who invade our coasts without any open hostilities between their nation and our own, or any commission from any state at war with Great Britain; also aiding our own fellow-subjects in rebellion at home; are both treasons; but to relieve a rebel fled out of the kingdom is not. And if a person through force or fear is obliged to join the rebels, provided he leaves them at the first safe opportunity, he is not guilty.

5. Counterfeiting the great or privy seal is likewise high treason.

6. Counterfeiting the king's money; or bringing false and counterfeit money into the realm, and knowing it to be false, uttering it, is the sixth species of treason. Counterfeiting it is of itself treason, without making payment with it; and if the minters alter the legal standard of gold and silver, it is treason. As to importing foreign counterfeit money, it is held that uttering it without importing it is not within the statute.

7. The seventh and last species of treason under this statute is, if a man slays the chancellor, treasurer, or the king's justices of either of the benches, justices in eyre, or justices of assize, and all other justices assigned to hear and determine, being in their places during their offices. This extends only to killing them, and not to wounding and assaulting them. The barons of the exchequer are not specified as within the act, but by the stat. 5 Eliz. c. 18, and 1 W. and M. c. 21, the lord keeper or commissioners of the great seal are within it.

There are other treasons, not comprized under this act, which may be divided into three heads: 1. Such as relate to papists. 2. Such as relate to falsifying the coin or other royal signatures. 3. Such as relate to securing the protestant succession in the house of Hanover.

For the first see Papists. For the second see Coinage.

8. By the stat. 1 Anne, s. 2, c. 17, if any person shall endeavour to deprive or hinder any person being the next in succession to the crown, according to the limitations of the act of settlement, from succeeding to the crown, and attempt the same by any overt act, such offence shall be high treason. And by stat. 6 Anne, c. 7. if any person by writing or printing maintains and affirms that any person has any right or title to the crown of this realm, otherwise than according to the act of settlement; or that the kings of this realm, with the authority of parliament, are not able to make laws and statutes to bind the crown and the descent thereof; such person shall be guilty of high treason.

The punishment for this crime is very severe; that the criminal shall be dragged on the ground to the place of execution, though a sledge is now allowed through humanity, and be hanged and cut down alive, his entrails taken out and burned before his face, his head cut off, and his body quartered. The punishment for coining is, however, more mild.

Treason, *misprision of.* There is likewise a misprision of treason, which is the concealing the knowledge of treason without assenting to it, 1 and 2 Ph. and Mary, c. 10. The stat. 13 Eliz. c. 2, enacts, that those who forge foreign coins not current in Great Britain, their aiders, abettors, and procurers, shall be all guilty of misprision of treason. The punishment for this crime, which is a degree lower than high treason, is loss of the profits of lands for life, forfeiture of goods, and perpetual imprisonment.

Treason, *petit* (which is an aggravated degree of murder), according to the stat. 25th Edw. III. c. 2, may happen three ways; by a servant killing his master, a wife her husband, or an ecclesiastical person his superior to whom he owes faith and obedience: a servant who kills his master, whom he has left upon a grudge conceived while in his service; for the intention was formed while the relation subsisted: so if a wife is separated a mensa & thoro, the vinculum matrimonii is not dissolved; and if she kills her husband after the divorce, she is guilty. And a clergyman owes canonical obedience to the bishop who ordained him, to him in whose diocese he is beneficed, and also to the metropolitan of such suffragan; and therefore to kill any of these is petit treason. The punishment is, for a man, to be drawn and hanged; for a woman, it was to be drawn and burnt; but this barbarous act is now repealed, and the punishment made simil r to that of the men. They, their aidors and abettors, are deprived the benefit of clergy.

TREASURE TROVE, is where any money or coin, gold, silver, plate, or bullion, is hidden in the earth, or other private place, the owner being unknown; in which case, the treasure belongs to the king, or some other who claims by the king's grant, or by prescription. Brac. Lib. 3. But if he that hid it is known, or afterwards found out, the owner, and not the king, is entitled to it. 1 Black. 295. If it is found in the sea, or upon the earth, it does not belong to the king, but to the finder, if no owner appears. Black. 295.

TREASURER, an officer to whom the treasure of a prince, or corporation, is committed to be kept, and duly disposed of.

The lord high treasurer of Great Britain, or first commissioner of the treasury when in commission, has under his charge and government all the king's revenue, which is kept in the exchequer. He holds his place during the king's pleasure, being instituted by the delivery of a white staff to him: he has the check of all the officers employed in collecting the customs and other royal revenues; and in his gift and disposition are all the offices of the customs in the several ports of the kingdom; escheators in every county are nominated by him; he also makes leases of the lands belonging to the crown. This office is now always executed by a commission, who are entitled, "the commissioners for executing the office of lord high treasurer," and the first commissioner is commonly prime minister.

There is, besides the lord-treasurer, a treasurer of the king's houshold; who is of the privy council, and, with the comptroller and steward of the marshalsea, has great power.

To these may be added the treasurer of the navy; as also the treasurer of the king's chamber, and of the wardrobe; and most corporations throughout the kingdom have treasurers, whose office is to receive their rents, and disburse their common expences.

The treasurer of the county is an officer that keeps the county-stock, in which office there are two in every county; who are chosen by the major part of the justices of the peace at Easter-sessions. They ought to have certain estates in lands, or to be worth 150*l.* in personal estate; and are to continue in their office only for a year, at the end whereof, or within ten days after the expiration of the year, they must account to their successors, under certain penalties. The county-stock which this officer has the keeping of, is raised by rating every parish annually; and the same is from time to time disposed of to charitable uses, towards the relief of maimed soldiers and mariners, prisoners in the county gaols, paying the salaries of governors of houses of correction, and relieving poor alms-houses, &c.

TREE. See Forest Trees, Planting, Plants, Timber, &c.

TREFOIL. See Trifolium.

TREMELLA, a genus of plants of the class of cryptogamia, and natural order of algæ. It is a gelatinous membranous substance; the parts of the fructification scarcely visible. There are 11 species, of which five are indigenous; the nostoc, lichenoides, verrucosa, hemispherica, and purpurea. 1. The nostoc, or jelly rain tremella, is found in pastures and by the sides of gravel-walks in gardens after rains; not uncommon in spring, summer, and autumn. It is a membranaceous, pellucid, and gelatinous substance, without any visible root; of a yellowish dull green-colour; assuming various forms, either round, angular, plaited or folded together irregularly, like the intestines, or a pocket-handkerchief, an inch or two, or more, in diameter: soft to the touch when moist; but thin, membranaceous, and brittle, when dry; and of a black fuscous colour. The antient alchemists called this vegetable the flowers of heaven, and imagined that from it they should procure the universal menstruum: but all their researches ended in discovering that by distillation it yielded some phlegm, volatile salt, and empyreumatic oil. It has been extolled in wounds, ulcers, &c. but no regard is ever paid to it by judicious practitioners. Dr. Darwin says, he has been well informed that this tremella is a mucilage voided by herons after they have eaten frogs. 2. The lichenoides, or transparent tremella, is erect, plane, margin curled, lacinulated, and brown. It grows on heaths and in woods, &c. 3. Verrucosa, or warty tremella, is tubercular, solid, wrinkled, roundish, and resembling a bladder; it is of a blackish yellow. It grows on stones in rivulets. 4. Hemispherica, or sea tramella, is scattered among confervæ, fuci, &c. 5. Purpurea, or purple tremella, is globular, sessile, solitary, and smooth. It grows on ditch-banks about London.

TREMOLITE. This mineral is found chiefly near St. Gothard, in Switzerland; and takes its name from mount Tremola, where it was first observed by Saussure. It occurs massive and in crystals. The primitive form of its crystals is a rhomboidal prism, whose sides are inclined to each other at angles of 126° 52′ 12″ and 53° 7′ 48″. It usually occurs in four-sided prisms, terminated by dihedral summits; and not unfrequently the two acute edges, or all the four, are truncated. Texture radiated. Fragments splintery. Specific gravity from 2.9 to 3.2. Fibres easily separated, so that it appears soft, yet it scratches glass. Phosphoresces very readily when struck or rubbed in the dark. Before the blowpipe, melts into a white scoria. Werner divides this species into three subspecies.

A specimen of tremolite analysed by Klaproth, contained

65.0	silica
38.0	lime
0.5	magnesia
0.5	oxide of iron
6.0	water and carbonic acid.
100.0	

A specimen of this mineral from the castle-hill of Edinburgh, analysed by Dr. Kennedy, yielded

51.5	silica
32.0	lime
0.5	alumina
0.5	oxide of iron
8.5	soda
5.0	carbonic acid
98.0,	with some traces of magnesia and muriatic acid.

Bournon has shewn that the property which the tremolite has of phosphorescing when rubbed, is owing to the presence of carbonat of lime.

TREMOR. See Medicine.

TRENCHES, in a siege, are ditches made by the besiegers, that they may approach more securely to the place attacked; on which account they are also called lines of approach. The tail of the trench is the place where it was begun, and its head is the place where it ends.

Trenches are also made to guard an encampment.

The trenches are usually opened or begun in the night-time, sometimes within musket-shot, and sometimes within half or whole cannon-shot of the place; generally about 800 fathoms. They are carried on in winding lines, nearly parallel to the works, so as not to be in view of the enemy, nor exposed to the enemy's shot.

The workmen employed in the trenches are always supported by a number of troops to defend them against the sallies of the besieged. The pioneers, and other workmen sometimes work on their knees, and are usually covered with mantlets or saucissons; and the troops who support them lie flat on their faces, in order to avoid the enemy's shot. On the angles or sides of the trench, there are lodgments, or epaulements, in form of traverses, the better to hinder the sallies of the garrison, and to favour the advancement of the trenches, and to sustain the workmen.

The platforms for the batteries are made behind the trenches; the first at a good distance, to be used only against the sallies of the garriosn. As the aproaches advance, the batteries are brought nearer, to ruin the defences of the place, and dismount the artillery of the besieged. The breach-batteries are made when the trenches are advanced near the covert-way.

If there are two attacks, it will be necessary to have lines of communication, or boyaus, between the two, with places of arms at convenient distances. The trenches are 6 or 7 feet high with the parapet, which is 5 feet thick, with banquettes for the soldiers to mount upon.

The approaches at a siege are generally carried on upon the capitals of the works attacked; because the capitals produced are, of all other situations in the front of a work, the least exposed to the fire of either the cannon or musketry; and are the least in the line of fire between the besieged and besiegers' batteries. But if, from particular circumstances, these or other advantages do not attend the approaches upon the capitals, they are by no means to be preferred to other positions.

The trenches of communication, or zigzags, are 3 feet deep, 10 feet wide at bottom, and 13 feet at top, having a berm of one foot, beyond which the earth is thrown to form a parapet.

The parallels or places of arms of the trenches are 3 feet deep, 12 feet wide at bottom, and 17 or 18 feet wide at top, having a banquette of about 3 feet wide, with a slope of nearly as much.

The first night of opening the trenches, the greatest exertions are made to take advantage of the enemy's ignorance as to the side of attack; and they are generally carried on as far in advance as the first parallel, and even sometimes to the completion of that work. The workmen set out on this duty, each with a fascine of 6 feet, a pick-ax, and a shovel; and the fascines being laid so as to lap one foot over each other, leave 5 feet of trench for each man to dig.

The usual method of directing the trenches or zig-zags, is by observing during the day some near object in a line with the salient parts of the work, and which may serve as a direction in the night: or if the night is not very dark, the angles of the works may be seen above the horizon; but as both these methods are subject to uncertainty, the following is proposed to answer every case: having laid down the plan of attack, the exact positions of the flanked angles of the works of the front attacked, and particularly of those most extended to the right and left; mark on the plan the point of commencement for the first portions of zig-zag, the point where it crosses the capital, and the point to which it extends on the other side of the capital: this last point will be the commencement of the second branch: then mark off the point where this branch crosses the capital, and its extent on the other side; and this will give the commencement of the third branch; and so on for the others. Thus provided with a plan ready marked off, it will be very easy, even in the darkest night, to lay down the points where the zig-zags are to cross the capital, and the points to which they are to be produced beyond them. The first parallel is generally run about 600 yards from the place, and of such extent as to embrace the prolongation of the faces of all the works which fire upon the trenches; and each end has a return of about 30 or 40 yards.

The second parallel is constructed upon the same principles, and of the same extent, as the first, at the distance of about 300 yards from the salient angles of the covert-way. This parallel is usually formed of gabions; each workman carrying a gabion, a fascine, a shovel, and a pick ax. After this the trenches are usually carried on by sap.

The half-parallels are about 140 or 150 yards from the covert-way, and extend sufficiently on each side to embrace the prolongation of the branches of a covert-way.

The third parallel must not be nearer than the foot of the glacis, or it will mask the ricochet batteries. It is generally made rather wider than the other parallels.

Cavaliers of the trenches must not be nearer than 28 yards from the covert-way, or they will be liable to be annoyed by hand-grenades.

Trench, *returns of a*, are the elbows and turnings, which form the lines of approach, and are made, as near as can be, parallel to the place, to prevent their being enfiladed.

Trenches, *to mount the*, is to mount guard in the trenches, which is generally done in the night.

Trenches, *to relieve the*, is to relieve the guard of the trenches.

Trenches, *to scour the*, is to make a vigorous sally upon the guard of the trenches, force them to give way and quit their ground, drive away the workmen, break down the parapet, fill up the trench, and nail their cannon.

Trenches, *counter*, are trenches made against the besiegers; which consequently have their parapet turned against the enemy's approaches, and are enfiladed from several parts of the place, on purpose to render them useless to the enemy, if they should chance to become masters of them; but they should not be enfiladed or commanded by any height in the enemy's possession.

Trenches, *to open the*, is to break ground for the purpose of carrying on approaches towards a besieged place.

TREPANNING. See Surgery.

TREPIDATION. See Medicine.

TRESPASS, is any trangression of the law, under treason, felony, or misprision of either. Staundf. Pl. Cor. 38.

Trespass signifies going beyond what is lawful; hence it follows that every injurious act is, in the large sense of this word, a trespass. But as many injurious acts are distinguished by particular names, as treason, murder, rape, and other names, the legal sense of the word trespass is confined to such injurious acts as have not acquired a particular name. Some trespasses are not accompanied with any force; a trespass of this sort is called a trespass upon the case: and the proper remedy for the party injured, is by an action upon the case. Other trespasses are accompanied with force, either actual or implied. If a trespass which was accompanied with either actual or implied force, has been injurious to the public, the proper remedy in every such case, is by an indictment, or by information. And if a trespass that was acccompanied with an actual force, has been injurious only to one or more private persons, the offender is in every such case liable to an indictment, or to an information; for although the injury has in such case been only done to one or more private persons, as every trespass accompanied with actual force is a breach of the peace, it is to be considered and punished as an offence against the public. 5 Bac. Abr. 150.

A man is answerable for not only his own trespass, but that of his cattle also. 3 Black. 211.

And the law gives the party injured, a double remedy in this case; by permitting him to distrain the cattle thus doing damage, till the owner shall make him satisfaction, or else by leaving him to the common remedy by action. And in either of these cases of trespass committed on another's land, either by a man himself or his cattle, the action that lies, is the action of trespass with force and arms; for the law always couples the idea of force with that of intrusion upon the property of another. 3 Black. 210.

In some cases, trespass is justifiable; or rather entry on another's land or house shall not in these cases be accounted trespass: as if a man came there to demand or pay money there payable, or to execute in a legal manner the process of the law. 3 Black 219.

To prevent trifling and vexatious actions of trespass, it is enacted by 43 Eliz. c. 6. 22 and 23 Car. II. c. 9. and 8 & 9 W. c. II. that where a jury who try an action of trespass, give less damages than 40*s*. the plaintiff shall be allowed no more costs than damages; unless the judge shall certify on the back of the record, that the freehold or title of the land came chiefly in question. But if it shall appear that the trespass was wilful and malicious, the plaintiff shall have his full costs. And every trespass is wilful, where the defendant has been forewarned, and malicious where the intent of the defendant appears to be to harass or injure the plaintiff. 3 Black. 370.

TRESPASSER, denotes a person that commits a trespass against another; in respect of whom it is held, that though the law permits a person to enter a tavern, and a landlord to distrain on lands, &c. yet if he abuses this liberty by committing any trespass, he will be judged a trespasser ab initio.

TRET, in commerce, an allowance made for the waste, or the dirt, that may be mixed with any commodity, which is always four pounds in every hundred and four pounds weight. See Tare.

TREWIA, a genus of the polyandria monogynia class of plants, having no corolla besides the cup; the fruit is a turbinated, triquetrous, coronated, trilocular, trivalvar capsule: the seed is single, convex on one side, and angular on the other. There is one species, a tree of the East Indies.

TRIAL, in law, the examination of a cause, civil or criminal, according to the laws of the land, before a proper judge: or, it is the manner and order observed in the hearing and determining of causes. There are divers kinds of trials; as those of matters of fact, which must be tried by a jury; matters of law which are only triable by the courts; and matters of record, which are to be tried by the records themselves. The most general rule has been, that the jurymen on a trial shall be chosen out of that town or precinct, &c. in which the matter of fact is alleged, or the nearest thereto, for the better cognizance of the matter; and not to leave things to be tried in foreign counties, where the jury are strangers to the whole matter. Where any trial is for murder, it must be in the county wherein the fact was committed; but if the assault is in one county, and the person assaulted happens to die in another county, the indictment may be found by a jury of the county where the party died: and by special commission, when a person is indicted in one county he may be tried in another. In all criminal cases the custom is to ask the prisoner how he will be tried, which was formerly a very significant question, though it is not so now; because antiently there were trials by combat, by ordeal, and by jury; and when the prisoner answered, By God and his country, it appeared he made choice to be tried by a jury; which is the only way now used for the trial of criminals.

The method of proceeding in a criminal case is this: First the bill of indictment against the offender is prepared, and the prosecutor and his witnesses attend on the grand jury, and there give in their evidence; which being done, the grand inquest either find the bill of indictment, or bring it in ignoramus; and if the bill is found, the prisoner is brought to the bar of the court, and the clerk of the arraigns calling him by his name, desires him to hold up his hand, saying, "Thou art indicted by the name of — —, for such a felony, &c. (setting forth the crime laid in the indictment). How sayest thou; art thou guilty of this felony whereof thou art indicted, or not guilty?" To which the prisoner answering, "Not guilty," the clerk says, "Culprit, how wilt thou be tried?" whereupon the defendant answers, "By God and my country;" which plea of the prisoner the clerk records, and then the panel of the petty-jury is called over.

After the jury are sworn, and the indictment is read over to them, and they are charged, the evidences on both sides, for and against the prisoner, are called, sworn, and examined in open court; after which the jury bring in their verdict; and if they find the prisoner guilty, their verdict is recorded, and the prisoner is taken from the bar: but if they bring him in not guilty, the prisoner is discharged. On the prisoner being brought in guilty, proclamation is made for all persons to keep silence, upon which the prisoner is again brought to the bar, and the verdict repeated: after which sentence is passed on him, and an order or warrant is made for his execution.

The methods of trial, in our civil courts, are as follows: viz. The declaration is first drawn for the plaintiff, and when the appearance of the defendant is entered, it has been usual to deliver it with an imparlance to the defendant's attorney; and the term following, rule is to be given with the secondary for the defendant to plead by such a day, or else the plaintiff is to have judgment: and the defendant having pleaded, a copy of the issue is made by the plaintiff, and delivered to the defendant's attorney, at the same time giving him notice of the trial; in order to which the venire facias must be taken out and returned by the sheriff: and likewise the habeas corpora, or distringas, to bring in the jury; on which the record is made up, and the parties proceed to trial by their counsel and witnesses; and the jury give in their verdict, &c. But in case the defendant neglects to plead, and suffers it to go by default, on entering such a judgment, a writ of inquiry of damages is awarded returnable next term, notice of the execution whereof the defendant's attorney is to have; and which being executed, and the damages inserted in a schedule annexed to the writ, a rule is given, and costs are taxed by the prothonotary, &c.

TRIANDRIA, in the Linnæan system of botany, a class of plants, the third in order; comprehending all such plants as have hermaphrodite flowers, with three stamina, or male parts, in each; whence the name. See BOTANY.

TRIANGLE, in geometry, a figure bounded or contained by three lines or sides, and which consequently has three angles, from whence the figure takes its name.

Triangles are either plane, or spherical, or curvilinear. Plane when the three sides of the triangle are right lines; but spherical when some or all of them are arcs of great circles on the sphere.

Plane triangles take several denominations, both from the relation of their angles, and of their sides, as below. See GEOMETRY.

The chief properties of plane triangles are as follow, viz. In any plane triangle,

1. The greatest side is opposite to the greatest angle, and the least side to the least angle, &c. Also, if two sides are equal, their opposite angles are equal; and if the triangle is equilateral, or has all its sides equal, it will also be equiangular, or have all its angles equal to one another. 2. Any side of a triangle is less than the sum, but greater than the difference, of the other two sides. 3. The sum of all the three angles, taken together, is equal to two right angles. 4. If one side of a triangle is produced out, the external angle, made by it and the adjacent side, is equal to the sum of the two opposite internal angles. 5. A line drawn parallel to one side of a triangle, cuts the other two sides proportionally, the corresponding segments being proportional, each to each, and to the whole sides; and the triangle cut off is similar to the whole triangle.

If a perpendicular is let fall from any angle of a triangle, as a vertical angle, upon the opposite side as a base; then, 6. The rectangle of the sum and difference of the sides, is equal to twice the rectangle of the base and the distance of the perpendicular from the middle of the base. Or, which is the same thing in other words, 7. The difference of the squares of the sides, is equal to the difference of the squares of the segments of the base. Or, as the base is to the sum of the sides, so is the difference of the sides to the difference of the segments of the base. 8. The rectangle of the legs or sides is equal to the rectangle of the perpendicular and the diameter of the circumscribing circle.

If a line is drawn bisecting any angle, to the base or opposite side; then, 9. The segments of the base, made by the line bisecting the opposite angle, are proportional to the sides adjacent to them. 10. The square of the line bisecting the angle, is equal to the difference between the rectangle of the sides and the rectangle of the segments of the base.

If a line is drawn from any angle to the middle of the opposite side, or bisecting the base, then, 11. The sum of the squares of the sides, is equal to twice the sum of the squares of half the base and the line bisecting the base. 12. The angle made by the perpendicular from any angle and the line drawn from the same angle to the middle of the base, is equal to half the difference of the angles at the base. 13. If through any point within a triangle three lines are drawn parallel to the three sides of the triangle, the continual products or solids made by the alternate segments of these lines will be equal. 14. If three lines are drawn from the three angles through any point within a triangle, to the opposite sides; the solid products of the alternate segments of the sides are equal, viz. 15. Three lines drawn from the three angles of a triangle to bisect the opposite sides, or to the middle of the opposite sides, do all intersect one another in the same point, and that point is the centre of gravity of the triangle; and the distance of that point from any angle is equal to double the distance from the opposite side, or one segment of any of these lines is double the other segment: moreover the sum of the squares of the three bisecting lines is $\frac{3}{4}$ of the sum of the squares of the three sides of the triangle. 16. Three perpendiculars bisecting the three sides of a triangle, all intersect in one point, and that point is the centre of the circumscribing circle. 17. Three lines bisecting the three angles of a triangle, all intersect in one point, and that point is the centre of the inscribed circle. 18. Three perpendiculars drawn from the three angles of a triangle upon the opposite sides, all intersect in one point. 19. Any triangle may have a circle circumscribed about it, or touching all its angles, and a circle inscribed within it, or touching all its sides. 20. The square of the side of an equilateral triangle is equal to three times the square of the radius of its circumscribing circle. 21. If the three angles of one triangle are equal to the three angles of another triangle, each to each, then those two triangles are similar, and their like sides are proportional to one another, and the areas of the two triangles are to each other as the squares of their like sides. 22. If two triangles have any three parts of the one (except the three angles) equal to three corresponding parts of the other, each to each, those two triangles are not only similar, but also identical, or having all their six corresponding parts equal, and their areas equal. 23. Triangles standing upon the same base, and between the same parallels, are equal; and triangles upon equal bases, and having equal altitudes, are equal. 24. Triangles on equal bases, are to one another as their altitudes, and triangles of equal altitudes are to one another as their bases; also equal triangles have their bases and altitudes reciprocally proportional. 25. Any triangle is equal to half its circumscribing parallelogram; or half the parallelogram on the same or an equal base, and of the same or equal altitude. 26. Therefore the area of any triangle is found by multiplying the base by the altitude, and taking half the product. 27. The area is also found thus: Multiply any two sides together, and multiply the product by the sine of their included angle, to radius 1 and divided by 2. 28. The area is also otherwise found thus, when the three sides are given: Add the three sides together, and take half their sum; then from this half sum subtract each side severally, and multiply the three remainders and the half sum continually together; then the square root of the last product will be the area of the triangle. 29. In a right-angled triangle, if a perpendicular is let fall from the right angle upon the hypothenuse, it will divide it into two other triangles similar to one another, and to the whole triangle. 30. In a right-angled triangle, the square of the hypothenuse is equal to the sum of the squares of the two sides; and, in general, any figure described upon the hypothenuse is equal to the sum of two similar figures described upon the two sides. 31. In an isosceles triangle, if a line is drawn from the vertex to any point in the base, the square of that line, together with the rectangle of the segments of the base, is equal to the square of the side. 32. If one angle of a triangle is equal to 120°, the square of the base will be equal to the squares of both the sides, together with the rectangle of those sides; and if those sides are equal to each other, then the square of the base will be equal to three times the square of one side, or equal to twelve times the square of the perpendicular from the angle upon the base. 33. In the same triangle, viz. having one angle equal to 120°, the difference of the cubes of the sides about that angle, is equal to a solid contained by the difference of the sides and the square of the base; and the sum of the cubes of the sides is equal to a solid contained by the sum of the sides and the difference between the square of the base and twice the rectangle of the sides.

TRIANGULAR COMPASSES, are such as have three legs, or feet, whereby to take off any triangle at once; much used in the construction of maps, globes, &c.

TRIANGULAR NUMBERS, are a kind of polygonal numbers. being the sums of arithmetical progressions, which have 1 for the common difference of their terms.

Thus, from these arithmeticals 1 2 3 4 5 6, are formed the triang. numb. 1 3 6 10 15 21, or the third column of the arithmetical triangle abovementioned.

The sum of any number n of the terms of the triangular numbers, 1, 3, 6, 10, &c, is =

$$\frac{n^3}{6} + \frac{n^2}{2} + \frac{n}{3}, \text{ or } \frac{n}{1} \times \frac{n+1}{2} \times \frac{n+2}{3}$$

which is also equal to the number of shot in a triangular pile of balls, the number of rows, or the number in each side of the base, being n.

The sum of the reciprocals of the triangular series, infinitely continued, is equal to 2; viz.,

$$1 + \tfrac{1}{3} + \tfrac{1}{6} + \tfrac{1}{10} + \tfrac{1}{15} \text{ \&c} = 2.$$

For the rationale and management of these numbers, see Simpson's Algebra, sect. 15.

TRIANGULAR CANON, the tables of artificial sines, tangents, secants, &c.

TRIANGULAR QUADRANT, is a sector furnished with a loose piece, whereby to make it an equilateral triangle.

The calendar is graduated thereon, with the sun's place, declination, and other useful lines; and by the help of a string and a plummet, and the divisions graduated on the loose piece, it may be made to serve for a quadrant.

TRIANTHEMA, a genus of the class and order decandria digynia. The calyx is mucronate below the tip; no corolla; stamina 5 or 10; germ. retuse; capsule cut round. There are seven species.

TRIBULUS, *caltrops*, a genus of the decandria-monogynia class of plants, the corolla of which consists of five oblong, obtuse, and patent petals: its fruit is of a roundish figure and aculeated, being composed of five capsules, gibbous on one side, and armed with three or four points on the other, angulated and convergent; and containing numerous seeds, turbinated and oblong. There are four species.

TRICEPS. See ANATOMY.

TRICERA, a genus of the class and order monoecia tetrandria. There is no corolla; the male is four-leaved; filaments four, ovate; female calyx five-leaved; styles conical; capsules three, horned, three-celled. There is one species, a shrub of Jamaica.

TRICHECHUS, *walrus*, a genus of quadrupeds of the order bruta. The generic character is, fore-teeth (in the full-grown animal) none either above or below; tusks solitary, in the upper jaw; grinders with wrinkled surfaces; lips doubled; hind feet at the extremity of the body, uniting into a fin. The genus trichechus is entirely marine, and contains but three species, besides varieties: of these the principal is the trichechus rosmarus, or, as it is sometimes called, the sea-horse, or walrus.

1. Trichechus rosmarus, arctic walrus. This animal inhabits the northern seas, and is principally found within the arctic circle. It grows to a very large size, having been sometimes seen of the length of eighteen feet, and of such a thickness as to measure twelve feet round the middle of the body. The walrus is of an inelegant form; having a small head, short neck, thick body, and short legs: the lips are very thick, and the upper lip is indented or cleft into two large rounded lobes: over the whole surface of this part are scattered numerous semitransparent bristles, of a yellowish tinge, and of such a thickness as almost to equal a straw in diameter: they are about three inches long, and are slightly pointed at their extremities; the eyes are small: instead of external ears there are only two small, round orifices; the skin on the whole animal is thick, and more or less wrinkled and is scattered over with short brownish hair: on each foot are five toes, all connected by webs, and on each toe is a small nail: the hind feet are considerably broader than the fore feet: the tail is extremely short. In the upper jaw are two large and long tusks, bending downwards: there are no cutting-teeth; but in each jaw, both above and below, are four roundish grinders with flat tops: the tusks are sometimes upwards of two feet in length, but are more generally of about one foot long: and it sometimes happens that the two tusks are not perfectly equal in length. The chief resorts of the walrus are the seas about the northern parts of America. They are found in the gulph of St. Laurence according to Mr. Pennant, between latitude 47 and 48. They are also found in Davis's Straits and within Hudson's Bay, lat. 62. They inhabit the coast of Greenland; and are found in great numbers about Spitsbergen, and on the floating ice in those parts. They occur likewise on the coasts of Nova Zembla, and on the headlands stretching towards the north pole.

They are gregarious animals, and are sometimes seen in vast multitudes on the masses of floating ice so frequent in the northern seas. They are said to produce their young early in the spring, and rarely bring more than one at a birth: their food consists of sea-plants, shell-fish, &c.

The walrus is a harmless animal, unless provoked or attacked, in which case it becomes furious, and is extremely vindictive. When surprised upon the ice, the female is said first to provide for the safety of the young, by flinging it into the sea, and immediately precipitating itself after it; carrying it to a secure distance, and then returning, with great rage, to revenge the injury. They will sometimes attempt to fasten their teeth on the boats, with an intent to sink them; or rise in numbers under them to overset them; at the same time shewing all the marks of rage, by roaring in a dreadful manner, and gnashing their teeth with great violence; if once thoroughly irritated, the whole herd will follow the boats till they lose sight of them. They are strongly attached to each other; and it is said that a wounded walrus has been known to sink to the bottom, rise suddenly up again, and bring with it multitudes of others, which have united in an attack upon the boat whence the insult came.

The teeth of the walrus are used as ivory; but on this subject authors seem to vary considerably; some representing them as superior to common ivory, and others greatly inferior, and more subject to turn yellow. The animals are now killed chiefly for the sake of the oil; and it is said that a very strong and elastic leather may be prepared from the skin. See Plate Nat. Hist. fig. 404.

2. Trichechus dugong, Indian walrus. This species is a native of the seas about the Cape of Good Hope and the Philippine islands. It does not, however, seem to be very clearly known to naturalists. The grinders differ from those of the walrus, being broader in proportion: of these there are four on each side in the upper jaw, and three in the lower. The head is said to be of a sharper or narrower form. This species, in the Philippine Islands, is said to be called by the name of dugung.

3. Trichechus borealis, manate or whale-tailed trichechus. This animal seems to approach so nearly to the cetaceous or whale tribe, as scarcely to deserve, according to Mr. Pennant, the name even of a biped; what are called the feet being little more than pectoral fins, which serve only for swimming, and are never used to assist the animal either in walking or landing; for it never goes ashore, nor ever attempts to climb the rocks like the walrus and the seal. It brings forth in the water, and, like the whale, suckles its young in that element. Like the whale, it is also destitute of voice; and has also a horizontal tail, which is broad, and of the form of a crescent, without even rudiments of hind feet.

So complete is the account given by Mr. Pennant of this animal, that we shall here deliver the most material parts of that author's description, rather than attempt a new one.

It inhabits the seas about Berings and the other Aleutian islands, which intervene between Kamtschatka and America, but never appears off Kamtschatka, unless blown ashore by a tempest. It is probably the same species which is found above Mindanao, but is certainly that which inhabits near Rodiguez, vulgarly called Diego Reys, an island to the east of Mauritius, or the Isle of France, near which it is likewise found. It is also probable that it extends to New Holland. They live perpetually in the water, and frequent the edges of the shores; and, in calm weather, swim in great droves near the mouths of rivers: in the time of flood they come so near the land that a person may stroke them with his hand: if hurt, they swim out to the sea, but presently return again. They live in families, one near another; each consists of a male, a female, a half-grown young one, and a very small one. The females oblige the young to swim before them, while the other old ones surround, and, in a manner, guard them on all sides. The affection between the male and female is very great; for if she is attacked, he will defend her to the utmost; and if she is killed, will follow her corpse to the very shore, and swim for some days near the place it has been landed at.

They are vastly voracious, and feed not only on the fuci that grow in the sea, but such as are flung on the edges of the shore. When they are filled, they fall asleep on their backs. During their meals they are so intent on their food, that any one may go among them, and choose which he likes best. Their back and sides are generally above water; and numbers of gulls, from time to time, perch on their backs, in order to pick the insects which they find upon them.

They continue in the Kamtschatkan and American seas the whole year; but in winter they are very lean, so that one may count their ribs. They are taken by harpoons fastened to a strong cord; and after they are struck, it requires the force of thirty men to draw them on shore. Sometimes, when they are transfixed, they will lay hold of the rocks with their paws, and stick so fast as to leave the skin behind before they can be forced off. When a manati is struck, its companions swim to its assistance: some will attempt to overturn the boat, by getting under it; others will press down the rope, in order to break it; and others will strike at the harpoon with their tails, with a view of getting it out, in which they often succeed. They have no voice; but make a noise, by hard breathing, like the snorting of a horse.

They are of an enormous size: some are twenty-eight feet long, and eight thousand pounds weight: but, if the Mindanao species is the same with this, it decreases in size as it advances southward, for the largest which Dampier saw there weighed only six hundred pounds. The head, in proportion to the bulk of the animal, is small, oblong, and almost square: the nostrils are filled with short bristles; the gape or rictus is small; the lips are double; near the junction of the two jaws the mouth is full of white tubular bristles, which serve the same purpose as the laminæ in whales, to prevent the food from running out with the water: the lips are also full of bristles, which serve instead of teeth to cut the strong roots of sea-plants, which, floating ashore, are a sign of the vicinity of these animals. In the mouth are no teeth; only two flat white bones, one in each jaw, one above, another below, with undulated surfaces, which serve instead of grinders.

The eyes are extremely small, not larger than those of a sheep: instead of ears are only two minute orifices, which will scarcely permit a quill to enter: the tongue is pointed and small: the neck thick, and its junction with the head scarcely distinguishable; and the last always hangs down.

The circumference of the body near the shoulders is twelve feet; about the belly twenty; near the tail only four feet eight inches: the head thirty-one inches: the neck near seven feet: and from these measurements may be collected the deformity of the animal. Near the shoulders are two feet, or rather fins, which are only two feet two inches long, and have neither fingers nor nails; beneath they are concave, and covered with hard bristles; the tail is thick, strong, and horizontal, ending in a stiff black fin, and like the substance of whalebone, being much split on the fore part and slightly forked; but both ends are of equal length like the whale.

The skin is very thick, hard, and black; full of inequalities, like the bark of oak; so hard as scarcely to be cut with an ax, and has no hair upon it: beneath the skin is a thick blubber, which is said to taste like oil of almonds. The flesh is coarser than beef, and will not soon putrefy: the young ones taste like veal: the skin is used for shoes, and for covering the sides of boats. The Russians call this animal morskaia korowa or sea-cow, and kapustnik or eater of herbs.

4. Trichechus australis, round-tailed manati. This species grows to the length of fourteen or fifteen feet, and is found in the rivers of Africa; particularly in the river Senegal: the lips are thick; the eyes as small as peas; and there are two very small orifices in the place of ears: in each jaw on each side are nine grinding teeth, in all thirty-six: the neck is short and thicker than the head: the greatest thickness of the body is about the should- from whence it gradually tapers to the tail, which is horizontal, broad, thickest in the middle, growing thinner to the edges, and quite round. The feet are placed at the shoulders; and beneath the skin are bones for five complete toes, and externally are three or four nails, flat and rounded: near the base of each leg, in the female is a small teat. The flesh of this animal is said to resemble veal: it is, however, chiefly killed by the negroes for the sake of the blubber or fat.

TRICHIURUS, a genus of fishes of the order apodes; the generic character is, head stretched forwards, with lateral gill-covers; teeth ensiform, semisagittate at the tips; gill-membrane seven-rayed; body ensiform, compressed, with subulate finless tail.

1. Trichiurus argenteus, silver trichiure. This fish is equally distinguished by the singularity of its shape, and brilliancy of its colour: the body is extremely compressed, of a great length, and gradually tapers as it approaches the extremity, till at length it terminates in a very fine point: the whole fish, except on the fins, is of the brightest silver-colour: the head is narrow; the mouth very wide, the lower jaw longer than the upper, and furnished with differently sized teeth, the longest of which are barbed at the tips by a sharp descending process or hook on one side: the tongue is smooth, longish, and triangular: in the throat are two rough bones: the eyes are vertical, approximated, and large: the lateral line is of a gold-colour, and, commencing behind the gill-covers, is continued to the tip of the tail: the dorsal fin, which is of moderate width, transparent, and of a yellowish tinge, commences almost immediately behind the head, and runs to within a very small distance of the extremity of the tail, at which part it degenerates into a mere membrane, being strongly radiated in other parts: the pectoral fins are rather small, and of an ovate shape: there is, properly speaking, no direct vent-fin, but a series of very small naked spines or rays, to the number of about 110, are continued from the vent, which is situated about the middle of the body, to near the tip of the tail. The general length of this fish is from two to three feet: it is said to be of a very voracious nature, swims with rapidity, and in the pursuit of its prey sometimes leaps into small vessels which happen to be sailing by. It is a native of the rivers and larger lakes of South America, and is considered as an eatable fish. It is also said to be found in some parts of India, and in China. See Plate Nat. Hist. fig. 407.

2. Trichiurus electricus, electrical trichiure. This species, which seems nearly equal in size to the preceding, differs not only in the conformation of the jaws, which are both of equal length, but in the form of its teeth, which are all very minute: the tail is not so extremely slender and sharp as in the former, and the colour of the whole animal is pale brown, variegated with spots of a deeper cast. It is a native of the Indian seas, and is said to possess a degree of electrical power. There are only these two species.

TRICHODA, a genus of vermes infusoria; the generic character is, a worm invisible, pellucid, hairy or horned. Ample accounts of this genus, which is very numerous, will be found in Adams's work on the Microscope. See Plate Nat. Hist. fig. 406. There are about sixty species.

TRICOCEPHALUS, a genus of vermes intestina. The generic character is, body round, elastic, and variously twisted; head or fore part much thicker, and furnished with a slender exsertile proboscis; tail or lower part long, capillary, and tapering to a fine point. There are six species: T. hominis, see Plate Nat. Hist. fig. 405, inhabits the intestines of sickly children, generally the cæcum, and in considerable numbers: about two inches long and resembling the ascarides in colour. The other species are named from animals on which they live, as the equi, apri, muris, vulpis, and lacertæ.

TRICHILIA, a genus of the class and order decandria monogynia. The calyx is mostly five-toothed; petals five; nectarium toothed; capsules three-celled, three-valved; seeds berried. There are 12 species, trees chiefly of the West Indies.

TRICHOCARPUS, a genus of the class and order polyandria digynia. The calyx is four or five parted; no corolla; styles two, bifid; capsules bristly, four-valved, many-seeded. These is one species, a tree of Guiana.

TRICHOMANES, a genus of plants of the class cryptogamia, and order filices. The parts of fructification are solitary; and terminated by a stile like a bristle, on every edge of the leaf. There are 27 species; of which two are natives of Britain, the pixidiferum and tunbrigense. 1. Pixidiferum, or cup-trichomanes, has subbipinnated leaves, the pinnæ being alternate, close-lobed and linear. It is found among stones in wet grounds in England. 2. Tunbrigense, or Tunbridge trichomanes, has pinnated leaves, the pinnæ being oblong, dichotomous, decurrent, and dentated. It is found in the fissures of moist rocks in Wales, and in many rocky places in Scotland.

TICOCCEÆ, the name of the 38th order in Linnæus's Fragments of a Natural Method, consisting of plants with a single three-cornered capsule, having 3 cells or internal divisions, each containing a single seed. See Botany.

TRICOSANTHES, a genus of plants of the class monœcia, and order syngenesia, and in the natural system ranging under the 34th order, cucurbitaceæ. There are seven species; only one of which is cultivated in the British gardens, the anguina or snake-gourd, which is a native of China, an annual, and of the cucumber tribe.

TRICOSTEMA, a genus of the didynamia gymnospermia class of plants, with a monopetalous ringent and falcated flower. The stamina are four extremely long filaments; and four roundish seeds are contained in the cup. There are three species.

TRIDAX, a genus of the syngenesia polygamia superflua class of plants, with a radiated flower, and the lesser hermaphrodite ones of the disc monopetalous, and funnel-fashioned. The seeds are winged with down, and contained in the cup. There is one species.

TRIENTALIS, *chickweed winter-green*, a genus of plants of the class heptandria, and order monogynia, and in the natural system ranging under the 20th order, rotaceæ. The calyx is heptaphyllous; the corolla is equal and plane, and is divided into seven segments; the berry is unilocular and dry. There is only one species, the europæa, which is indigenous, and the only genus of heptandria that is so. The stalk is single, five or six inches high, terminated with five, six, or seven oval pointed leaves; from the centre of which arise on long footstalks commonly two white starry flowers, each generally consisting of seven oval and equal petals, succeeded by a globular dry berry, covered with a thin white rind, having one cell, and containing several angular seeds.

TRIFOLIUM, *trefoil* or *clover*, a genus of plants of the class diadelphia, and order decandria, and in the natural system ranging under the 32d order, papilionaceæ. The flowers are generally in round heads; the pod is scarcely longer than the calyx, univalve, not opening, deciduous. The leaves are three together. There are 51 species; of which 17 are natives of Britain. We shall describe some of the most remarkable of these:

1. Officinale or melilot, has naked racemous pods, dispermous, wrinkly, and acute, with an erect stalk. It grows in corn-fields, and by the way-sides, but not common. The stalk is erect, firm, striated, branched, and two or three feet high; the leaves ternate, smooth, obtusely oval, and serrated; the flowers are small, yellow, pendulous, and grow in long close spikes at the tops of the branches; the pod is very short, turgid, transversely wrinkled, pendulous, and contains either one or two seeds. The plant has a very peculiar strong scent, and disagreeable, bitter, acrid taste, but such, however, as is not disagreeable to cattle. The flowers are sweet-scented. It has generally been esteemed emollient and digestive, and been used in fomentations and cataplasms, particularly in the plaster employed in dressing blisters; but is now laid aside, as its quality is found to be rather acrid and irritating than emollient or resolvent. It communicates a loathsome flavour to wheat and other grain, so as to render it unfit for making bread.

2. Trifolium repens, white creeping trefoil, or Dutch clover, has a creeping stalk, its flower gathered into an umbellar head, and its pods tetraspermous. It is very common in fields and pastures. It is well known to be excellent fodder for cattle; and the leaves are a good rustic hygrometer, as they are always relaxed and flaccid in dry weather, but erect in moist or rainy.

3. Trifolium pratense, purple or red clover, is distinguished by dense spikes, unequal corollas, by bearded stipulas, ascending stalks, and by the calyx having four equal teeth. The red clover is common in meadows and pastures, and is the species which is generally cultivated as food for cattle. It abounds in every part of Europe, in North America, and even in Siberia. It delights most in rich, moist, and sunny places, yet flourishes in dry, barren, and shady places. See HUSBANDRY.

4. Alpestre, long-leaved purple trefoil, or mountain-clover. The spikes are dense; the corollas somewhat equal; the stipulas are bristly and divergent; the leaflets lanceolated; the stalks stiff, straight, and very simple. It grows in dry, mountainous, woody places, in Hungary, Austria, and Bohemia, &c.; but is not said to be a native of Britain.

5. The medium has been confounded with the two species last mentioned; but it is to be distinguished from them by having loose spikes, corollas somewhat equal, stipulas subulate and connivent, and stalks flexuose and branched. It is found in dry elevated situations, especially among shrubs, or in woods where the soil is chalky or clay, in England, Scotland, Sweden, Denmark, &c.

TRIGLA, *gurnard*, a genus of fishes of the order of thoracici. The generic character is, head large, mailed, and marked by rough lines; gill-covers spiny; gill-membrane seven-rayed; finger-shaped processes, in most species, near the pectoral fins.

1. Trigla gurnardus, grey gurnard. Length from one to two feet, or more; colour above deep grey, with blackish and red spots, beneath silvery; scales small; lateral line very strongly marked, and consisting of a series of larger, rounded, whitish scales with a dusky central spot. Native of the European seas, and not uncommon about our own coasts, feeding on worms, insects, &c.

2. Trigla lyra, piper gurnard. Size nearly equal to the former species; lateral line formed of small scales; colour bright rose-red, silvery beneath; scales small; pectoral fins large, and slightly tinged with dull blue; tail of similar colour; the other fins yellowish, with red rays. Native of the European seas, and considered as an excellent fish for the table.

3. Trigla cuculus, cuckow gurnard. An elegant species. Length about a foot; shape more slender than in the preceding kinds; colour, on the upper parts, a beautiful red, more or less distinctly marked by whitish transverse bars, beneath silvery; scales extremely small; lateral line composed of pointed white scales edged with black; a similar row on each side the back; fins transparent; the first dorsal marked on the edge by a black spot, the second tinged near its edge with yellow. Native of the European seas, and esteemed as a food.

4. Trigla hirundo, sapphirine gurnard. Size equal to that of the grey gurnard; scales middle-sized; lateral line rough; pectoral fins very large, of a violaceous olive, sometimes, according to Mr. Pennant, richly edged and spotted with blue. Native of the European seas, occasionally springing out of the water to some distance by means of its large pectoral fins.

5. Trigla volans, flying gurnard. A highly singular and beautiful species. Length about twelve inches; colour crimson above, pale or whitish beneath; head blunt, and armed on each side with two very strong and large spines, pointing backwards; whole body covered with extremely strong carinated and sharp-pointed scales, so united as not to be distinctly separable; first dorsal fin pale violet, crossed with deeper lines, and at its origin two separate rays longer than the rest; second dorsal fin pale, with the rays barred with brown; pectoral fins extremely large, transparent, of an olive-green, richly varied with numerous bright-blue spots; pectoral processes six in number, and not separate, as in other species, but united into the appearance of a small fin on each side the thorax; tail pale-violet, with the rays crossed by dusky spots, and strengthened on each side the base by two obliquely transverse bony ribs or bars. Native of the Mediterranean, Atlantic, and Indian seas, where it swims in shoals, and is often seen flying out of the water to a considerable distance, in the manner of the genus exocœtus. There are in all 14 species.

TRIGLOCHIN, a genus of plants of the class hexandria, and order trigynia, and in the natural system ranging under the fifth order, tripetaloidæ. The calyx is triphyllous; the petals are three; there is no style; the capsule opens at the base. There are three species, of which the palustre and maritimum are British.

1. Palustre, or harrow-headed grass, has an oblong trilocular capsule. The stalk is simple, eight or ten inches high; the leaves long and narrow; the flowers are greenish, and grow at the end of a long spike. It is frequent in moist ground.

2. Maritimum, or sea-spiked grass, has ovate sexlocular capsules; the stalk is short; the spike long, and flowers purplish. It is frequent on the sea-coasts. Linnæus says that cattle eat these two species with avidity.

TRIGONELLA, *fenugreek*, a genus of plants of the class diadelphia, and order decandria, and in the natural system arranged under the 32d order, papilionaceæ. The vexillum and alæ are nearly equal and patent, resembling a tripetalous corolla. There are 12 species, of which the most remarkable is the fœnumgræcum, or fenugreek, a native of Montpelier, in France. Fenugreek is an annual plant, which rises with a hollow, branching, herbaceous stalk, a foot and a half long, with trifoliate leaves, placed alternately, whose lobes are oblong, oval, indented on their edges, and have broad furrowed footstalks. Fenugreek seeds have a strong disagreeable smell, and an unctuous farinaceous taste, accompanied with a slight bitterness. The principal use of these seeds is in cataplasms and fomentations, for softening, maturating, and discussing tumours; and in emollient and carminative clysters. They are an ingredient in the oleum e mucilaginibus of the shops, to which they communicate a considerable share of their smell, but this is not now in use.

TRIGONIA, a genus of the diadelphia decandria class and order of plants. The calyx is five-parted; petals five, unequal; nect. two scales at the base of the germ; filaments some barren; capsules leguminous, three-cornered, three-celled, three-valved. There are two species, of Guiana.

TRIGONOMETRY is that part of geometry which teaches how to measure the sides and angles of triangles. Trigonometry is either plane or spherical, of each of which we shall treat in order.

Plane Trigonometry is the science which treats of the analogies of plane triangles, and of the methods of determining their sides and angles. For this purpose, it is not only requisite that the peripheries of circles, but also that certain right lines in and about a circle, are supposed to be divided into some assigned number of equal parts. These lines are denominated sines, tangents, secants, &c. The sides of plane triangles may be estimated in feet, yards, chains, or by any other definite measures, or by abstract numbers: but the angles are measured by the arcs of a circle, contained between the two legs, having the angular point for its centre.

Every circle is supposed to be divided into 360 equal parts, called degrees; each degree into 60 equal parts, called minutes; each minute into 60 equal parts, called seconds. An angle is said to be of as many degrees, minutes, seconds, &c. as are contained in the arc, or part of the circumference, by which it is measured.

A right angle is measured by the fourth part of the circumference, or 90°; an obtuse angle is greater than 90°, and an acute angle is less than 90°. Degrees, minutes, &c. are marked at the top of the figures by which the are is denoted. Thus we say $34^{\circ}\ 28'\ 50''$, thirty-four degrees, twenty-eight minutes, and fifty seconds.

The difference of an arc from 90°, or a quadrant, is called its *complement*; and its difference from 180°, its *supplement*: thus in Plate Miscel. fig. 246, the arc AB is the complement of HB: but AB is the supplement of BD.

A *chord*, or subtense, is a right line drawn from one extremity of an arc to the other: thus BE is the chord or subtense of the arc BAE, or BDE.

The *sine*, or, as it is sometimes called, the *right sine*, of an arc, is a right line drawn from one extremity of the arc, perpendicular to the diameter passing through the other extremity: thus BF is the sine of the arc AB, or BD.

The *versed sine* of an arc is the part of the diameter, intercepted between the arc and its sine: AF is the versed sine of AB, and DF of the arc DB.

The *co-sine* of an arc is the part of the diameter intercepted between the center and the sine, and is equal to the sine of the complement of that arc. Thus CF is the co-sine of the arc AB, and is equal to BI, the sine of its complement HB.

The *tangent* of an arc, is a right line touching the circle in one extremity of that arc, continued from thence to meet a line drawn from the center through the other extremity; which line is called the *secant* of the same arc: thus AG is the tangent, and CG the secant of the arc AB.

The *co-tangent* and *co-secant* of an arc, are the tangent and secant of the complement of that arc: thus HK and CK are the co-tangent and co-secant of the arc AB.

The lines here described, belong equally to an angle as to the arc by which it is measured; and, except the chords and versed sines, they are all common to two arcs or angles which are the supplements of each other.

So that if the sine, tangent, &c. of any arc or angle above 90° are required, it is the same thing as to find the sine, tangent, &c. of its supplement, or what it wants of 180°.

They are also called the natural sines, tangents, &c. of the arcs or angles to which they belong; and the logarithms of the numbers by which they are represented, are the logarithmic sines, tangents, &c.

And as one or other of these lines make a part of every trigonometrical operation, they have been calculated to a given radius, for every degree, minute, &c. of the quadrant, and ranged in tables for use.

Whence, by the help of such a table, the sine, tangent, &c. of any arc or angle, may be found by inspection; and, vice versa, the arc, or angle, to which any sine, tangent, &c. belongs.

Upon this table also, and the doctrine of similar triangles, depends the solution of the several cases of plane trigonometry, which may be performed either by the natural or logarithmic sines, tangents, &c., as occasion requires.

But the logarithmic sines, tangents, &c., are those most commonly used; as the calculations, in this case, are all performed by adding and subtracting only, instead of multiplying and dividing, as is required by the natural sines, &c.

The sine, tangent, &c. of any arc or angle being of the same magnitude as the sine, tangent, &c. of its supplement, it is plain that a table of these lines made for every degree, minute, &c. of the quadrant, or 90°, will serve for the whole circle.

It is also to be observed that, in every such table, the natural sines, tangents, &c. are usually calculated to radius 1; but in order that the logarithmic sines, tangents, &c. may be all positive, they are calculated to radius 1.0000000000, or 1 with 10 cyphers, the logarithm of which is 10, so that the latter are the logarithms of the former, with 10 added to the index.

And, as the natural sines, tangents, &c. of any angles or arcs of different circles, are proportional to the radii of those circles, their values may be readily found, or made to correspond to any radius whatever.

In every plane triangle, three things must be given to find the rest; and of these three one at least must be a side, because the same angles are common to an infinite number of triangles.

It is also to be observed, that all the varieties that can possibly happen in the solution of plane triangles, are comprised under the three following cases: viz.

1. When two of the three given things are a side and its opposite angle.
2. When two sides and their included angle are given.
3. When the three sides are given.

Each of which cases may be resolved, either by geometrical construction, by arithmetical computation, or instrumentally.

In the first of these methods, the triangle is constructed, by laying down the sides from a scale of equal parts, and the angles from a scale of chords, or a protractor, and then measuring the unknown parts by the same scale or instrument from which the others were taken.

In the second method, having stated the proportion, according to the proper rule, multiply the second and third terms together, and divide the product by the first, and the quotient will be the fourth term required, for the natural numbers. Or, in working by logarithms, add the logarithms of the second and third terms together, and from the sum take the logarithm of the first, and the number answering to the remainder will be the fourth term sought.

In the third method, or instrumentally, as suppose by the logarithmic lines on one side of the common two-foot scales, extend the compasses from the first term to the second or third as they happen to be of the same kind; and that extent will reach from the other term to the fourth term required, taking both extents towards the same end of the seale.

The second of these methods, however, or that in which the operation is performed by logarithms, is the one generally employed; the other two being chiefly of use as checks on the calculations, or, in certain simple cases, where a near approximate value of the quantities to be determined is thought sufficient.

It may here also be further remarked, that when one or more logarithms are to be subtracted, in any operation, it will be better to write down their *complements*, or what each of them wants of 10.0000000 instead of the logarithms themselves, and then add them together, abating as many tens in the index of the sum as there were logarithms to be subtracted.

Thus, if the logarithm to be subtracted is 3.4932758, it will be the same thing as to add its complement 6.5067242; and if it is 9.07432600, its complement, or the number to be added, will be 0.92567400; which numbers are readily found by beginning at the left hand and subtracting each figure of the logarithm from 9, except the last significant figure on the right, which must be subtracted from 10.

If the index of the logarithm, whose complement is to be taken, is greater than 10, write down what the index wants of 19, and the rest of the figures as before; and, after the addition, subtract 20 from the index of the sum. And if the logarithm of a decimal is to be subtracted, add 10 to the index, and then take the complement of the resulting number, and the rest of the figures, as before.

Thus the complement of the logarithm 12.4907327 is 7.5092673; and the complement of the logarithm of 3.5972648 is 2.4027352.

PROPERTIES OF PLANE TRIANGLES, REQUIRED IN THE PRACTICAL PART OF THIS SCIENCE.

The sum of all the three angles of any plane triangle is equal to two right angles, or 180°.

The greater side is opposite to the greater angle; and the less side to the less angle.

The sum of any two sides is greater than the third; and the difference of any two sides is less than the third.

The triangle is equilateral, isosceles, or scalene, according as its three angles are all equal, or only two of them equal, or all three unequal.

The angles opposite to the two least sides are acute; and if there is an obtuse angle, it is opposite to the greatest side.

A perpendicular drawn from the opposite angle to the longest side will fall within the triangle; and the greater and less segment will be next the greater and less side.

In an isosceles triangle, a perpendicular drawn from the vertex will bisect both the base and the vertical angle.

In a right-angled triangle the hypothenuse is equal to the square root of the sum of the squares of the other two sides; and either of the sides is equal to the square root of the difference of the squares of the hypothenuse and the other side.

Note, also, that if the half difference of any two quantities is added to their half sum, it will give the greater of those quantities: and, if it is subtracted from the half sum, it will give the less.

CASE I. When two of the three given things are a side and its opposite angle, to find the rest.

RULE. The sides of any plane triangle are to each other as the sines of their opposite angles, and vice versa:—That is,

As any side is to the sine of its opposite angle, so is any other side to the sine of its opposite angle.

Or, As the sine of any angle is to its opposite side, so is the sine of any other angle to its opposite side.

Hence, to find an angle, begin the proportion with a side opposite to a given angle; and to find a side, begin with an angle opposite to a given side.

Note. When two sides and an angle opposite to one of them are given, to find the rest, the question is sometimes ambiguous, or admits of two different answers.

Thus, if the given angle is opposite to the least of the two given sides, the angle to be found, by the rule, may be either an acute angle or its supplement; but, if it is opposite to the greater side, the required angle will be acute.

Example I. In the plane triangle ABC, fig. 247.

Given { AC 236, BC 350 } yards, ∠ B 38° 40′. Required the other parts.

By Construction.

1. Lay down the line BC = 350, from some convenient scale of equal parts.

2. Make the ∠ B = 38° 40′ by a scale of chords, or other instrument.

3. With the centre C, and radius 236, taken from the same scale of equal parts, cross BA in A or *a*.

4. Join CA or C*a*, and the triangle ABC, or *a*BC, is the one required.

Then, the angles C and A, measured by the scale of chords, and the side BA, or B*a*, by the scale of equal parts, will be found to be as follows, viz.

∠ C $29\frac{1}{4}$°	∠ A $67\frac{3}{4}$°	AB 184
or $73\frac{1}{2}$	or $112\frac{1}{4}$°	or 362

By Calculation.

As side AC	- 236	2.3729120
		7.6270880
Is to sine ∠ B	- 38° 40′	9.7957330
So is side BC	- 350 -	2.5440680
To sine ∠ A	67° 54′ or 112° 6′	9.9668890
	38° 40′ 38° 40′	
Sum	106° 34′ or 150° 46′	
Subtract	180° 0′ 180° 0′	
Leaves	73° 26′ or 29° 14′ ∠ C	

Then,

: Sine ∠ B 38° 40′	-	9.7957330
		0.2042670
: Side AC 236	- -	2.3729120
:: Sine ∠ C 29° 14′	-	9.6887467
: Side AB 184.47	-	2.2659257

Or,

: Sine ∠ B 38° 40′	-	9.7957330
		0.2042670
: Side AC 236	- -	2.3729120
:: Sine ∠ C 73° 26′	-	9.9815870
: Side *a*B 362.04	-	2.5587660

As the results in this rule are determined by means of the sines which are always the same for an acute angle and its supplement, it is plain that, in certain cases, there may be two triangles with the same data; one acute-angled, and the other obtuse-angled: and, consequently, when there is no restriction or limitation in the question, either of them may be taken for the one required.

Thus, in the figure given above, where the least side AC is opposite to the given acute angle B, it appears, from the construction, that either ABC or *a*BC is the triangle sought. But, when the given angle is right or obtuse, it will be opposite to the greatest side, and in this case there can be no ambiguity: for then neither of the other angles can be obtuse, and the geometrical construction will accordingly form only one triangle.

Instrumentally.

In the first proportion, extend the compasses from 236 to 350, upon the line of numbers, and that extent will reach, upon the sines, from $38\frac{2}{3}$° to $67\frac{3}{4}$°, for the ∠ A.

In the second proportion, extend from $38\frac{2}{3}$° to $29\frac{1}{4}$°, or $73\frac{1}{2}$° upon the sines, and that extent will reach, upon the line of numbers, from 236 to 184, or 362, for the side AB, or *a*B.

Example II. In the plane triangle ABC,

Given { AB 131, BC 97, ∠ C 90° } Ans. { AC 88.045, ∠ A 47° 46′, ∠ B 42° 14′ }

Required the other parts.

Example III. In the plane triangle ABC,

Given { BC 305, ∠ B 51° 15′, ∠ C 37° 21; } Ans. { AC 237.93, AB 185.09, ∠ A 91° 24′ }

Required the other parts.

Example IV. In the plane triangle ABC,

Given { AB 195, AC 203, ∠ B 45° } Ans. { ∠ A 92° 13′, ∠ C 42° 47′, BC 286.87 }

Required the other parts.

Example V. In the plane triangle ABC,

Given { BC 345, AC 232, ∠ B 37° 20′ } Ans. { AB 174.07 or 374.56, ∠ C 27° 4′ or 78° 16′, ∠ A 115° 36′ or 64° 24′ }

Required the other parts.

Case II. When two sides and their included angle are given, to find the rest.

Rule. As the sum of any two sides of a plane triangle, is to their difference, so is the tangent of half the sum of their opposite angles, to the tangent of half their difference.

Then the half difference of these angles, added to their half sum, gives the greater angle, and subtracted from it gives the less.

And as all the angles are now known, the remaining side may be found by Case I.

Note. Instead of the tangent of half the sum of the two unknown angles, we may use the cotangent of half the given angle, or the tangent of half its supplement, which are all equal to each other.

Example. In any plane triangle ABC,

Given { AB 1075, BC 2394 } feet, ∠ B 34° 46′. Required the rest.

By Construction. 1. Draw BC = 2394, from a scale of equal parts.

2. Set off the ∠ B = 34° 46′, by a scale of chords, or other instrument.

3. Make AB = 1075, by the same scale of equal parts, as before.

4. Join A, C, and the triangle is constructed.

Then, the parts being measured, we shall have ∠ A = $123\frac{1}{6}$°, ∠ C = $22\frac{1}{12}$°, and side AC = 1630 feet.

By Calculation.

: AB + BC	3469	-	3.5402043
			6.4597957
: AB ∽ BC	1319	-	3.1202448
:: Tan. $\frac{A+C}{2}$	72° 37′	-	10.5043702
: Tan. $\frac{A \backsim C}{2}$	50° 32′	-	10.0844107
Sum	123° 9′ ∠A		
Diff.	22° 5′ ∠C.		

Then,

: Sine ∠ A	123° 9′ or 56° 51′		9.9228509
			0.0771491
: Side BC	- 2394	-	3.3791241
:: Sine ∠B	- 34° 46′	-	9.7560544
: Side AC	- 1630.5	-	3.2123276

Case III. When the three sides are given, to find the angles.

Rule. Make the longest side the base, and let fall a perpendicular upon it from the opposite angle.

Then, as the base, or sum of its segments, is to the sum of the other two sides, so is the difference of those sides, to the difference of the segments of the base.

And half this difference, being added to half the base, will give the greater segment; and, subtracted from it, will give the less.

Then, in each of the right-angled triangles, formed by the perpendicular, there will be known two sides and an angle opposite to one of them; from whence the other angles may be found, by Case I.

Example I. In any plane triangle ABC,

Given { AB 464, AC 348, BC 690 } yards. Required the angles.

By Construction. 1. Draw BC = 690, by a scale of equal parts.

2. With the centres B, C, and radii 464 and 348, taken from the same scale, describe arcs intersecting each other in A.

3. Join AB, AC, and the triangle is constructed.

Then, by measuring the angles with a protractor, or by the scale of chords, they will be found to be nearly as follows, viz. ∠A = $115\frac{1}{2}$°, ∠B = 27°, and ∠C = $37\frac{1}{8}$°.

By Calculation.

Having let fall the perpendicular AD, it will be

: BC or BD + DC	690	-	2.8388491
			7.1611509
: AB + AC	- 812	-	2.9095560
:: AB ∽ AC	- 116	-	2.0644580
: BD ∽ DC	- 136.51	-	2.1351649

Hence $\frac{690 + 136.51}{2} = 413.25 = $ BD.

And $\frac{690 - 136.51}{2} = 276.75 = $ CD.

Then, in the triangle ABD, right-angled at D,

: AB	- 464	-	2.6665180
: BD	- 413.25	-	2.6162129
:: Sine ∠D	- 90°	-	10.0000000
: Sine ∠BAD	62° 57′	-	9.9496949
	90° 0′		
	27° 3′ ∠ B.		

And, in the triangle ACD, right-angled at D,

: AC	- 348	-	2.5415792
: DC	- 276.75	-	2.4420876
:: Sine ∠ D	- 90° 0′	-	10.0000000
: Sine ∠ CAD	52° 40′	-	9.9005084
	90° 0′		
	37° 20′ ∠ C		
Also	62° 57′ ∠ BAD		
And	52° 40′ ∠ CAD		
Makes	115° 37′ ∠ BAC.		

Whence ∠ B = 27° 3′, ∠ C = 37° 25′, and ∠ BAC = 115° 37′.

These three problems include all the cases or varieties of plane triangles, as well right-angled as oblique, that can possibly happen; but there are some other theorems, for right-angled triangles, that are often more convenient in practice than the general ones, the most useful of which is the one that follows:

Case IV. In any right-angled triangle, As radius is to the tangent of either of the acute angles, so is the side adjacent to that angle, to the side opposite to it; and vice versâ.

Or, As radius is to the cotangent of either of the acute angles, so is the side opposite to that angle, to the side adjacent to it; and vice versâ.

It may also be observed, that the sine of either of the acute angles of a right-angled triangle, being equal to the cosine of the other, the latter may be used instead of the former, whenever it renders the operation more simple.

Example I. In any right-angled plane triangle ABC,

Given { BC 324; ∠ B 53° 7′ 48″ } Required the other parts.

By Construction. Make BC = 324, and ∠ B = 53° 7′; then raise the perpendicular CA, meeting BA in A; and the triangle is constructed: in which AB will be found to measure 540, and AC 432; and ∠ A, which is the complement of ∠ B, is 36° 53′.

By Calculation.

:	Rad. or sine	- 90° -		10.0000000
:	Tan. ∠ B	- 53° 7′ 48″		10.1249371
::	Side BC	- 324 -		2.5105450
:	Side AC	- 432 -		2.6354821

:	Sine ∠ A or cos. ∠ B	53° 7′ 48″		9.7781524
:	Side BC	- - 324 -		2.5105450
::	Rad. or sine ∠ C	- 90° -		10.0000000
:	Side AB	- - 540 -		2.7323926

And 90° — 53° 7′ 48″ = 36° 52′ 12″ ∠ A.

We shall now give in a tabular form, (1) The solution of the cases of right-angled plane triangles: and (2) The solution of the cases of oblique plane triangles.

The Solution of the Cases of right-angled plane Triangles, fig. 248.

Case	Given.	Sought.	Proportion.
1	The hypothenu. AC and theangles	The leg BC.	Asthe radius (or the sine of B) is to the hyp. AC; so is the sine of A, to its opposite side BC.
2	The hyp. AC and one leg AB.	The angles.	As, AC : rad. :: AB : sine of C; whose complement gives the angle A.
3	The hyp AC and one leg AB.	The other leg BC.	Let the angles be found by case 2; then, as rad. : AC :: sine of A : BC.
4	The angles and one leg AB.	The hypothenuse AC.	As, sine of C : AB :: rad. (sine of B) : AC.
5	The angles and one leg AB.	The other leg BC.	As, sine of C : AB :: sine of A : BC. Or, rad. : tang. of A :: AB : BC.
6	The two legs AB and BC.	The angles.	As, AB : BC :: rad. : tang. of A, whose complement gives the angle C.
7	The two legs AB and BC.	The hypothenuse AC.	Find the angles, by case 6, and from thence the hyp. AC, by case 4.

The Solution of the Cases of Oblique Plane Triangles, fig. 249.

Case	Given.	Sought.	Proportion.
1	The angles and one side AB.	Either of the other sides,suppose BC.	As, sine of C : AB :: sine of A : BC.
2	Twosides AB, BC, and the ang.Copposite to 1 of them.	Theother angles A and ABC.	As, AB : sine of C :: BC : sine of A; which, added to C, and the sum subtracted from 180°,gives the angle ABC.
3	Twosides AB, BC, and the ang.Copposite to 1 of them.	Theother side AC.	Find the angle ABC, by case 2; then, as sine of A : BC :: sine of ABC : AC.
4	Twosides AB, AC, and the included angle A.	Theother angles C, and ABC.	As, AB + AC : AB — AC :: tang.of the comp.of ½A : tang.of an ang.which added to the said comp. gives the greater ang. C; and subtracted leaves the lesser ABC.
5	Twosides AB, AC, and the included angle A.	Theother side BC.	Find the angles, by case 4, and then BC, by case 1.
6	All the sides.	An angle, suppose A.	Let fall a perpendicular BD, opposite the required angle, and suppose DG = AD; then AC : BC + BA :: BC — BA : CG, which subtracted from AC, and the remainder divided by 2, gives AD; whence A will be found, by case 2 of right angles.

Spherical Trigonometry. Spherical Trigonometry is the art whereby, from three given parts of a spherical triangle, we discover the rest: and, like plane trigonometry, is either right-angled or oblique-angled. But before we give the analogies for the solution of the several cases in either, it will be proper to premise the following theorems:

Theorem I. In all right-angled spherical triangles, the sign of the hypothenuse : radius :: sine of a leg : sine of its opposite angle. And the sine of a leg : radius :: tangent of the other leg : tangent of its opposite angle.

Demonstration. Let AEDAFG (fig. 250,) represent the eighth part of a sphere,where the quadrantal planes EDFG, EDBC, are both perpendicular to the quadrantal plane ADFB: and the quadrantal plane ADGC is perpendicular to the plane EDFG; and the spherical triangle ABC is right-angled at B, where CA is the hypothenuse, and BA, BC, are the legs.

To the arches GF, CB, draw the tangents HF, OB, and the sines GM, CI, on the radii DF, DB; also draw BL the sine of the arch AB, and CK the sine of AC: and then join IK and OL. Now HF, OB, GM, CI, are all perpendicular to the plane ADFB. And HD, GK, OL, lie all in the same plane ADGC. Also FD, IK, BL, lie all in the same plane ADGC. Therefore the right-angled triangles HFD, CIK, ODL, having the equal angles HDF, CKI, OLB, are similar. And CK : DG :: CI : GM; that is, as the sine of the hypothenuse : rad. :: sine of a leg : sine of its opposite angle. For GM is the sine of the arc GF, which measures the angle CAB. Also, LB : DF :: BO : FH: that is, as the sine of a leg : radius :: tangent of the other leg : tangent of its opposite angle. Q. E. D.

Hence it follows, that the sines of the angles of any oblique spherical triangle ACD (fig. 251,) are to one another, directly, as the sines of the opposite sides. Hence it also follows, that in right-angled spherical triangles, having the same perpendicular, the sines of the bases will be to each other, inversely, as the tangents of the angles at the bases.

Theorem II. In any right-angled spherical triangle ABC (fig. 252,) it will be, As radius is to the co-sine of one leg, so is the co-sine of the other leg to the co-sine of the hypothenuse.

Hence, if two right-angled spherical triangles ABC, CBD, (fig. 251,) have the same perpendicular BC, the co-sines of their hypothenuses will be to each other, directly, as the co-sines of their bases.

Theorem III. In any spherical triangle it will be, As radius is to the sine of either angle, so is the co-sine of the adjacent leg to the co-sine of the opposite angle.

Hence, in right-angled spherical triangles, having the same perpendicular, the co-sines of the angles at the base will be to each other, directly, as the sines of the vertical angles.

Theorem IV. In any right-angled spherical triangle it will be, As radius is to the co-sine of the hypothenuse, so is the tangent of either angle to the co-tangent of the other angle.

As the sum of the sines of two unequal arches is to their difference, so is the tangent of half the sum of those arches to the tangent of half their difference: and as the sum of the co-sines is to their difference, so is the co-tangent of half the sum of the arches to the tangent of half the difference of the same arches.

Theorem V. In any spherical triangle ABC (figs. 253 and 254), it will be, As the co-tangent of half the sum to half their difference, so is the co-tangent of half the base to the tangent of the distance (DE) of the perpendicular from the middle of the base.

Since the last proportion, by permutation, becomes co-tang. $\frac{AC + BC}{2}$: co-tang. AE :: tang. $\frac{AC - BC}{2}$: tang. DE, and as the tangents of any two arches are, inversely, as their co-tangents; it follows, therefore, that tang AE : tang. $\frac{AC + BC}{2}$ :: tang. $\frac{AC - BC}{2}$: tang. DE; or, that the tangent of half the base is to the tangent of half the sum of the sides, as the tangent of half the difference of the sides to the tangent of the distance of the perpendicular from the middle of the base.

Theorem VI. In any spherical triangle ABC (fig. 253), it will be, As the co-tangent of half the sum of the angles at the base is to the tangent of half their difference, so is the tangent of half the vertical angle to the tangent of the angle which the perpendicular CD makes with the line CF bisecting the vertical angle.

The following propositions and remarks, concerning spherical triangles (selected and communicated to Dr. Hutton by the reverend Nevil Maskelyne, D. D. astronomer-royal, F. R. S.), will also render the calculation of them perpicuous, and free from ambiguity.

1. A spherical triangle is equilateral, isoscelar, or scalene, according as it has its three angles all equal, or two of them equal, or all three unequal; and vice versa.

2. The greatest side is always opposite the

greatest angle, and the smallest side opposite the smallest angle.

3. Any two sides taken together are greater than the third.

4. If the three angles are all acute, or all right, or all obtuse; the three sides will be, accordingly, all less than 90°, or equal to 90°, or greater than 90°; and vice versa.

5. If from the three angles A, B, C, (fig. 253,) of a triangle ABC, as poles, there are described, upon the surface of the sphere, three arches of a great circle DE, DF, FE, forming by their intersections a new spherical triangle DEF; each side of the new triangle will be the supplement of the angle at its pole; and each angle of the same triangle will be the supplement of the side opposite to it in the triangle ABC.

6. In any triangle ABC, (fig. 255,) or A*b*C, right-angled in A, 1st, The angles at the hypothenuse are always of the same kind as their opposite sides; 2dly, The hypothenuse is less or greater than a quadrant, according as the sides including the right angle are of the same or different kinds; that is to say, according as these same sides are either both acute or both obtuse, or as one is acute and the other obtuse. And vice versa, 1st, The sides including the right angle are always of the same kind as their opposite angles: 2dly, The sides including the right angle will be of the same or different kinds, according as the hypothenuse is less or more than 90°; but one at least of them will be of 90°, if the hypothenuse is so.

The Solution of the Cases of right-angled Spherical Triangles (fig. 252.).

Case.	Given.	Sought.	Solution.
1	The hyp. AC and one angle A	The opposite leg BC	As radius : sine hyp. AC :: sine A : sine BC (by the former part of theor. 1.)
2	The hyp. AC and one angle A	The adjacent leg AB	As radius : co-sine of A :: tang. AC : tang. AB (by the latter part of theor. 1.)
3	The hyp. AC and one angle A	The other angle C	As radius : co-sine of AC :: tang. A : co-tang. C (by theorem 4.)
4	The hyp. AC and one leg AB	The other leg BC	As co-sine AB : radius :: co-sine AC : co-sine BC (by theorem 2.)
5	The hyp. AC and one leg AB	The opposite angle C	As sine AC : radius :: sine AB : sine C (by the former part of theorem 1.)
6	The hyp. AC and one leg AB	The adjacent angle A	As tang. AC : tang. AB :: radius : co-sine A (by theorem 1.)
7	One leg AB and the adjacent angle A	The other leg BC	As radius : sine AB :: tang. A : tang. BC (by theorem 4.)
8	One leg AB and the adjacent angle A	The opposite angle C	As radius : sine A :: co-sine of AB : co-sine of C (by theorem 3.)
9	One leg AB and the adjacent angle A	The hyp. AC	As co-sine of A : radius :: tang. AB : tang AC (by theorem 1.)
10	One leg BC and the opposite angle A	The other leg AB	As tang. A : tang. BC :: radius : sine AB (by theorem 4.)
11	One leg BC and the opposite angle A	The adjacent angle C	As co-sine BC : radius :: co-sine of A : sine C (by theorem 3.)
12	One leg BC and the opposite angle A	The hyp. AC	As sine A : sine BC :: radius : sine AC (by theorem 1.)
13	Both legs AB and BC	The hyp. AC	As radius : co-sine AB :: co-sine BC : co-sine AC (by theorem 2.)
14	Both legs AB and BC	An angle, suppose A	As sine AB : radius :: tang. BC : tang. A (by theorem 4.)
15	Both angles A and C	A leg, suppose AB	As sine A : co-sine C :: radius : co-sine AB (by theorem 3.)
16	Both angles A and C	The hyp. AC	As tang. A : co-tang. C :: radius : co-sine AC (by theorem 4.)

Note, The 10th, 11th, and 12th cases are ambiguous; since it cannot be determined by the data, whether ABC, and AC, are greater or less than 90° each.

In any spherical triangle, the area, or surface inclosed by its three sides upon the surface of the globe, will be found by this proportion:

As 8 right angles, or 720°,
Are to the whole surface of the sphere;
Or, as 2 right angles, or 180°,
To one great circle of the sphere;
So is the excess of the 3 angles above 2 right angles,
To the area of the spherical triangle.

Hence, if a denotes .7854,
$d =$ diam. of the globe, and
$s =$ sum of the 3 angles of the triangle;

then $ad \times \frac{s - 180}{180} =$ area of the spherical triangle.

Hence also, if r denotes the radius of the sphere, and c its circumference; then the area of the triangle will thus be variously expressed; viz., Area $= ad^2 \times \frac{s - 180}{180} = cd \times \frac{s - 180}{720} = cr \times \frac{s - 180}{360}$; or barely $= r \times \overline{s - 180°}$, in square degrees, when the radius r is estimated in degrees; for then the circumference c is $= 360°$.

Farther, because the radius r, of any circle, when estimated in degrees, is $= \frac{180}{3.14159 \text{ \&c.}} = 57.2957795$, the last rule $r \times \overline{s - 180}$, for expressing the area A of the spherical triangle, in square degrees, will be barely

$$A = 57.2957795\, s - 10313.24 =$$
$$= 57\tfrac{50}{169} s - 10313\tfrac{1}{4} \text{ very nearly.}$$

Hence may be found the sums of the three angles in any spherical triangle, having its area A known; for the last equation give the sum $s = \frac{A}{r} + 180 = \frac{A}{57.29 \text{ \&c.}} + 180 = \frac{169A}{9683} + 180$.

So that, for a triangle on the surface of the earth, whose three sides are known; if it is but small, as of a few miles extent, its area may be found from the known length of its sides, considering it as a plane triangle, which gives the value of the quantity A; and then the last rule above will give the value of s, the sum of the three angles; which will serve to prove whether those angles are nearly exact, that have been taken with a very nice instrument, as in large and extensive measurements on the surface of the earth.

Spherical Polygon, is a figure of more than three sides, formed on the surface of a globe by the intersecting arcs of great circles.

The area of any spherical polygon will be found by the following proportion, viz.

As 8 right angles, or 720°,
To the whole surface of the sphere;
Or, as 2 right angles, or 180°,
To a great circle of the sphere;
So is the excess of all the angles above the product of 180, and 2 less than the number of angles,
To the area of the spherical polygon.

That is, putting $n =$ the number of angles,
$s =$ sum of all the angles,
$d =$ diam. of the sphere,
$a = .78539$ &c.;

Then A $= ad^2 \times \frac{s - (n - 2)\, 180}{180} =$ the area of the spherical polygon.

Hence other rules might be found, similar to those for the area of the spherical triangle.

Hence also, the sum s of all the angles of any spherical polygon, is always less than $180n$, but greater than $180\,(n - 2)$; that is, less than n times 2 right angles, but greater than $n - 2$ times 2 right angles.

This will be deemed sufficient on the subject as an introduction to trigonometry, and we can with great satisfaction refer our readers for farther information to Bonnycastle's "Treatise on Plane and Spherical Trigonometry, with their most useful Practical Applications," which is unquestionably the best book on the subject in the English language.

TRIGUERA, a genus of the pentandria monogynia class and order of plants. The corolla is bell-shaped; nect. short; berry four-celled, two seeds in each cell. There are two species, of no note.

TRIHILATÆ, from tres, "three," and hilum, "an external mark on the seed;" the name of the 23d class in Linnæus's Fragments of a Natural Method; consisting of plants

2

with three seeds, which are marked with an external cicatrix or scar, where they are fastened within the fruit. See BOTANY.

TRILIX, a genus of the class and order polyandria monogynia. The calyx is three-leaved; corolla three-petalled; berry five-celled, many seeded. There is one species, a shrub of Carthagena.

TRILLION, in arithmetic, a billion of billions.

TRILLIUM, a genus of the hexandria trigynia class and order of plants. The calyx is three-leaved; corolla three-petalled; berry three-celled. There are three species, hardy perennials.

TRIM *of a ship*, her best posture, proportion of ballast, and hanging of her masts, &c. for sailing. To find the trim of a ship, is to find the best way of making her sail swiftly, or how she will sail best. This is done by easing of her masts and shrouds; some ships sailing much better when they are slack, than when they are taut or fast; but this depends much upon experience and judgment, and the several trials and observations which the commander and other officers may make aboard.

TRINGA, *sandpiper*, a genus of birds belonging to the order of grallæ. The bill is somewhat tapering, and of the length of the head; the nostrils are small; the toes are four in number and divided, the hind toe being frequently raised from the ground. According to Dr. Latham, there are 45 species, of which 18 are British. We shall describe some of the most remarkable.

1. Vanellus, lapwing, or tewit, is distinguished by having the bill, crown of the head, crest, and throat, of a black colour; there is also a black line under each eye; the back is of a purplish green; the wings and tail are black and white, and the legs red; the weight is eight ounces, and the length 13 inches. It lays four eggs, making a slight nest with a few bents. The eggs have an olive cast, and are spotted with black. The young, as soon as hatched, run like chickens. The parents show remarkable solicitude for them, flying with great anxiety and clamour near them, striking at either men or dogs that approach, and often fluttering along the ground like a wounded bird, to a considerable distance from their nest, to delude their pursuers; and to aid the deceit, they become more clamorous when most remote from it. The eggs are held in great esteem for their delicacy, and are sold by the London poulterers for 4 or 5 shillings the dozen. In winter, lapwings join in vast flocks; but at that season are very wild: their flesh is very good, their food being insects and worms. During October and November, they are taken in the fens in nets, in the same manner that ruffs are; but are not preserved for fattening, being killed as soon as caught.

2. Pugnax. The male of this species is called ruff, and the female reeve. The name ruff is given to the males because they are furnished with very long feathers, standing out in a remarkable manner, not unlike the ruff worn by our ancestors. The ruff is of as many different colours as there are males; but in general it is barred with black; the weight is six or seven ounces; the length one foot. The female, or reeve, has no ruff; the common colour is brown; the feathers are edged with a very pale colour; the breast and belly white. Its weight is about four ounces. See Plate Nat. Hist.

These birds appear in the fens in the earliest spring, and disappear about Michaelmas. The reeve lays four eggs in a tuft of grass, the first week in May, and sit about a month. The eggs are white, marked with large rusty spots. Fowlers avoid in general the taking of the females; not only because they are smaller than the males, but that they may be left to breed.

Soon after their arrival, the males begin to hill; that is, to collect on some dry bank near a splash of water, in expectation of the females who resort to them. Each male keeps possession of a small piece of ground, which it runs round till the grass is worn quite away, and nothing but a naked circle is left. When a female lights, the ruffs immediately fall to fighting. It is a vulgar error, that ruffs must be fed in the dark, lest they should destroy each other by fighting on admission of light. The truth is, every bird takes its stand in the room as it would in the open fen. If another invades its circle, an attack is made, and a battle ensues. They make use of the same action in fighting as a cock, place their bills to the ground and spread their ruffs. Mr. Pennant says he has set a whole roomful a fighting, by making them move their stations; and, after quitting the place, by peeping through a crevice, seen them resume their circles, and grow pacific.

When a fowler discovers one of those hills, he places his net over night, which is of the same kind as those that are called clap or day nets; only it is generally single, and is about 14 yards long and four broad. The fowler resorts to his stand at day-break, at the distance of one, two, three, or four hundred yards from the nets, according to the time of the season; for the later it is, the shyer the birds grow. He then makes his first pull, taking such birds as he finds within reach; after that he places his stuffed birds or stales, to entice those that are continually traversing the fen. When the stales are set, seldom more than two or three are taken at a time. A fowler will take forty or fifty dozen in a season. These birds are found in Lincolnshire, the isle of Ely, and in the East Riding of York. They visit a place called Martin-Mere, in Lancashire, the latter end of March or beginning of April; but do not continue there above three weeks; where they are taken in nets, and fattened for the table with bread and milk, hempseed, and sometimes boiled wheat; but if expedition is required, sugar is added, which will make them in a fortnight's time a lump of fat: they then sell for two shillings or half a crown a-piece. They are dressed like the woodcock, with their intestines: and when killed at the critical time, say the epicures, are the most delicious of all morsels.

3. Canutus, or knot, has the forehead, chin, and lower part of the neck, brown, inclining to ash-colour; the back and scapulars deep brown, edged with ash-colour; the coverts of the wings white, the edges of the lower order deeply so, forming a white bar; the breast, sides, and belly, white, the two first streaked with brown; the coverts of the tail marked with white and dusky spots alternately; the tail ash-coloured, the outmost feather on each side white; the legs of a blueish grey; and the toes, as a special mark, divided to the very bottom; the weight four ounces and a half. These birds, when fattened, are preferred by some to the ruffs themselves. They are taken in great numbers on the coasts of Lincolnshire, in nets such as are employed in taking ruffs; with two or three dozen of stales of wood painted like the birds, placed within: 14 dozens have been taken at once. Their season is from the beginning of August to that of November. They disappear with the first frosts. Camden says, they derive their name from king Canute, Knute, or Knout, as he is sometimes called; probably because they were a favourite dish with that monarch. We know that he kept the feast of the purification of the Virgin Mary with great pomp and magnificence at Ely; and this being one of the fen birds, it is not unlikely that he met with it there.

4. The hypoleucos, or common sandpiper, except in pairing time, is a solitary bird. It is never found near the sea, but frequents rivers, lakes, and other fresh waters. Its head is brown, streaked with downward black lines; the neck, an obscure ash-colour; the back and coverts of the wings, brown, mixed with a glossy green, elegantly marked with transverse dusky lines; the breast and belly are of a pure white; the quill-feathers and the middle feathers of the tail are brown; the legs of a dull pale green.

5. The alpina, or dunling sandpiper, is at once distinguished from the others by the singularity of its colours. The back, head, and upper part of the neck, are ferruginous, marked with large black spots; the lower part of the neck white, marked with short dusky streaks; the coverts of the wings ash-colour; the belly white, marked with large black spots, or with a black crescent pointing towards the thighs; the tail is ash-coloured; legs black; toes divided to their origin. In size it is superior to that of a lark. These birds are found on our sea-coasts; but may be reckoned among the more rare kinds. They lay four eggs of a dirty white colour, blotched with brown round the thicker end, and marked with a few small spots of the same colour on the smaller end. They are common on the Yorkshire coasts, and esteemed a great delicacy.

6. The cinclus, purre, or stint, is in length seven and a half inches; the head and hind part of the neck are ash-coloured, marked with dusky lines; a white stroke divides the bill and eyes; the back is of a brownish ash-colour; the breast and belly white; the coverts of the wings and tail a dark brown, edged with light ash-colour or white; the upper part of the quill-feathers dusky, the lower white; the legs of a dusky green; the toes divided to their origin. The bill an inch and a half long, slender and black; irides dusky. These birds come in large flocks on our sea-coasts in winter.

TRINITARIANS, those who are orthodox and believe in the trinity: those who do not believe therein, being called anti-trinitarians.

TRINITY-HOUSE, a kind of college at Deptford, belonging to a company or corporation of seamen, who, by the king's charter, have power to take cognizance of those persons who destroy sea-marks, and to get reparation of such damages; and to take care of other things belonging to navigation. At present, many gentry and some nobility are members of that community.

The master, wardens, and assistants of the trinity-house, may set up beacons, and marks for the sea, in such places near the coasts or forelands, as to them shall seem meet. By a statute of queen Elizabeth, no steeple, trees, or other things standing as sea-marks, shall be taken away or cut down, upon pain that every person guilty of such offence, shall forfeit 100*l.* and if the person offending is not possessed of the value, he shall be deemed convict of outlawry.

TRINITY, *fraternity of*, a religious society instituted at Rome by St. Philip Neri, in 1548. These religious were appointed to take care of the pilgrims who came to visit the tombs of St. Peter and St. Paul. The society originally consisted of only 15 religious, who assembled on the first Sunday of every month, in the church of St. Saviour del Campo, to hear the exhortations of the founder; after whose death pope Paul IV. gave the fraternity the church of St. Benedict, near which they have since built a large hospital, for the reception of pilgrims. The fraternity is one of the most considerable in Rome, and most of the nobility of both sexes have been members of it.

TRINOMIAL, or TRINOMIAL ROOT, in mathematics, is a root consisting of three parts connected together by the signs + or —, as $x+y+z$, or $a+b-c$. See BINOMIAL and ROOT.

TRIO, in music, a part of a concert wherein three persons sing; or more properly, a musical composition consisting of three parts. Trios are the finest kinds of composition, and these are what please most in concerts.

TRIOPTERIS, a genus of the decandria trigynia class of plants, the corolla whereof consists of six oval, erectopatulous, equal and permanent petals, surrounded by three others, smaller than themselves, but equal to one another; there is no pericarpium; the seeds are three, erect, and carinulated at the back, each of them has externally at its base an ala, and at its apex two; these alæ are what in the flowering state of the plant appear to be petals, but they are not truly such. There are two species, shrubs of the West Indies.

TRIOSTEUM, a genus of the pentandria monogynia class and order of plants. The calyx is the length of the corolla; corolla one-petalled, almost equal; berry three-celled, unequal; seeds solitary. There are three species, herbs of North America. The roots are said to be emetic.

TRIPLARIS, a genus of the dioecia dodecandria class and order. The calyx is very large, three or six-parted; corolla three-petalled; nect. three-sided. There are two species, trees of South America.

TRIPLE, or TRIPLE TIME, in music, a time consisting of three measures in a bar; the two first of which are beaten with the hand or foot down, and the third marked by its elevation. There were formerly in use no less than six different triple measures: first, that of three breves in a bar, denoted by the figure 3; secondly, that of three semibreves in a bar, the sign of which was $\frac{3}{1}$; thirdly, that of three minims in a bar, marked by $\frac{3}{2}$; fourthly, that of three crotchets in a bar, implied by $\frac{3}{4}$; fifthly, that of three quavers in a bar, signified by $\frac{3}{8}$; and, sixthly, that of three semiquavers in a bar, expressed by $\frac{3}{16}$. But at present we only employ three different triples; that of three minims, that of three crotchets, and that of three quavers. The reader being informed that the semibreve (which is now the longest note in common use, and therefore made the common standard of reckoning), is equal in duration to two minims, or to four crotchets, or eight quavers, will readily comprehend the propriety of announcing these different measures by the above figures; and will perceive that, to indicate a time of three minims in a bar (*i. e.* three halves, or second parts, of a semibreve), no method more concise or simple could be adopted, than that of placing at the beginning of the movement the figures $\frac{3}{2}$; for a time of three crotchets (*i. e.* three-fourth parts of a semibreve), the figures $\frac{3}{4}$; and for a time of three quavers (*i. e.* three-eights of a semibreve), the figures $\frac{3}{8}$.

The old musicians considered the triple, or three-timed measure, as superior to the binary, or two-timed, and for that reason called it the perfect time.

TRIPLE PROGRESSION, an expression in old music, implying a series of perfect fifths. A progression of sounds thus explained by theorists: let any sound be represented by unity, or the number 1; and as the third part of a string has been found to produce the twelfth, or octave of the fifth above the whole string, a series of fifths may be represented by a triple geometric progression of numbers, continually multiplied by 3; as 1, 3, 9, 27, 81, 243, 729; and these terms may be equally supposed to represent twelfths, or fifths, either ascending or descending: for whether we divide by 3, or multiply by 3, the terms will either way be in the proportion of a twelfth, or octave to the fifth.

TRIPLICATE RATIO, the ratio which cubes bear to one another.

This ratio is to be distinguished from triple ratio, and may be thus conceived. In the geometrical proportions 2, 4, 8, 16, 32, as the ratio of the first term (2) is to the third (8) duplicate of the first to the second, or of the second to the third, so the ratio of the first to the fourth is said to be triplicate of the ratio of the first to the second, or of that of the second to the third, or of that of the third to the fourth, as being compounded of three equal ratios. See RATIO.

TRIPOLI, a mineral found sometimes in an earthy form, but more generally indurated. Its texture is earthy. Specific gravity 2 to 2.5. It absorbs water, feels harsh and dry. Scarcely adheres to the tongue; takes no polish from the nail; does not stain the fingers. Colour generally pale yellowish grey; also different kinds of yellow, brown, and white. According to Klaproth, a species of this mineral contained

66.5	silica
7.0	alumina
2.5	oxide of iron
1.5	magnesia
1.25	lime
19.0	air
97.75.	

TRIPSACUM, a genus of the monœcia triandria class and order of plants. The male calyx is a glume, four-flowered; corolla, glume membranaceous; female calyx, glume perforated sinuses; corolla, glume two-valved; styles two; seed one. There are two species, grasses of the West Indies.

TRISECTION, or TRISSECTION, the dividing a thing into three. The term is chiefly used in geometry, for the division of an angle into three equal parts. The trisection of an angle geometrically, is one of those great problems whose solution has been so much sought by mathematicians for these two thousand years, being in this respect on a footing with the quadrature of the circle, and the duplicature of the cube angle.

The cubic equation by which the problem of trisection is resolved, is as follows: Let c denote the chord of a given arc, or angle, and x the cord of the 3d part of the same, to the radius 1; then is $x^3 - 3x = -c$,
by the resolution of which cubic equation is found the value of x, or the chord of the 3d part of the given arc or angle, whose chord is c; and the resolution of this equation, by Cardan's rule, gives the chord

$$x = \sqrt[3]{\frac{-c+\sqrt{c^2-4}}{2}} + \frac{1}{\sqrt[3]{\frac{-c+\sqrt{c^2-4}}{2}}}$$

$$\text{or } x = \sqrt[3]{\frac{-c+\sqrt{c^2-4}}{2}} + \sqrt[3]{\frac{-c-\sqrt{c^2-4}}{2}}$$

TRISETOUS, in entomology, three-bristled, applied chiefly to the tail of insects, as in the ephemera.

TRISPAST, in mechanics, a machine with three pullies, or an assemblage of three pullies for raising of great weights.

TRITICUM, *wheat*, a genus of plants of the class triandria, and order digynia, and in the natural system ranging under the fourth order, gramina. The calyx is bivalve, solitary, and generally containing three florets; the corolla is bivalve, one valve being bluntish, the other acute. There are 19 species, the æstivum, summer or spring wheat; hybernum, winter, Lammas, or common wheat; compositum, turginum, or cone wheat; polonicum, or Polish wheat; spelta, or spelt wheat; monococcum, or one-grained wheat; prostratum, or trailing wheat-grass; pumilum, or dwarf wheat-grass: junceum, or rush wheat-grass; repens, or couch-grass; tenellum, or tender wheat-grass; maritimum, or sea wheat-grass; unilaterale, or spiked sea-wheat; unioloides, or linear-spiked wheat-grass; distichum, loliaceum, caninum, hispanicum. Of what country the first six species are natives, cannot now be determined: the prostratum is a native of Siberia; the junceum, repens, unilaterale, and maritimum, are natives of Britain; the tenellum is a native of Spain, and the unioloides is a native of Italy. It may also be observed, that the first nine are annuals, the rest are perennials.

Linnæus comprehends the different kinds of wheat cultivated at present under six species; but cultivation has produced a great many varieties from these.

1. Triticum æstivum, or spring-wheat, has four flowers in a calyx, three of which mostly bear grain. The calyces stand pretty distant from each other, on both sides a flat smooth receptacle. The leaves of the calyx are keel-shaped, smooth, and they terminate with a short arista. The glumes of the flowers are smooth and bellying, and the outer leaf of three of the glumes in every calyx is terminated by a long arista, but the three inner ones are beardless. The grain is rather longer and thinner than the common wheat. It is supposed to be a native of some part of Tartary. The farmers call it spring-wheat, because it will come to the sickle with the common wheat, though it should be sown in February or March. The varieties of it are: triticum æstivum spica et grana rubente. Spring wheat, with a red spike and grain. Triticum æstivum rubrum, spica alba. Red spring wheat, with a white spike. Triticum æstivum, spica et grana alba. Spring wheat, with a white spike and grain.

2. Triticum hybernum, winter or common wheat, has also four flowers in a calyx, three of which are mostly productive. The calyces stand on each side a smooth flat receptacle, as in the former species, but they are not quite so far asunder. The leaves of the calyx are bellying, and so smooth that they appear as if polished, but they have no arista. The glumes of the flowers too are smooth, and the outer ones, near the top of the spike, are often tipped with short aristæ. The grain is rather plumper than the former, and is the sort most generally sown in England; whence the name of common wheat. Its varieties are: triticum hybernum, spica et grana rubente. Common wheat, with a red spike and grain. Triticum hybernum rubrum, spica alba. Common red wheat, with a white spike. Triticum hybernum, spica et grana alba. Common wheat, with a white spike and grain.

3. Triticum turgidum, thick-spiked or cone-wheat. It is easily distinguished from either of the former: for though it has four flowers in a calyx, after the manner of them, yet the whole calyx and the edges of the glumes are covered with soft hairs. The calyces too stand thicker on the receptacle, and make the spike appear more turgid. Some of the outer glumes near the top of the spike are terminated by short aristæ, like those of the common wheat. The grain is shorter, plumper, and more convex on the back than either of the former species. Its varieties are numerous, and have various appellations in different counties, owing to the great affinity of several of them. Those most easily to be distinguished are: triticum turgidum conicum album. White cone wheat. Triticum turgidum conicum rubrum. Red cone wheat. Triticum turgidum aristiferum. Bearded cone wheat. Triticum turgidum spica multiplici. Cone wheat, with many ears. The third variety is what the farmers call clog wheat, square wheat, and rivets. The grain of this is remarkably convex on one side, and when ripe the awns generally break in pieces and fall off. This sort is very productive, but it yields an inferior flour to that of the former two species.

4. Triticum Polonicum, or Polish wheat, has some resemblance to the turgidum, but both grain and spike are longer. The calyx contains only two flowers, and the glumes are furnished with very long aristæ; the teeth of the midrib are bearded. As this sort is seldom sown in England, there is no telling what varieties it produces.

5. Triticum spelta, spelt or German wheat. At first view this has a great resemblance to barley, but it has no involucrum. The calyx is truncated; that is, it appears as if the ends were snipped off, and it contains four flowers, two of which are hermaphrodite, and the glumes bearded, but the intermediate ones are neuter. There are two rows of grain as in barley, but they are shaped like wheat. It is much cultivated in France, Germany, and Italy.

6. Triticum monococcum, St. Peter's corn, or one-grained wheat, has three flowers in each calyx alternately bearded, and the middle one neuter. The spike is shining, and has two rows of grain in the manner of barley. Where it grows naturally is not known, but it is cultivated in Germany; and in conjunction with spelt wheat is there made into bread, which is coarse, and not so nourishing as that made of common wheat. Malt made of any of our wheats is often put into beer, and a small quantity of it will give a large brewing a fine brown transparent tincture.

Of the perennial kinds, or wheat grasses, the repens, or couch grass is unfortunately too well known to the gardener and husbandman; the others are of little note.

The respectable president of the Royal Society, whose attention is constantly directed to those branches of knowledge which are most practically useful, has published some remarks on the blight in corn in the year 1805; and we feel ourselves discharging a duty in making them as generally known as our circulation extends.

He begins by observing that the blight in corn is occasioned by the growth of a minute parasitic fungus or mushroom on the leaves, stems, and glumes of the living plant. Felice Fontana published, in the year 1767, an elaborate account of this mischievous weed, with microscopic figures, which give a tolerable idea of its form; more modern botanists have given figures both of corn and of grass affected by it, but have not used high magnifying powers in their researches.

He adds, "agriculturists do not appear to have paid, on this head, sufficient attention to the discoveries of their fellow-labourers in the field of nature; for though scarcely any English writer of note on the subject of rural economy, has failed to state his opinion of the origin of this evil, no one of them has yet attributed it to the real cause, unless Mr. Kirby's excellent papers on some diseases of corn, published in the Taansactions of the Linnæan Society, are considered as agricultural essays.

It is necessary to premise, that the striped appearance of the surface of a straw which may be seen with a common magnifying glass, is caused by alternate longitudinal partitions of the bark, the one imperforate, and the other furnished with one or two rows of pores or mouths, shut in dry, open in wet weather, and well calculated to imbibe fluid whenever the straw is damp.

By these pores, which exist also on the leaves and glumes, it is presumed that the seeds of the fungus gain admission, and at the bottom of the hollows to which they lead, (see Plate II. fig. 1, 2), they germinate and push their minute roots, no doubt (though these have not yet been traced) into the cellular texture beyond the bark, where they draw their nourishment, by intercepting the sap that was intended by nature for the nutriment of the grain; the corn of course becomes shrivelled in proportion as the fungi are more or less numerous on the plant; and as the kernel only is abstracted from the grain, while the cortical part remains undiminished, the propo tion of flour or bran in blighted corn, is always reduced in the same degree as the corn is made light. Some corn of this year's crop will not yield a stone of flour from a sack of wheat; and it is not impossible that in some cases the corn has been so completely robbed of its flour by the fungus, that if the proprietor should choose to incur the expence of threshing and grinding it, bran would be the produce, with scarcely an atom of flour for each grain.

Every species of corn, properly so called, is subject to the blight; but it is observable that spring corn is less damaged by it than winter, and rye less than wheat, probably because it is ripe and cut down before the fungus has had time to increase in any large degree. Tull says that "white cone, or bearded wheat, which hath its straw like a rush full of pith, is less subject to blight than Lammas wheat, which ripens a week later."

The spring wheat of Lincolnshire was not in the least shrivelled this year, though the straw was in some degree affected: the millers allowed that it was the best sample brought to market. Barley was in some places considerably spotted, but as the whole of the stem of that grain is naturally enveloped in the hose or basis of the leaf, the fungus can in no case gain admittance to the straw; it is, however, to be observed that barley rises from the flail lighter this year than was expected from the appearance of the crop when gathered in.

It seems probable that the leaf is first infected in the spring or early in the summer, before the corn shoots up into straw, and that the fungus is then of an orange colour; after the straw has become yellow, the fungus assumes a deep chocolate brown: each individual is so small that every pore on a straw will produce from 20 to 40 fungi, as may be seen in the plates, and every one of these will no doubt produce at least 100 seeds; if then one of these seeds tillows out into the number of plants that appear at the bottom of a pore in Plate II. fig. 1, 2, how incalculably large must the increase be! A few diseased plants scattered over a field must very speedily infect a whole neighbourhood, for the seeds of fungi are not much heavier than air, as every one who has trod upon a ripe puff-ball must have observed by seeing the dust, among which is its seed, rise up and float on before him.

How long it is before this fungus arrives at puberty, and scatters its seeds in the wind, can only be guessed at by the analogy of others; probably the period of a generation is short, possibly not more than a week in a hot season: if so, how frequently in the latter end of the summer must the air be loaded with this animated dust, ready, whenever a gentle breeze, accompanied with humidity, shall give the signal to intrude itself into the pores of thousands of acres of corn. Providence, however, careful of the creatures it has created, has benevolently provided against the too extensive multiplication of any species of being; was it otherwise, the minute plants and animals, enemies against which man has the fewest means of defence, would increase to an inordinate extent: this, however, can in no case happen, unless many predisposing causes afford their combined assistance. But for this wise and beneficent provision, the plague of slugs, the plague of mice, the plagues of grubs, wire-worms, chafers, and many other creatures whose power of multiplying is countless as the sands of the sea, would, long before this time, have driven mankind, and all the larger animals, from the face of the earth.

Though all old persons who have concerned themselves in agriculture, remember the blight in corn many years, yet some have supposed that of late years it has materially increased; this, however, does not seem to be the case. Tull, in his Horsehoeing Husbandry, page 74, tells us, that the year 1725 "was a year of blight, the like of which was never before heard of, and which he hopes may never happen again;" yet the average price of wheat in the year 1726, when the harvest of 1725 was at market, was only 36*s*. 4*d*. and the average of the five years of which it makes the first, 37*s*. 7*d*.--1797 was also a year of great blight; the price of wheat in 1798 was 49*s*. 1*d*. and the average of the five years, from 1795 to 1799, 63*s*. 5*d*.

The climate of the British isles is not the only one that is liable to the blight in corn. It happens occasionally in every part of Europe, and probably in all countries where corn is grown. Italy is very subject to it, and the last harvest of Sicily has been materially hurt by it. Specimens received from the colony of New South Wales, shew that considerable mischief was done to the wheat crop there in the year 1803, by a parasitic plant, very similar to the English one.

It has been long admitted by farmers, though scarcely credited by botanists, that wheat in the neighbourhood of a barberry bush seldom escapes the blight. The village of Rollesby in Norfolk, where barberries abound, and wheat seldom succeeds, is called by the opprobrious appellation of mildew Rollesby. Some observing men have of late attributed this very perplexing effect to the farina of the flowers of the barberry, which is in truth yellow, and resembles in some degree the appearance of the rust, or what is presumed to be the blight in its early state.

It is, however, notorious to all botanical observers, that the leaves of the barberry are very subject to the attack of a yellow parasitic fungus, larger, but otherwise much resembling the rust in corn.

Is it not more than possible that the parasitic fungus of the barberry and that of wheat, are one and the same species, and that the seed is transferred from the barberry to the corn? Misletoe, the parasitic plant with which we are the best acquainted, delights most to grow on the apple and hawthorn, but it flourishes occasionally on trees widely differing in their nature from both of these. In the Home Park, at Windsor, misletoe may be seen in abundance on the lime trees planted there in avenues. If this conjecture is founded, another year will not pass without its being confirmed by the observations of inquisitive and sagacious farmers.

It would be presumptuous to offer any remedy for a malady, the progress of which is so little understood; conjectures, however, founded on the origin here assigned to it, may be hazarded without offence.

It is believed to begin early in the spring, and first to appear on the leaves of wheat in the form of rust, or orange-coloured powder; at this season, the fungus will, in all probability, require as many weeks for its progress from infancy to puberty, as it does days during the heats of autumn; but a very few plants of wheat, thus infected, are quite sufficient if the fungus is permitted to ripen its seed, to spread the malady over a field, or indeed over a whole parish.

The chocolate-coloured blight is little observed till the corn is approaching very nearly to ripeness; it appears then in the field in spots, which increase very rapidly in size, and are in calm weather somewhat circular, as if the disease took its origin from a central position.

May it not happen, then, that the fungus is brought into the field in a few stalks of infected straw, uncorrupted, among the mass of dung laid in the ground at the time of sowing? It must be confessed, however, that the clover lays, on which no dung from the yard was used, were as much infected last autumn as the manured crops. The immense multiplication of the disease in the last season, seems, however, to account for this; as the air was no doubt frequently charged with seed for miles together, and deposited it indiscriminately on all sorts of crops.

It cannot, however, be an expensive precaution to search diligently in the spring for young plants of wheat infected with the disease, and carefully to extirpate them, as well as all grasses, for several are subject to this or a similar malady, which have the appearance of orange-coloured or of black stripes on their leaves, or on their straw; and if experience shall prove that uncorrupted straw can carry the disease with it into the field, it will cost the farmer but little precaution to prevent any mixture of fresh straw from being carried out with his rotten dung to the wheat field.

In a year like the present, that offers so fair an opportunity, it will be useful to observe attentively whether cattle in the straw-yard thrive better or worse on blighted than on healthy straw. That blighted straw, retaining on it the fungi that have robbed the corn of its flour, has in it more nutritious matter than clean straw which has yielded a crop of plump grain, cannot be doubted; the question is, whether this nutriment in the form of fungi does, or can be made to agree as well with the stomachs of the animals that consume it, as it would do in that of straw and corn.

It cannot be improper in this place to remark, that although the seeds of wheat are rendered, by the exhausting power of the fungus, so lean and shrivelled, that scarcely any flower fit for the manufacture of bread can be obtained by grinding them, these very seeds will, except, perhaps, in the very worst cases, answer the purpose of seed-corn as well as the fairest and plumpest sample that can be obtained, and, in some respects, better; for as a bushel of much blighted corn will contain one-third, at least, more grains in number than a bushel of plump corn, three bushels of such corn will go as far in sowing land, as four bushels of large grain.

The use of the flour of corn in furthering the process of vegetation, is to nourish the minute plant from the time of its developement till its roots are able to attract food from the manured earth; for this purpose, one-tenth of the contents of a grain of good wheat is more than sufficient. The quantity of flour in wheat has been increased by culture and management, calculated to improve its qualities for the benefit of mankind, in the same proportion as the pulp of apples and pears has been increased, by the same means, above what is found on the wildings and crabs in the hedges.

It is customary to set aside or to purchase for seed-corn, the boldest and plumpest samples that can be obtained; that is, those that contain the most flour; but this is an unnecessary waste of human subsistence; the smallest grains, such as are sifted out before the wheat is carried to market, and either consumed in the farmer's family, or given to his poultry, will be found by experience to answer the purpose of propagating the sort whence they sprung, as effectually as the largest.

Every ear of wheat is composed of a number of cups placed alternately on each side of the straw; the lower ones contain, according to circumstances, three or four grains, nearly equal in size, but towards the top of the ear, where the quantity of nutriment is diminished by the supply of those cups that are nearer the root, the third or fourth grain in a cup is frequently defrauded of its proportion, and becomes shrivelled and small. These small grains, which are rejected by the miller, because they do not contain flour enough for his purpose, have, nevertheless, an ample abundance for all purposes of vegetation, and as fully partake of the sap, (or blood, as we should call it in animals,) of the kind which produced them, as the fairest and fullest grain that can be obtained from the bottoms of the lower cups by the wasteful process of beating the sheaves.

TRITOMA, a genus of insects of the coleoptera order. The generic character is, antennæ clavate, the club perfoliate; lip emarginate; anterior feelers hatchet-shaped; shells as long as the body. There are ten species,

TRITON, a genus of vermes mollusca. The generic character is, body long; mouth with an involute spiral proboscis; tentacula, or arms, twelve, viz. six on each side, divided nearly to the base, the end ones cheliferous. There is only a single species, viz. the littoreous, which is found in Italy, in various cavities of submarine rocks, and may be seen in many species of the lepas, particularly in the anatafera.

TRITURATION. See Pharmacy.

TRIUMFETTA, a genus of the dodecandria monogynia class of plants, the corolla of which consists of five linear, erect, obtuse petals, hollowed, and bent backwards; the point is prominent below the apex; the fruit is a globose capsule, every where surrounded with hooked prickles, and contains four cells; the seeds are two, convex on one side and angular on the other; but only one of the two seeds of each cell usually ripens. There are 11 species, chiefly shrubs of the West Indies.

TRIXIS, a genus of the syngenesia polygamia class and order of plants. The corollæ of the ray are trifid, seeds hairy at the top, without any down; recept. chaffy. There are three species, herbs of the West Indies.

TROCHAIC VERSE, in the Latin poetry, a kind of verse, so called because the trochees chiefly prevail, as the iambus does in the iambic. It generally consists of seven feet and a syllable; the odd feet, for the most part, consist of trochees, though a tribrachys is sometimes admitted, except in the seventh foot; these two feet are likewise used in the other places, as is also the spondæus, dactylus, and anapæstus. The following is an example:

1 2 3 4 5
Solus | aut rex | aut po | eta | non quot |
6 7 ½
annis | nasci | tur.

TROCHANTER. See ANATOMY.

TROCHE. See PHARMACY.

TROCHEE, in the Greek and Latin poetry, a foot consisting of two syllables, the first long and the second short, as in the words mūsă and sērvăt.

TROCHILUS, *humming-bird*, a genus of birds belonging to the order of picæ. The rostrum is subulate, filiform, and longer than the head, the apex being tubular; the upper mandible sheaths the lower. The tongue is filiform and tubulous, the two threads coalescing; the feet are slender and fit for walking; the tail has ten feathers. There are 65 species, none of which are natives of Britain. They are all remarkable for the beauty of their colours, and most of them for the smallness of their size, though some are eight or nine inches in length. They are divided into two families, viz. those with crooked bills, and those with straight bills. See Plate Nat. Hist. fig. 408. Of these we shall describe the four following species:

1. The exilis, or little humming-bird, has a crooked beak, is an inch and a half in length; frequently weighing less than 50 grains. The bill is black, and half an inch in length; the body greenish-brown, with a red shining, inimitable gloss; the head is crested with a small tuft, green at bottom, but of a sparkling gold colour at top; quills and tail fine black. It is a native of Guiana; and the velocity of it in flying is so great, that the eye can scarcely keep pace with its motion.

2. The moschitus, or ruby-necked humming-bird, according to Marcgrave, is the most beautiful of the whole genus. Its length is three inches four lines; the bill straight, eight lines long, and blackish; the top of the head and hind part of the neck are as bright as a ruby, and of the same colour: the upper parts of the body are brown, with a faint mixture of green and gold; the throat and fore-part of the neck are the colour of the most brilliant topaz; the belly, sides, and thighs, are brown; but on the lower part of the belly, on each side, is a spot of white; the tail is rufous purple, inclining to violet at the ends; the two middle feathers are shortest; the legs and claws blackish. The female has only a dash of golden or topaz on the breast and fore-part of the neck; the rest of the under parts are greyish-white. This species is found in Brasil, Curassoa, Guiana, and Surinam. See Plate Nat. Hist. fig. 409.

3. The minimus, or least humming-bird, is exceeded, both in weight and dimensions, by several species of bees. The total length is one inch and a quarter; and when killed, weighs no more, according to Sir Hans Sloane, than 20 grains. The bill is straight and black, three lines and a half in length; the upper parts of the head and body are of a greenish gilded brown, in some lights appearing reddish; the under parts are greyish-white; the wings are violet-brown; the tail of a bluish-black, with a gloss of polished metal; but the outer feather, except one on each side, is grey from the middle to the tip, and the outer one wholly grey; legs and claws brown. The female is less than the male; the whole upper side of a dirty brown, with a slight gloss of green; the under parts of a dirty-white. These birds are found in various parts of South America and the adjacent islands.

4. Superciliosus, white shaft, or supercilious humming-bird, has a bill twenty lines long; the feathers of the tail next the two long shafts are also the longest, and the lateral ones continually decrease to the two outermost, which are the shortest, and this gives the tail a pyramidal shape; its quills have a goldgloss on a grey and blackish ground, with a whitish edge at the point, and the two shafts are white through the whole projecting portions; all the upper side of the back and head gold-colour; the wing violet-brown; and the under side of the body white-grey.

These birds subsist on the nectar or sweet juice of flowers: they frequent those most which have a long tube, particularly the impatiens noli me tangere, the monarda with crimson flowers, and those of the convolvulus tribe. They never settle on the flower during the action of extracting the juice, but flutter continually like bees, moving their wings very quick, and making a humming noise; whence their name. They are not very shy, suffering people to come within a foot or two of the place where they are, but when approached nearer, fly off like an arrow out of a bow. They often meet and fight for the right to a flower, and this all on the wing. In this state they often come into rooms where the windows stand open, fight a little, and go out again. When they come to a flower which is juiceless, or on the point of withering, they pluck it off as if in anger, by which means the ground is often quite covered with them. When they fly against each other, they have, besides the humming, a sort of chirping noise, like a sparrow or chicken. They do not feed on insects or fruit; nor can they be kept long in cages, though they have been preserved alive for several weeks together, by feeding them with water in which sugar had been dissolved.

This bird most frequently builds in the middle of a branch of a tree, and the nest is so small that it cannot be seen by a person who stands on the ground; any one therefore desirous of seeing it must get up to the branch, that he may view it from above: it is for this reason that the nests are not more frequently found. The nest is of course very small, and quite round; the outside, for the most part composed of green moss, common on old pales and trees; the inside of soft down, mostly collected from the leaves of the great mullein, or the silk grass; but sometimes they vary the texture, making use of flax, hemp, hairs, and other soft materials: they lay two eggs of the size of a pea, which are white, and not bigger at one end than the other.

The above account of the manners will in general suit all the birds of this genus; for as their tongues are made for suction, it is by this method alone that they can gain nourishment: no wonder, therefore, they can scarcely be kept alive by human art. Captain Davies, however, kept these birds alive for four months by the following method: He made an exact imitation of some of the tubular flowers with paper, fastened round a tobacco-pipe, and painted them of a proper colour; these were placed in the order of nature, in the cage wherein these little creatures were confined; the bottoms of the tubes were filled with a mixture of brown sugar and water as often as emptied; and he had the pleasure of seeing them perform every action, for they soon grew familar, and took the nourishment in the same manner as when ranging at large, though close under his eye.

TROCHOID. See CYCLOID.

TROCHUS, a genus of vermes testacea: the generic character is, animal a limax; shell univalve, spiral, more or less conic; aperture somewhat angular or rounded; the upper side transverse and contracted; pillar placed obliquely. See Plate Nat. Hist. fig. 410. There are about 120 species.

TROGON, or *curucui*, a genus of birds of the order picæ. The generic character is, bill shorter than the head, sharp-edged, hooked, the mandibles serrate, at the edge; feet formed for climbing. There are nine species. They all inhabit warm countries, are solitary, and live in damp unfrequented woods, building on the lower branches: their flight is short, and they feed on insects: body long; nostrils covered with bristles; feet short, woolly; tail very long, consisting of 12 feathers.

TROLLIUS, *globe-flower*, in botany, a genus of plants of the class polyandria, and order polygynia, and in the natural system ranging under the 26th order, multisiliquæ. The calyx is wanting; there are about 14 petals; the capsules are very numerous, ovate, and many seeded. There are two species, the asiaticus and europæus; the latter of which is a British plant. The europæus, or European globe-flower, has its corollets connivent, and from nine to sixteen nectaria, of the length of the stamina, linear, plane, incurvated, and perforated at the inside of the base. The leaves are divided first into five segments down to the base: the segments are again divided, each about halfway, into two or three lobes, which are sharply indented on the edges. The stalk is a foot high, and scarcely branched; the flower is yellow, globose, and spacious. It grows at the foot of mountains, and by the sides of rivulets. The country people in Sweden strew their floors and pavements on holidays with the flowers, which have a pleasant smell, and are ornamental in gardens. The asiaticus is little different, except that the corolla inclines to orange.

TRONAGE, the mayor and commonalty of the city of London, are ordained keepers of the beams and weights for weighing merchants' commodities, with power to assign clerks, porters, &c. of the great beam and balance, which weighing of goods and wares, is called tronage.

TROPÆOLUM, the *Indian cress*, or *nasturtium*, a genus of the octandria-monogynia class of plants, the flower of which consists of five roundish petals inserted into the divisions of the cup; the two upper petals are sessile; the three others have very long and barbated ungues: the fruit consists of three convex capsules, fulcated, and striated on one side, and angular on the other; the seeds are three, gibbous on one side, and angulated on the other, but upon the whole somewhat roundish, and striated deeply. There are five species.

TROPE. See RHETORIC.

TROPHIS, a genus of the dioecia tetrandria class and order of plants. There is no calyx and no female corolla; the male corolla is four-petalled; the style is two-parted; berry one-seeded. There is one species, the ramoom tree of Jamaica.

TROPHY, *tropæum*, among the antients, a pile or heap of arms of a vanquished enemy, raised by the conqueror in the most eminent part of the field of battle. The trophies were usually dedicated to some of the gods, especially Jupiter. The name of the deity to whom they were inscribed, was generally mentioned, as was that also of the conqueror. The spoils were at first hung upon the trunk of a tree; but instead of trees, succeeding ages erected pillars of stone, or brass, to continue the memory of their victories. To demolish a trophy was looked upon as a kind of sacrilege, because they were all consecrated to some deity. The representation of a trophy is often to be met with on medals of the Roman emperors, struck on occasion of victories; wherein, besides arms and spoils, are frequently seen one or two captives by the sides of the trophy.

TROPICS. See ASTRONOMY, and GEOGRAPHY.

TROVER is the remedy prescribed by the law, where any person is in possession of the property of another, which he unlawfully detains. Previous to commencing of this action, a demand of the property so detained, must be made in writing by some person properly authorized by the owner of the property; and upon refusal to restore it, the law presumes an unlawful conversion, and the party is entitled to this action, and will recover damages to the value of the property detained. As trover implies trespass, the smallest damages will carry costs. A similar action may be brought for the unlawful detention of any property, on which the specific article so detained may be recovered; but as articles detained must be precisely stated in the declaration, and is attended with some difficulty, this action is very seldom brought.

TROUT. See SALMO.

TROY-WEIGHT, one of the most antient of the different kinds used in Britain. The ounce of this weight was brought from Grand Cairo in Egypt, about the time of the crusades, into Europe, and first adopted in Troyes, a city of Champagne, whence the name. The pound English troy contains 12 ounces, or 5760 grains. It was formerly used for every purpose; and is still retained for weighing gold, silver, and jewels; in some degree for compounding medicines; for experiments in natural philosophy; and for comparing different weights with each other.

TROY-WEIGHT, *Scots*, was established by James VI. in the year 1618, who enacted, that only one weight should be used in Scotland, viz. the French troy stone of 16 pounds, and 16 ounces in the pound. The pound contains 7600 grains, and is equal to 17 oz. 6 dr. avoirdupois. The cwt. or 112 lb. avoirdupois, contains only 103 lb. $2\frac{1}{4}$ oz. of this weight, though generally reckoned equal to 104 lb. This weight is nearly, if not exactly, the same as that of Paris and Amsterdam; and is generally known by the name of Dutch weight. Though prohibited by the articles of union, it is still used in weighing iron, hemp, flax, most Dutch and Baltic goods, meal, butchers-meat, unwrought pewter and lead, and some other articles. See WEIGHTS.

TRUCE, in war, denotes a suspension of arms, or a cessation of hostilities between two armies, in order to settle articles of peace, bury the dead, or the like.

TRUFFLES, in natural history, a kind of subterraneous puff-ball, being a species of fungi, which grows under the surface of the earth. See LYCOPERDON.

TRUMPET, the loudest of all portable wind instruments, and consisting of a folded tube generally made of brass, and sometimes of silver.

The antients had various instruments of the trumpet kind, as the tuba, cornua, &c. Moses, as the scripture informs us, made two of silver to be used by the priests; and Solomon, Josephus tells us, made two hundred lik those of Moses, and for the same purpose.

The modern trumpet consists of a mouth-piece, near an inch across. The pieces which conduct the wind are called the branches; the parts in which it is bent the potences; and the canal between the second bend and the extremity the pavilion; the rings where the branches take asunder, or are soldered together, the knots, which are five in number, and serve to cover the joints.

One particular in this powerful and noble instrument is, that, like the horn, it only commands certain notes within its compass.

The trumpet produces, as natural and easy sounds, G above the bass-cliff note, or fiddle G, C on the first ledger line below in the treble, E on the first line of the stave, G on the second line, C on the third space, and all the succeeding notes up to C in alt, including the sharp of F, the fourth of the key.

Solo performers can also produce B flat (the third above the treble-cliff note) and by the aid of a newly invented slide many other notes which the common trumpet cannot sound are now produced.

A method has lately been discovered for varnishing the inside of trumpets, so as not to injure the fineness of the sound, and yet to prevent the deleterious effects occasioned by drawing in the oxide of copper into the lungs.

TRUMPET *marine*, a kind of monochord, consisting of three tables, which form its triangular body. It has a very narrow neck, with one thick string, mounted on a bridge, which is firm on one side, and tremulous on the other. It is struck with a bow by the right hand, while the thumb of the left is pressed on the string. The peculiarity of its sound, which resembles that of the trumpet, is produced by the tremulation of the bridges. This insrument, like that of the tones of which it imitates, is confined to certain notes, and some of these are imperfect.

TRUMPET, *harmonical*, an instrument that imitates the sound of a trumpet, which it resembles in every thing, excepting that it is longer, and consists of more branches; it is generally called sackbut.

TRUMPET, *speaking*, is a tube from six to fifteen feet long, made of tin, perfectly straight, and with a very large aperture; the mouth-piece being large enough to receive both lips.

The speaking-trumpet, or stentorophonic tube, as some call it, is used for magnifying sound, particularly that of speech, and thus causing it to be heard at a great distance. How it does this will be easy to understand from the structure of it, thus illustrated: Let ACB be the tube, BD the axis, and B the mouth-piece for conveying the voice to the tube. Plate Miscel. fig. 244.

It is then evident, when a person speaks at B in the trumpet, the whole force of his voice is spent upon the air contained in the tube, which will be agitated through the whole length of the tube; and by various reflections from the side of the tube; to the axis, the air along the middle part of the tube will be greatly condensed, and its momentum proportionably increased, so that when it comes to agitate the air at the orifice of the tube AC, its force will be as much greater than what it would have been without the tube, as the surface of a sphere, whose radius is equal to the length of the tube, is greater than the surface of the segment of such a sphere, whose base is the orifice of the tube. See SOUND.

For a person speaking at B, without the tube, will have the force of his voice spent in exciting concentric superficies of air all around the point B; and when those superficies or pulses of air are diffused as far as D every way, it is plain the force of the voice will be diffused through the whole superficies of a sphere whose radius is BD; but in the trumpet it will be so confined, that at its exit it will be only diffused through so much of that spherical surface of air, as corresponds to the orifice of the tube. But since the force is given, its intensity will be always inversely, as the number of particles it has to move; and therefore in the tube it will be to that without, as the superficies of such a sphere to the area of the large end of the tube nearly.

To make this matter yet plainer by calculation, let $BD=5$ feet, then will the diameter of the sphere $DE=10$ feet, the square of which is 100, which, multiplied by 0,7854, gives 78,54 square feet for the area of a great circle AHEFC. And, therefore, four times that area, viz. $4\times78{,}54=314{,}16$ square feet in the superficies of the aerial sphere. If now the diameter AC, of the end of a trumpet, is one foot, its area will be 0,7854; but 7854 : 314.16 : : 1 : 400, therefore the air at the distance of BD, will be agitated by means of the trumpet, with a force 400 times greater than by the bare voice alone. Again, it is farther evident how instruments of this form necessarily assist the hearing; for the weak and languid pulses of the air being received by the large end of the tube, and greatly multiplied and condensed by the tremulous motion of the parts of the tube, and air agitated by them, are conveyed to the ear by the small end, and strike it with an impetus as much greater than they would have done without it, as the area of the small end at B is less than the area of the larger end AC. From what has been said, it is evident the effect of the tube in magnifying sound, either for speaking or hearing, depends chiefly upon the length of the tube. But yet some advantage may be derived from the particular shape. Some very eminent philosophers have proposed the figure which is made by the revolution of a parabola about its axis, as the best of any, where the mouth-piece of the parabola, and, consequently, the sonorous rays will be reflected parallel to the axis of the tube. But this parallel reflection seems no way essential to the magnifying of sound; on the contrary, it appears rather to hinder such an effect, by preventing the infinite number of reflections and reciprocations of sound; in which, according to sir Isaac Newton, its augmentation principally consists. For all reciprocal motion, in every return, is augmented by its generating cause, which is here the tremulous motions of the parts of the tube. In every repercussion, therefore, from the sides of the tube, the agitations and pulses of confined air must necessarily be increased; and consequently this augmentation of the impetus of the pulses must be proportional to the number of such repercussions; and therefore, to the length of the tube, and to such a figure as is most productive of them. Whence it appears that the parabolic trumpet is of all the most unfit for this purpose, instead of being the best.

But there is one thing more which contributes to the augmenting of these agitations of air in the tube, and that is the proportion which the several portions of air bear to each other, when divided by transverse sections, at very small, but equal distances, from one end of the tube to the other. Thus, let those several divisions be made at the points *a, b, c, d, e*, &c. which let the right lines *ak, bl, cm, dn*, &c. be taken in geometrical proportion. Then will the portions of air contained between B and *a*, *a* and *b*, *b* and *cc*, *cc* and *d*, &c. be very nearly in the same proportion, as being in the same ratio with their bases, when the points of division are indefinitely near together.

But when any quantity of motion is communicated to a series of elastic bodies, it will receive the greatest augmentation when those bodies are in geometrical proportion. Therefore, since the force of the voice is impressed upon, and gradually propagated through, a series of elastic portions of air in a geometrical ratio to each other, it shall receive the greatest augmentation possible.

Now, since by construction it is $Ba = ab = bc = cd$, &c. and also $ak : bl :: bl : cm :: cm : dn$, and so on; therefore, the points *k, l, m, n, o, p, k, r, s*, as will, in this case, form that curve line which is called the logarithmic curve; consequently a trumpet, formed by the revolution of this curve about its axis, will augment the sound in a greater degree than any other figured tube whatever.

TRUMPET, *listening* or *hearing*, is an instrument invented by Joseph Landini, to assist the hearing of persons dull of that faculty, or to assist us to hear persons who speak at a great distance.

Instruments of this kind are formed of tubes, with a wide mouth, and terminating in a small canal, which is applied to the ear. The form of these instruments evidently shews how they conduce to assist the hearing, for the greater quantity of the weak and languid pulses of the air being received and collected by the large end of the tube, are reflected to the small end, where they are collected and condensed; thence entering the ear in this condensed state, they strike the tympanum with a greater force than they could naturally have done from the ear alone.

Hence it appears that a speaking-trumpet may be applied to the purpose of a hearing-trumpet, by turning the wide end towards the sound, and the narrow end to the ear.

TRUMPET-FLOWER. See BIGNONIA.

TRUMPET-SHELL, the English name of the buccinum of authors. See BUCCINUM.

TRUNCATED, in general, is an appellation given to such things as have, or seem to have, their points cut off: thus we say, a truncated cone, pyramid, leaf, &c.

In entomology it means when the elytra (or upper wings) are shorter than the abdomen, and terminated by a transverse line.

TRUNNIONS, or TRUNIONS *of a piece of ordnance*, are those knobs or bunches of the gun's metal, which bear her up on the cheeks of the carriage: and hence the trunnion-ring is the ring about a cannon, next before the trunnions.

TRUSS OF FLOWERS, is used by florists to signify many flowers growing together on the head of a stalk, as in the cowslip, auricula, &c.

TRUSS is also used for a sort of bandage or ligature made of steel, or the like matter, wherewith to keep up the parts, in those who have hernias or ruptures. See SURGERY.

TRUSSES, in a ship, are ropes made fast to the parrels of a yard, either to bind the yard to the mast when the ship rolls, or to hale down the yards in a storm, &c.

TRUST, is a right to receive profits of land, and to dispose of the land in equity. And one holding the possession and disposing of it at his will and pleasure, are signs of trust. Chan. Rep. 52.

A trust is but a new name given to an use, and invented to evade the statute of uses. 21 Vin. 493.

What is a declaration of trust, and when a trust shall be raised. By stat. 29 C. II. c. 3. all declaration or creation of trust shall be manifested by some writing signed by the party, or by his last will in writing, or else shall be void. And by sect. 9 of the same act, assignments of trust shall be in writing, signed by the party assigning the same, or by his last will, or else shall be of no effect.

What shall be deemed a trust by implication. By 29 Car. II. all declarations of trusts were to be made in writing; but in the said act there is a saving with regard to trusts resulting by implication of law, which are left on the footing whereon they stood before the act; now a bare declaration by parole before the act, would prevent any resulting trust. 2 Vern. 294.

If a man purchases lands in another's name, and pays the money, it will be a trust for him that paid the money, though no deed is made.

TRUSTEE, one who has an estate, or money, put or trusted in his hands, for the use of another. Where two or more persons are appointed trustees, if one of them only receives all or the greatest part of the profits of the lands, &c. and is in arrear, and unable to satisfy the person to whom he is seised in trust, the other, in that case, shall not be answerable for more than comes to his hands.

TUBE, in general, pipe, conduit, or canal; a cylinder, hollow withinside, either of lead, iron, wood, glass, or other matter, for the air, or some other fluid, to have a free passage or conveyance through.

Small silver or leaden tubes are frequently used by surgeons to draw off blood, matter, or water, from the different parts of the body. They are made of various sizes and shapes.

TUBE, in astronomy, is sometimes used for a telescope, or, more properly, for that part into which the lenses are fitted, and by which they are directed and used. See OPTICS.

TUBIPORA, a genus of zoophyta The generic character is, animal a nereis; coral consisting of erect, hollow, cylindrical, parallel aggregate tubes. There are ten species: the musica inhabits the American and Indian seas, is fixed to rocks and other corals; bright scarlet, consisting of an assortment of upright parallel tubes, rising over each other by stages, like cells of an honeycomb, divided by transverse partitions. The Indians use it in cases of strangury, and wounds inflicted by venomous animals.

TUBULARIA, a genus of zoophyta: stem tubular, simple or branched, fixed by the base: animal proceeding from the end of the tube, and having its head crested with tentacula. There are 26 species; the magnifica inhabits the West Indies, adhering to rocks, and is the most splendid genus of them all: it has the power of withdrawing its tentacula within the tube, and the tube within the rock on which it resides.

TUFAS, beds of lime deposited on vegetables, which by their destruction give great lightness and porousness to the mass.

TUG, in military affairs, *Fr.* A Turkish term for tail; a sort of standard, called so by the Turks. It consists of a horse's tail, which is fixed to a long pole or half-pike, by means of a gold button. The origin of this standard is curious. It is said, that the Christians having given battle to the Turks, the latter were broken, and in the midst of their confusion lost their grand standard. The Turkish general, being extremely agitated at the untoward circumstances which happened, most especially by the loss of the great standard, cut off a horse's tail with his sabre, fixed it to a half-pike, and holding it in his hand, rode furiously towards the fugitives, and exclaimed, 'Here is the great standard; let those who love me, follow into action.' This produced the desired effect. The Turks rallied with redoubled courage, rushed into the thickest of the enemy, and not only gained the victory, but recovered their standard. Other writers assert, that six thousand Turks having been taken prisoners during a general engagement, contrived to escape from their guard or escort, and afterwards fought so gallantly, that they regained another battle; that in order to recognize one another, they cut off a horse's tail, which they carried as a standard; that when they joined the Ottoman army, they still made use of the tug or tail; that the Turks, in consequence of the victory which was obtained under this new standard, looked upon it as a happy omen; and that since that period they have always fought under it as their banner, and the signal of success.

Whatever may have been the origin, it is certain, that when the grand signor takes the field in person, seven of these tails are always carried before him; and when he is in camp, they are placed in front of his tent.

The grand visier is entitled to three of these tails.

The three principal bashaws of the empire, viz. those of Bagdad, Grand Cairo, and Breda, have the grand signor's permission to use this mark of distinction, throughout the whole extent of their jurisdiction.

Those bashaws that are not visiers have the privilege of having two tails.

The beys, who are subordinate to the bashaws, have only one.

TULBAGIA, a genus of plants of the class and order hexandria monogynia. The corolla is funnel-form; nect. three-leaved; capsule superior. There are two species, bulbs of the Cape.

TULIP. See Tulipa.

TULIPA, *tulip*, a genus of plants of the class hexandria, and order monogynia, and in the natural system ranging under the 10th order, coronariæ. The corolla is hexapetalous and campanulated, and there is no style. The species of this genus are five; the sylvestris, or Italian yellow tulip, a native of the south of Europe; the gesneriana, or common tulip, a native of the Levant; the breyniana, or cape tulip, a native of the Cape of Good Hope, the biflora, and the suavolens.

1. The sylvestris, or wild European tulip, has an oblong bulbous root, sending up long narrow spear-shaped leaves; and a slender stalk, supporting at top a small yellow flower, nodding on one side, having acute petals.

2. The gesneriana, Gesner's Turky tulip of Cappadocia, or common garden tulip, has a large, oblong, tunicated, solid, bulbous root, covered with a brown skin, sending up long, oval, spear-shaped leaves; an upright round stalk, from half a foot to a yard high, and its top crowned with a large bell-shaped erect hexapetalous flower, of almost all colours and variegations in the different varieties.

This tulip, and its vast train of varieties, is generally cultivated for the ornament of our gardens, and much admired by all for its great variety and beautiful appearance; it grows freely in the open ground in any common soil of a garden, and proves a very great decoration to the beds and borders of the pleasure-ground for six weeks or two months in spring, by different plantings of early and late sorts; planting the principal part in autumn, and the rest towards Christmas, and in January or February. The autumn plantings will come earliest into bloom, and flower the strongest; and the others will succeed them in flowering. In summer, when the flowering is past, and the leaves and stalks assume a state of decay, the bulbs of the choicest varieties are generally taken up, the offsets separated, and the whole cleaned from filth; then put up to dry till October or November, and planted again for the future year's bloom.

Of this species, which is the florist's delight, the varieties may be divided into two principal classes, viz. 1. Early or dwarf spring tulips (præcoces). 2. Late flowering tall tulips (serotine). 1. Early tulips. The early tulips are, among florists, distinguished by the appellation of præcoces, (early) because they flower early in the spring, a month or more before the others; are much shorter stalked, and the flowers smaller, but in great reputation for their early bloom and their gay lively colours, both of self-colours, and broken into flaked variegations, such as reds, crimson, scarlet, carnations, violets, purples, yellow, &c. with flowers of each, edged and flaked with red, yellow, and white, in many diversities. 2. Late flowering common tulips. This class is denominated late flowering, and by the florists called serotines, because they blow later in the spring, a month or more, than the præcoces, *i. e.* not coming into flower before the end of April, May, and June. They are all of tall growth, supporting large flowers, and furnish an almost endless variety in the vast diversity of colours; after, they break from whole blowers into variegations and stripes, exceeding all others of the tulip kind in beauty and elegance of flower.

All the varieties are succeeded by plenty of ripe seed in July and August, contained in an oblong capsule of three cells, having the seeds placed on each other in double rows. By the seeds many new varieties may be raised, which however will not attain a flowering state till they are seven or eight years old; and after that will require two or three years, or more, to break into variegations, when the approved varieties may be marked, and increased by offsets of the root.

The colours in greatest estimation in variegated tulips are the blacks, golden yellows, purple-violets, rose, and vermilion, each of which being variegated various ways; and such as are striped with three different colours distinct and unmixed, with strong regular streaks, but with little or no tinge of the breeder, may be called the most perfect tulips. It is rare to meet with a tulip possessing all these properties.

As to the manner of obtaining this wonderful variety of colours in tulips, it is often accomplished by nature alone, but is sometimes assisted and forwarded by some simple operations of art; such as that, in the first place, when the seedling bulbs of the whole blower or breeder are arrived to full size, and have flowered once, to transplant them into beds of any poor dry barren soil, in order that, by a defect of nutriment in the earth, the natural luxuriance of the plant may be checked, and cause a weakness in their general growth, whereby they generally, in this weakened or infirm state, gradually change and break out into variegations, some the first year, others not till the second or third; and according as they are thus broken they should be planted in beds of good earth.

Another method to assist nature in effecting the breaking the breeding tulips into diversified colours, is to make as great a change as possible in the soil; if they were this year in a light poor soil, plant them the next in a rich garden mould, and another year in a compost of different earths and dungs; or transplant them from one part of the garden to another, or into different gardens, &c. or from one country to another; all of which contributes to assist nature in producing this desirable diversity of colours and variegations.

The double tulip is also a variety of the common tulip, and is very beautiful, though not in such estimation among the florists as the common single variegated sorts, not possessing such a profusion of variegations in the colours and regularity of stripes; they however exhibit an elegantly ornamental appearance.

Tulip roots are sold in full collection, consisting of numerous varieties, at most of the nurseries and seedsmen, who both propagate them themselves by offsets and seed, and import vast quantities annually from Holland, the Dutch being famous for raising the grandest collections of the finest tulips, and other bulbous flowers, in the greatest perfection.

TUMOUR, or Tumor, in medicine and surgery, a preternatural rising or hard swelling on any part of the body.

TUN, or Ton, originally signifies a large vessel or cask of an oblong form, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and used for stowing several kinds of merchandize, for convenience of carriage; as brandy, oil, sugar, skins, hats, &c. This word is also used for certain vessels of extraordinary bigness, serving to keep wine for several years.

Tun is also a certain measure for liquids; as wine, oil, &c. See Measure.

Tun is also a certain weight, whereby the burden of ships, &c. are estimated. See Ton and Weight.

TUNE, or Tone, in music, that property of sounds whereby they come under the relation of acute and grave to one another. See Tone, and Sound.

Sonorous bodies we find differ in tune: 1. According to the different kinds of matter; thus a wedge of silver sounds much more acute than a wedge of gold of the same shape and dimensions, in which case the tones are proportional to the specific gravity. 2. According to the different quantities of the same matter in bodies of the same figure, a solid sphere of brass, one foot diameter, sounds acuter than one of two feet diameter; in which case the tunes are proportional to the quantity of matter. Here then are different tunes connected with different specific gravities and quantities of matter, as their immediate cause. In effect, the measures of tune are only sought in the relations of the motions that are the cause of sound, which are no way so discernable as in vibrations of chords.

In the general we find that in two chords, all things being equal, except tension, or thickness, or length, the tunes are different; there must, therefore, be a difference in the vibrations owing to these different tensions, &c. which difference can only be in the velocity of the courses and recourses of the chords, through the spaces wherein they move to and again. Now, upon examining the proportion of the velocity, and the things just mentioned, wherein it depends, it is found, to a demonstration, that all the vibrations of the same chord are performed in equal times. Hence, as the tone of a sound depends on the nature of these vibrations, whose difference we can conceive no otherwise than as having different velocities; and as the small vibrations of the same chord are performed in equal times, and it is found true, in fact, that the sound of any body arising from any individual stroke, though it grows gradually weaker, yet continues the same tone from first to last; it follows, that the tone is necessarily connected with a certain quantity of time, in making every single vibration; or that a certain number of vibrations, accomplished in a given time, constitutes a certain determinate tune; for the more frequent those vibrations are, the more acute the tone; and, the slower and fewer they are, the more grave the sound, though performed in the same space of time; so that any given note of a tune is made by one certain measure of velocity of vibrations, that is, such certain courses and recourses of a chord or string, in such a certain space of time, constitute a determinate tune.

TUNGSTEN, a mineral found in Sweden, of an opaque white colour and great weight, whence its name tungsten, or ponderous stone. This ore was analysed by Scheele, who found that it was composed of lime and a peculiar earthy-like substance, which from its properties he called tungstic acid. The basis of the acid was found to contain a metal which was named tungsten, and which was obtained from the acid mixed with charcoal.

Tungsten, called by some of the German chemists scheelium, is of a greyish-white colour, or rather like that of iron, and has a good deal of brilliancy.

It is one of the hardest of the metals; for Vauquelin and Hecht could scarcely make any impression upon it with a file. It seems also to be brittle. Its specific gravity is 17.6. It is therefore the heaviest of the metals after gold and platinum.

It requires for fusion a temperature at least equal to 170° Wedgewood. It seems to have the property of crystallizing on cooling, like all the other metals.

It is not attracted by the magnet.

When heated in an open vessel, it gradually absorbs oxygen, and it is converted into an oxide. Tungsten seems capable of combining with two different proportions of oxygen, and of forming two different oxides; the black and the yellow.

The protoxide or black oxide may be obtained by heating the yellow oxide for some hours in a covered crucible. The peroxide or yellow oxide, known also by the name of tungstic acid, is found native in wolfram, and may be obtained from it by boiling three parts of muriatic acid on one of wolfram. The acid is to be decanted off in about half an hour, and allowed to settle. A yellow powder gradually precipitates. This powder is to be dissolved in ammonia, the solution is to be evaporated to dryness, and the dry mass kept for some time in a red heat. It is then yellow oxide in a state of purity. This oxide has no taste. It is insoluble in water, but remains long suspended in that liquid, forming a kind of yellow milk, which has no action on vegetable colours. When heated in a platinum spoon it becomes dark green; but before the blowpipe on charcoal it acquires a black colour. It is composed of 80 parts of tungsten and 20 of oxygen. Its specific gravity is 6.12.

1. The sulphuret of tungsten is of a bluish black colour, hard, and capable of crystallizing. Phosphorus is capable of combining with tungsten; but none of the properties of the phosphuret have been ascertained.

The simple incombustibles do not seem capable of uniting with tungsten.

The Elhuyarts alone attempted to combine tungsten with other metals. They mixed 100 grains of the metals to be alloyed with 50 grains of the yellow oxide of tungsten and a quantity of charcoal, and heated the mixture in a crucible. The result of their experiments is as follows:

With gold and platinum the tungsten did not combine. With silver it formed a button of a whitish-brown colour, something spongy, which with a few strokes of a hammer extended itself easily, but on continuing them it split in pieces. This button weighed 142 grains.

With copper it gave a button of a copperish red, which approached to a dark brown, was spongy, and pretty ductile, and weighed 133 grains. With crude or cast iron, of a white quality, it gave a perfect button, the fracture of which was compact and of a whitish brown colour: it was hard, harsh, and weighed 137 grains; and with lead it formed a button of a dull dark brown, with very little lustre, spongy, very ductile, and splitting into leaves when hammered: it weighed 127 grains.

The button formed with tin was of a lighter brown than the last, very spongy, somewhat ductile, and weighed 138 grains.

That with antimony was of a dark-brown colour, shining, something spongy, harsh, and broke in pieces easily: it weighed 108 grains.

That of bismuth presented a fracture, which, when seen in one light, was of a dark-brown colour, with the lustre of a metal, and in another appeared like earth, without any lustre; but in both cases an infinity of little holes could be distinguished over the whole mass. This button was pretty hard, harsh, and weighed 68 grains.

With manganese it gave a button of a dark-bluish-brown colour and earthy aspect; and on examining the internal part of it with a lens, it resembled impure dross of iron; it weighed 107 grains.

TUNGSTIC ACID. The substance called tungstic acid by Scheele and Bergman was discovered by Scheele in 1781. This philosopher obtained it from the tungstat of lime, by treating it with nitric acid and ammonia alternately. The acid dissolves the lime, and the ammonia combines with the tungstic acid. The ammoniacal solution, when saturated with nitric or muriatic acid, deposits a white powder, which is the tungstic acid of Scheele.

This powder has an acid taste, it reddens vegetable blues, and is soluble in 20 parts of boiling water. The De Luyarts have demonstrated, that this pretended acid is a compound of yellow oxide of tungsten, the alkali employed to dissolve it, and the acid used to precipitate it. Thus, when prepared according to the above-described process, it is a compound of yellow oxide, ammonia, and nitric acid. Their conclusions have been more lately confirmed by the experiments of Vauquelin and Hecht. This substance must therefore be erased from the class of acids, and placed among the salts.

The real acid of tungsten is a yellow powder; the method of procuring which, and its properties, have been already described under the denomination of yellow oxide of tungsten. It ought rather, as Vauquelin and Hecht have properly remarked, to be classed among the oxides than the acids; for it is insoluble in water, tasteless, and has no effect on vegetable blues. It agrees with the acids indeed in the property of combining with alkalies and earths, and perhaps also with some metallic oxides, and forming with them salts which have been denominated tungstats; but several other metallic oxides, those of lead, silver, and gold, for instance, possess the same property. These oxides, therefore, may be called acids with as much propriety as the yellow oxide of tungsten.

The affinities of this oxide, as far as they have been ascertained, are as follows:

Lime;	Soda,
Barytes,	Ammonia,
Strontian,	Glucina,
Magnesia,	Alumina,
Potass,	Zirconia.

The manner in which it was produced is evident: tungstic acid is composed of oxygen and tungsten; the oxygen combined with the carbon, and left the metal in a state of purity.

TUNICA, a kind of waistcoat or under-garment, in use amongst the Romans. They wore it within doors by itself, and abroad under the gown. The common people could not afford the toga, and so went in their tunics, whence Horace calls them populus tunicatus. The several sorts of the tunic were the palmata, the angusticlavia, and the laticlavia. The first was worn by generals in a triumph, and perhaps always under the toga picta; it had its name either from the great breadth of the clavi, or buttons, equal to the palm of the hand; or else from the figures of palms embroidered on it. It was by these three different sorts of tunics, that the three different orders of the Roman people were distinguished in habit.

TUNNAGE. See TONNAGE.

TUNNY. See SCOMBER.

TURBITH, or TURPETH-ROOT. See CONVOLVULUS.

TURBO, the WREATH, in zoology, a genus of insects belonging to the order of vermes testacea. The animal is of the snail kind; the shell consists of one spiral solid valve, and the aperture is orbicular. There are 166 species; of which the most remarkable are, 1. The littoreus, or periwinkle. This is abundant on most rocks far above low-water mark. The Swedish peasants believe that when these shells creep high up the rocks, they indicate a storm from the south. They are eaten by the poor people in most parts of this kingdom. Young lobsters are said to take up their lodging in the empty shells of these animals, which has given occasion to a notion that periwinkles are changed into lobsters. But we apprehend the mistake to have originated from the circumstance of the cancer diogenes, or soldier-crab, which is a kind of small lobster or shrimp, naturally naked, which takes shelter in the cast shells of harbinated shell-fish. 2. The clathrus, or barbed wreath, has a taper shell of eight spires, distinguished by elevated divisions, running from the aperture to the apex. There is a variety pellucid, with very thin edges. It is analogous to that curious and expensive shell, the wentle-trap. See Plate Nat. Hist. fig. 411.

TURBOT. See PLEURONECTES.

TURDUS, the thrush, a genus of birds belonging to the order of passeres. The bill is straight, bending towards the point, and slightly notched near the end of the upper mandible. The nostrils are oval, half covered with a membrane; the corners of the mouth are furnished with a few slender hairs, and the tongue is slightly jagged at the end. There are 136 species, of which seven are British, the viscivorus, pilaris, iliacus, musicus, roseus, merula, and torquatus.

1. The viscivorus, or missel, is the largest of the genus. Its length is eleven inches; its breadth sixteen and a half. The bill is shorter and thicker than that of other thrushes; dusky, except the base of the lower mandible, which is yellow. The irides are hazel. Head, back, and lesser coverts of the wings, are of a deep olive-brown. The lower part of the back is tinged with yellow. The lowest order of lesser coverts, and the great coverts, are brown, the first tipped with white, the last both tipped and edged with the same colour. The inner coverts of the wings white. The tail is brown; the three outermost feathers tipped with white. The cheeks and throat are mottled with brown and white; the breast and belly are whitish yellow, marked with large spots of black; the legs are yellow. These birds build their nests in bushes, or on the side of some tree, and lay four or five eggs: their note of anger or fear is very harsh, between a chatter and shriek. Its song, however, is very fine; which it begins sitting on the summit of a high tree, very early in the spring, often with the new year, in blowing showery weather, which makes the inhabitants of Hampshire call it the storm-cock. It feeds on insects, holly and misseltoe berries, which are the food of all the thrush kind: in severe snowy weather, when there is a failure of their usual diet, they are observed to scratch out of the banks of hedges the root of arum, or the cuckoo-pint; this is remarkably warm and pungent, and a provision suitable to the season.

2. The pilaris, or fieldfare, is in length ten inches, in breath seventeen. The head is ash-coloured inclining to olive, and spotted with black; the back and greater coverts of the wings of a fine deep chesnut; the tail is black; the lower parts of the two middlemost feathers, and the interior upper sides of the outmost feathers, excepted; the first being ash-coloured, the latter white. The legs are black; the talons very strong. This bird passes the summer in the northern parts of Europe; also in Lower Austria. It breeds in the largest trees: feeds on berries of all kinds, and is very fond of those of the juniper. Fieldfares visit our islands in great flocks about Michaelmas, and leave us the latter end of February or the beginning of March.

These birds and the redwings were the turdi of the Romans, which they fattened with crumbs of figs and bread mixed together. Varro informs us that they were birds of passage, coming in autumn, and departing in the spring. They must have been taken in great numbers; for, according to Varro (lib. 3. c. 5.), they were kept by thousands together in their fattening aviaries. They do not arrive in France till the beginning of December.

3. The musicus, or throstle, is in length nine inches, in breadth thirteen and a half. In colour, it so nearly resembles the missel-thrush, that no other remark need to be added, but that it is less, and that the inner coverts of the wings are yellow. The throstle is the finest of our singing birds, not only for the sweetness and variety of its notes, but for the long continuance of its harmony; for it obliges us with its song for near three parts of the year. Like the missel-bird, it delivers its music from the top of some high tree; but to form its nest descends to some low bush or thicket: the nest is made of earth, moss, and straw, and the inside is curiously plaistered with clay, or rather clay and cow-dung mixed. It lays five or six eggs, of a pale bluish green, marked with dusky spots.

4. The iliacus, or redwing, has a very near resemblance to the throstle; but is less: their colours are much the same; only the sides under the wings and the inner coverts in this are of a reddish orange, in the throstle yellow; above each eye is a line of yellowish white, beginning at the bill and passing towards the hind part of the head. These birds appear in Great Britain a few days before the fieldfare; they come in flocks, and from the same countries as the latter. With us they have only a disagreeable piping note; but in Sweden, during the spring, they sing very finely, perching on the top of some tree among the forests of maples. They build their nests in hedges, and lay six blueish-green eggs spotted with black.

5. The merula, or blackbird; when the male has attained its full age, it is of a fine deep black, and the bill of a bright yellow; the edges of the eyelids yellow. When young, the bill is dusky, and the plumage of a rusty black, so that they are not to be distinguished from the females; but at the age of one year they attain their proper colour. This bird is of a very retired and solitary nature, and frequents hedges and thickets, in which it builds earlier than any other bird; the nest is formed of moss, dead grass, fibres, &c. lined and plaistered with clay, and that again covered with hay or small straw. It lays four or five eggs of a dusky green colour, marked with irregular spots. The note of the male is extremely fine, but too loud for any place except the woods; it begins to sing early in the spring, continues its music part of the summer, desists in the moulting season, but resumes it for some time in September and the winter months.

6. The torquatus, or ring-ouzel, is superior in size to the blackbird; the length is eleven inches, breadth seventeen. The bill in some is wholly black, in others the upper half is yellow; on each side the mouth are a few bristles; the head and whole upper part of the body are dusky, edged with pale brown; the quill-feathers and the tail are black. The coverts of the wings, the upper part of the breast, and the belly, are dusky, slightly edged with ash-colour. The middle of the breast is adorned with a white crescent, the horns of which point to the hind part of the neck. In some birds this is of a pure white, in others of a dirty hue. In the females and in young birds this mark is wanting, which gave occasion to some naturalists to form two species of them. The ring-ouzel inhabits the Highland hills, the north of England, and the mountains of Wales. They are also found to breed in Dartmoor, in Devonshire, and in banks on the sides of streams. The places of their retreat are not known. In Scotland and Wales they breed in the hills, but descend to the lower parts to feed on the berries of the mountain-ash. They migrate in France at the latter season; and appear in small flocks about Monthard in Burgundy, in the beginning of October, but seldom stay above two or three weeks.

To these we shall add the description of the orpheus, or mocking thrush, which is a native of America. It is about the size of a thrush, of a white and grey colour, and a reddish bill. It is possessed not only of its own natural notes, which are musical and solemn, but it can assume the tone of every other animal in the wood, from the wolf to the raven. It seems even to sport itself in leading them astray. It will at one time allure the lesser birds with the call of their males, and then terrify them when they come near with the screams of the eagle. There is no bird in the forest but it can mimick; and there is none that it has not at times deceived by its call. But, unlike such as we usually see famed for mimicking with us, and who have no particular merit of their own, the mock-bird is ever sure to please when it is most itself. At those times it usually frequents the houses of the American planters; and sitting all night on the chimney-top, pours forth the sweetest and the most various notes of any bird whatever. It would seem, if accounts are true, that the deficiency of most other song-birds in that country is made up by this bird alone. They often build their nests in the fruit-trees about houses, feed upon berries and other fruits, and are easily rendered domestic. See Plate Nat. Hist. fig. 412.

TURIONES, among herbalists, denotes the first young tender shoots, which plants annually put forth.

TURKEY. See MELEAGRIS.

TURMERIC. See CURCUMA.

TURNAMENT, or TOURNAMENT, a martial sport, or exercise, which the antient cavaliers used to perform to shew their bravery and address.

TURNERA, a genus of the pentandria trigynia class of plants, the flower of which consists of five petals obversely cordated, and sharp-pointed; the fruit is an oval, unilocular capsule, containing a great many oblong and obtuse seeds. There are nine species.

TURNING, the art of forming hard bodies, as wood, ivory, or iron, into a round or oval shape, by means of a machine called a lathe. This art was well known to the antients, and seems to have been carried by them to a very great degree of perfection; at least, if we believe the testimony of Pliny and several other authors, who tell us, that those precious vases enriched with figures in half-relief, which still adorn our cabinets, were turned on the lathe. See LATHE.

The art of turning is of considerable importance, as it contributes essentially to the perfection of many other arts. The architect uses it for many ornaments, both within and without highly finished houses. The mathematician, the astronomer, and the natural philosopher, have recourse to it, not only to embellish their instruments, but also to give them the necessary dimension and precision. In short, it is an art absolutely necessary to the goldsmith, the watchmaker, the joiner, and the smith.

Turning is performed by the lathe, of which there are various kinds, and several instruments, as gouges, chisels, drills, formers, and screw-tales, used for cutting what is to be turned into its proper form as the lathe turns round. See Plate Miscel. fig. 131; and Plate Lamp, &c. fig. 6, &c.

The lathe should be fixed in a place very well lighted; it should be immoveable, and neither too high nor too low. The puppets should neither be so low as to oblige the workman to stoop in order to see his work properly, nor so high that the little chips, which he is continually driving off, should come into his eyes.

The piece to be turned should be rounded, (if it is wood) before it is put on the lathe, either with a small hatchet made for the purpose, or with a plane, or with a file, fixing it in a vice, and shaving it down till it is every where almost of an equal thickness, and leaving it a little larger than it is intended to be when finished off. Before putting it on the lathe, it is also necessary to find the centre of its two end surfaces, and that they should be exactly opposite to each other, that when the points of the puppets are applied to them, and the piece is turned round, no side may belly out more than another. To find these two centres, lay the piece of wood to be turned upon a plank; open a pair of compasses to almost half the thickness of the piece, fix one of the legs in the plank, and let the point of the other touch one of the ends of the piece, brought into the same plane with the plank on which the compasses are fixed, and very near the fixed leg. Describe four arches on that end at equal distances from each other, at the circumference of the end, but intersecting one another within; the point of intersection is the centre of the end. In the same manner must the centre of the other end be found. After finding the two centres, make a small hole at each of them, into which insert the points of the puppets, and fix the piece so firmly as not to be shaken out, and yet loose enough to turn round without difficulty.

The piece being thus fixed, it is necessary in the next place to adjust the cord, by making it pass twice round the piece, and in such a manner, that the two ends of the cord, both that which is fixed to the spang and to the footboard, come off on the side on which the turner stands, that the piece may move against the edge of the cutting-tool and be turned. If the lathe is moved by a wheel, the manner of adjusting the cord needs no direction.

If the workman does not chuse to be at the trouble to find the two centres of the piece in the manner described above, let him lay, as nearly as he can, the centre of one end upon the point of the left hand puppet, and then let him push forward the right hand puppet, striking it with a mallet till its point is as near as can be in the centre of the other end of the piece; and then fixing the right hand puppet by a gentle blow of the mallet on the key, let him turn round the piece to see by the eye if the centres have been properly found. If any part of it bellies out, let him strike that part gently with the mallet till it goes properly; then let him strike one of the puppets pretty smartly to drive the points into the piece, and afterwards fix the puppet by striking the key. If the workman cannot judge by the eye whether the piece is turning properly round its centres or not, he should apply gently the point of an instrument called a triangular graver, leaning it on the rest, and it will mark by a line the place where the piece is out of its centre; and by striking upon this line with a mallet, the piece can easily be placed properly. The rest, of which we have just spoken, ought to be placed upon the two arms of the lathe, and fixed with screws as near the piece as the workman pleases.

The piece being fixed between the two points of the puppets, the cord adjusted, and the rest fixed as near the work as possible without touching it; the workman is now to take a gouge of a proper size in his left hand, and hold it by the handle a little inclined, keeping the back of the hand lowermost. With his right hand, the back of which is to be turned upwards, he is to grasp it near the end on this side of the rest; then leaning the gouge on the rest, he is to present the edge of it a little higher than the horizontal diameter of the piece, so as to form a kind of tangent to its circumference; then putting the right foot on the footboard, and turning round the wheel, and holding the gouge firmly on the rest, the piece will be cut neatly. In the same manner are the chisels, formers, and other instruments to be used, taking care that the wood shall be cut equally, and that the instrument shall not be pushed improperly, sometimes stronger than at others; and taking care also, that the instrument used does not follow the work, but that it is kept firmly in the hand without yielding.

The young turner ought to endeavour to acquire the management of the gouge and the chisel, which are the instruments by far the most frequently used, and the most necessary in this art; by them, almost entirely, are the soft woods turned; as for hard woods and other things, as box, ebony, horn, ivory, and the metals, they are hardly ever turned except by shaving off. In that case gravers are to be used with square, round, or triangular mouths. They should be held horizontally while applied to the wood, and not obliquely as directed for the gouge and the chisel.

After the work is completely turned, it is next to be polished, and this cannot be done with the instruments hitherto mentioned. Soft woods, as pear-tree, hazel, and maple, ought to be polished with shark-skin or Dutch rushes. There are different species of sharks: some of which have a greyish, others a reddish skin. Shark-skin is always the better to be a good deal used; at first it is too rough for polishing. The Dutch rush is the equisetum hyemale of Linnæus, which grows in moist places among mountains. It is remarkable for having flinty particles in the substance of its leaves, which render it so useful in polishing. It has a naked, simple, and round stem, about the thickness of a writing-pen. The oldest plants are the best. Before using them they should be moistened a little, otherwise they break in pieces almost immediately, and render it exceedingly difficult to polish with them. They are particularly proper for smoothing hard woods, as box, lignum-vitæ, ebony, &c. After having cleaned up the piece well, it should be rubbed gently either with wax or olive-oil, then wiped clean and rubbed with its own raspings or with a cloth a little worn. Ivory, horn, silver, and brass, are polished with pumice-stone finely pounded and put upon leather or a linen cloth a little moistened: with this the piece is rubbed as it turns round in the lathe; and to prevent any dirt from adhering to any part of it, every now and then it is rubbed gently with a small brush dipt in water. To polish very finely, the workmen make use of tripoli, and afterwards of putty or calx of tin. Iron and steel are polished with very fine powder of emery; this is mixed with oil, and put between two pieces of very tender wood, and then the iron is rubbed with it. Tin and silver are polished with a burnisher, and that kind of red stone called in France sanguine dure. They may be polished also with putty, putting it dry on shammy-skin or with the palm of the hand.

To succeed in turning iron, it is necessary to have a lathe exceedingly strong in all its parts, and exceedingly well fixed. The puppets should be short, and the rest well fixed very near the work; the back of the rest should be two or three lines lower than the iron to be turned.

The lathe and other instruments being prepared, it is necessary to determine the length and thickness of the iron to be turned according to the design which is to be executed, and to make a model of it in wood a little thicker than it ought to be; then one exactly like this is to be forged of the best iron that can be procured; that is, it must not be new, but well prepared and well beaten with hammers; it must have no flaws, nor cracks, nor pimples. New iron, which has not been well beaten, often contains round drops of cast iron, called by the workmen grains, which blunt the edges of the gouges, chisels, and other instruments used for cutting; break them, or make them slide. The iron being forged according to the model, it should be annealed, that is, heated red hot, and allowed to cool slowly on the coals till the fire goes out of itself. Some people, to soften the iron, cover it over with clay and allow it to cool. The iron cylinder being thus made, it is next to be put upon the lathe, finding the centres as formerly directed, and boring a small hole in them that the iron may not escape from the points.

The points should be oiled from time to time to prevent their being excessively heated and spoiled while the iron is turning. A crotchet is then to be applied to the iron to be turned a little above its centre, pretty gently, and by this means the inequalities of the cylinder will be taken off. Other instruments are then to be applied to mould the iron according to the model; and whenever any of them grow hot, they are to be plunged into a bason of water lying beside the workman. If the iron, after being properly turned, is to be bored like a gun-barrel, one of the puppets is to be removed, and another substituted in its place, having a square hole through it, into which the collar of the iron is to be fixed firmly, so as not to shake; then borers are to be applied, like those which locksmiths use to bore keys; and beginning with a small one, and afterwards taking larger ones, the hole is to be made as wide and deep as necessary; great care must be taken to hold the borers firm to the rest, otherwise there is danger of not boring the hole straight. The borer must be withdrawn from time to time to oil it and to clean the hole. Since it is difficult to make a hole quite round with borers alone, it is necessary to have also an instrument a good deal smaller than the hole, one of the sides of which is sharp, very well tempered, and a little hollow in the middle. This instrument being fixed in a pretty long handle, is to be applied with steadiness to the inner surface of the hole, and it will entirely remove every inequality that may have been there before its application.

For turning ovals, a lathe of somewhat a different construction is used. The axis or spindle, having on it the pulley over which the band-cord passes for turning the lathe, is fixed between the two puppets so as to turn round easily; one end of it passes through one of the puppets, and to it is firmly fixed a circular plate of brass, so that it turns round along with the spindle. Upon this plate two brazen segments of circles are fastened, the circumferences of which correspond to the circumference of the plate; their chords are parallel, and equally distant from the centre of the plate, so that they leave a distance between them. They have a groove in each of them; in these grooves another plate is placed, which exactly fills up the space between the two grooves, but is shorter than the diameter of the larger circular plate on which it is laid. This plate is made to slide in the grooves. To its centre is annexed a short spindle, on which the piece of wood to be turned is fixed. When the lathe is set a going, the circular plate moves round, and carries the piece along with it; the plate of brass on which the piece is fixed, being fixed loosely in the grooves already described, slides down a little every time that the grooves become perpendicular to the floor (and there are particular contrivances to prevent it from sliding down too far); and by these two motions combined (the circular one of the large plate, and the straight one of the small), the circumference of the piece of wood to be turned necessarily describes an oval; and gouges or other tools being applied in the usual manner, supported on the rest, it is cut into an oval accordingly. The small plate may be made to slide either more or less in the grooves; and by this contrivance the transverse diameter of the oval, or rather ellipse, may be made longer or shorter at pleasure. Another, and still simpler method if possible, of turning ovals, is this: Take two ovals of metal, exactly of the size of the oval which you intend to make; fix them firmly on the spindle of the lathe, so as to turn round with it; fix between them the wood to be turned, and then it is easy, by the help of chisels and other tools, to cut it, as the lathe goes, into exactly the figure of the external ovals. Or an oval may be formed by placing the wood, or whatever is to receive that shape, obliquely on the lathe. There are several other ingenious methods of turning, but our bounds do not permit us to enter upon them. We shall therefore conclude this article with a number of receipts, which every turner ought to know.

1. The method of moulding boxes both of shell and horn. In the first place, form a proper mould, which must consist of two pieces, viz. of a circle about half an inch thick, which should slope a little in order to draw out the moulded shell the more easily; and a ring fitted to the outside of the circle, so that both together make the shape of a box. These two pieces being adjusted, it is necessary to round the shell to be moulded of such a size, that when moulded, it will be a little higher than the ring of the mould, that there may be no deficiency. The mould is then to be put into a press on a plate of iron, exactly under the screw of the press; put then the shell upon the circle of the mould, so that its centre also is exactly opposite to the screw of the press: then take a piece of wood formed into a truncated cone, and not so thick as the diameter of the circle of the mould, nor so deep as the ring; then put a plate of iron above the cone, and screw down the press gently and cautiously till the whole is well fixed; then plunge the whole into a cauldron of boiling water placed above a fire. In eight or ten minutes the shell or horn will begin to soften; screw the press a little firmer that the wooden cone may sink into the softened shell: repeat this from time to time till the cone is quite sunk in the mould; then take out the press and plunge it into cold water. When it is cold, take the box now formed out of the mould, and put into the inside of it a new mould of tin exactly of the form you wish the inside of the box to be; do the same with the outside, put it again into the press, and plunge it into boiling water; screw the press gradually till the box is fashioned as you desire.

2. Method of preparing green wood so that it will not split in the turning. Having cut your wood into pieces of a proper size, put it into a vessel full of a ley made with wood ashes. Boil it there about an hour; then, taking the cauldron off the fire, allow the ley to cool; then take out the wood and dry it in the shade.

3. Method of giving an ebony-black to hard and fine woods. After forming the wood into the destined figure, rub it with aqua fortis a little diluted. Small threads of wood will rise in the drying, which you will rub off with pumice-stone. Repeat this process again, and then rub the wood with the following composition: Put into a glazed earthen vessel a pint of strong vinegar, two ounces of fine iron-filings, and half a pound of pounded galls, and allow them to infuse for three or four hours on hot cinders. At the end of this time augment the fire, and pour into the vessel four ounces of copperas (sulphat of iron), and a chopin of water having half an ounce of borax and as much indigo dissolved in it; and make the whole boil till a froth rises. Rub several layers of this upon your wood; and, when it is dry, polish it with leather on which you have put a little tripoli.

4. Method of giving to plum-tree the colour of Brazil wood. Slack lime with urine, and bedaub the wood over with it while it is hot; allow it to dry; then take off the coat of lime, and rub it with chamois-skin well oiled. Or, steep your wood in water having a quantity of alum dissolved in it, five or six hours, kept lukewarm during a night: and when it is dry, rub it, as before directed, with chamois-skin well oiled.

5. Method of giving a fine black colour to wood. Steep your wood for two or three days in lukewarm water in which a little alum has been dissolved; then put a handful of logwood, cut small, into a pint of water, and boil it down to less than half a pint. If you then add a little indigo, the colour will be more beautiful. Spread a layer of this liquor quite hot on your wood with a pencil, which will give it a violet-colour. When it is dry, spread on another layer; dry it again, and give it a third; then boil verdegris at discretion in its own vinegar, and spread a layer of it on your wood; when it is dry, rub it with a brush, and then with oiled chamois-skin. This gives a fine black, and imitates perfectly the colour of ebony.

6. Method of cleaning and whitening bones before using them. Having taken off with a saw the useless ends of the bones, make a strong ley of ashes and quick-lime, and into a pailful of this ley put four ounces of alum, and boil the bones in it for an hour; then take the vessel containing the ley off the fire, and let it cool; then take out the bones and dry them in the shade.

7. Method of soldering shells. Clean the two sides of the shells which you wish to join together; then, having joined them, wrap them up in linen folded double and well moistened; then heat two plates of iron pretty hot, that they may keep their heat for some time; and putting your shells rolled up between them under a press, which you must screw very tight, leave them there till the whole is cold, and they will be soldered. If you do not succeed the first time, repeat the process.

8. Method of moulding shells. Put six pints of water into a kettle; add to it an ounce of olive or other oil; make the water boil; then put in your shell, and it will grow soft. Take it out, and put it into a mould under a press, and it will take the figure you want. This must be done quickly; for if the shell cools ever so little, the process will fail. It will not require much pressure.

9. Method of tinging bones and ivory red. Boil shavings of scarlet cloth in water. When it begins to boil, throw in a quarter of a pound of ashes made from the dregs of wine, which will extract the colour: then throw in a little rock alum to clear it, and pass the water through a linen cloth. Steep your ivory or bone in aqua fortis, and put it into the water. If you wish to leave white spots, cover the places destined for them with wax.

10. To tinge ivory black. Steep the ivory during five or six days in water of galls, with ashes made with dried dregs of wine and arsenic; then give it two or three layers of the same black with which plum-tree is blackened in order to imitate ebony. Or dissolve silver in aqua fortis, and put into it a little rose water. Rub the ivory with this, and allow it to dry in the sun.

11. Method of hardening wood to make pulleys. After finishing the pulley, boil it seven or eight minutes in olive-oil, and it will become as hard as copper.

12. To make Chinese varnish. Take of

gum-lac in grains four ounces; put it into a strong bottle with a pound of good spirit of wine, and add about the bulk of a hazel-nut of camphor. Allow them to mix in summer in the sun, or in winter on hot embers for twenty-four hours, shaking the bottle from time to time. Pass the whole through a fine cloth, and throw away what remains upon it. Then let it settle for twenty-four hours, and you will find a clear part in the upper part of the bottle, which you must separate gently and put into another vial, and the remains will serve for the first layers.

TURNPIKE, a gate set up across a road, watched by an officer for the purpose, in order to stop travellers, waggons, coaches, &c. to take toll of them towards repairing or keeping the roads in repair.

Justices of the peace, and other commissioners, are authorised to appoint surveyors of the roads, and collectors of toll. In case any persons shall drive horses or other cattle through grounds adjoining to the highways, thereby to avoid the toll, they are liable to forfeit 10*s*. Likewise if any one assaults a collector of the tolls, or by force passes through a turnpike-gate without paying, he forfeits 5*l*. leviable by justices of peace; and maliciously pulling down a turnpike is deemed felony, &c. It is also enacted, that 20*s*. shall be paid for every hundred that a carriage with its loading weighs above 6000 pounds weight, and that engines may be set up at turnpikes for weighing such carriages.

TURPENTINE. See Pinus, and Resins.

TURRÆ, a genus of plants of the class and order decandria monogynia. The calyx is one-leafed, bell-shaped, five-toothed, very small, permanent. There are five species, shrubs of the East Indies.

TURRITIS, *tower-mustard*, a genus of the tetradynamia siliquosa class of plants, with a tetrapetalous cruciform flower: its fruit is an extremely long pod, containing numerous seeds. There are eight species.

TUSCAN ORDER. See Architecture.

TUSSILAGO, *colt's-foot*, a genus of plants of the class syngenesia, and order polygamia superflua; and in the natural system ranging under the 49th order, compositæ. The receptacle is naked; the pappus simple; the scales of the calyx equal, of the same height as the disk, and somewhat membranaceous. There are fourteen species, three of which are indigenous to Britain, the farfara, hybrida, and petasites. The farfara, or common colt's-foot, grows plentifully on the banks of rivulets, or in moist and clayey soils. The leaves were formerly smoked in the manner of tobacco, and a syrup or decoction of them and the flowers stands recommended in coughs and other disorders of the breast and lungs. It seems now to be almost entirely rejected. The downy substance under the leaves, boiled in a lixivium with a little saltpetre, makes excellent tinder. The petasites, or common butter-bur, is frequent in wet meadows, and by the sides of rivers. Its leaves are the largest of any plant in Great Britain, and in heavy rains afford a seasonable shelter to poultry and other small animals. The root dug up in the spring is resinous and aromatic.

TUTOR, in the civil law, is one chosen to look to the person and estate of children left by their fathers and mothers in their minority. A person nominated tutor either by testament, or by the relations of the minor, is to decline that office if he has five children alive, if he has any other considerable tutorage, if he is under twenty-five years of age, if he is a priest, or a regent in an university, or if he has any law-suit with the minors, &c. The marriage of a pupil, without the consent of his tutor, is invalid. Tutors may do any thing for their pupils, but nothing against them; and the same laws which put them under a necessity of preserving the interest of the minors, put them under an incapacity of hurting them.

Tutor, is also used in our universities for a member of some college or hall, who takes on him the instruction of some young students in the arts or faculties.

TUTORAGE, *tutela*, in the civil law, a term equivalent to guardianship in the common law, signifying an office imposed on any one to take care of the effects of one or more minors. See Guardian, and Tutor.

By the Roman law, there are three kinds of tutorage; testamentary, which is appointed by the father's testament; legal, which is given by the law to the nearest relation; and dative which is appointed by the magistrate. But in all customary provinces, all tutorages are dative and elective; and though the father has by testament nominated the next relation to his pupil, yet is not that nomination of any force, unless the choice is confirmed by that of the magistrate, &c. By the Roman law, tutorage expires at fourteen years of age.

TUTTY. See Zinc.

TWA-NIGHTS GESTE, among our ancestors, was a guest that staid at an inn a second night, for whom the host was not answerable for any injury done by him, as he was in case of a third night-awn hynde.

TWELF-HINDI, among the English Saxons, was where every person was valued at a certain price; and if any injury was done either to a person or his goods, a pecuniary mulct was imposed, and paid in satisfaction of that injury, according to the worth and quality of that person to whom it was done, in which case such as were worth 1200 shillings were called twelf-hindi; and if an injury was done to such persons, satisfaction was to be made accordingly.

TWI-HINDI, among our Saxon ancestors, were persons valued at 200*s*. These men were of the lowest degree, and if such were killed, the mulct was 30*s*. See Twelfhindi.

TWILIGHT. See Astronomy.

TYCHONIC SYSTEM or Hypothesis, an order or arrangement of the heavenly bodies, of an intermediate nature betwen the Copernican and Ptolemaic, or participating alike of them both.

This system had its name and original from Tycho Brahe, a nobleman of Denmark who lived in the latter part of the 17th century. This philosopher, though he approved of the Copernican system, yet could not reconcile himself to the motion of the earth; and being on the other hand convinced the Ptolemaic scheme could not be true, he contrived one different from either. In this the earth has no motion allowed it, but the annual and diurnal phenomena are solved by the motion of the sun about the earth, as in the Ptolemaic scheme; and those of Mercury and Venus are solved by this contrivance, though not in the same manner, nor so simply and naturally, as in the Copernican system. The Tychonic system then supposed the earth in the centre of the world, that is, of the firmament of stars, and also of the orbits of the sun and moon; but at the same time it made the sun the centre of the planetary motions, viz. of the orbits of Mercury, Venus, Mars, Jupiter and Saturn. Thus the sun with all its planets, was made to revolve about the earth once a year, to solve the phenomena arising from the annual motion, and every twenty-four hours, to account for those of the diurnal motion. But this hypothesis is so monstrously absurd, and contrary to the great simplicity of nature, and, in some respects, even contradictory to appearances, that it obtained but little credit, and soon gave way to the Copernican system.

After this scheme had been proposed for some time, it received a correction by allowing the earth a motion about its axis to account for the diurnal phenomena of the heavens; and so this came to be called the semi-tychonic system. But this was still void of the truth, and encumbered with such hypotheses as the true mathematician and the genuine philosopher could never relish.

TYLE. See Tile.

TYMPANUM, or Tympan, in mechanics, a kind of wheel placed round an axis or cylindrical beam, on the top of which are two levers or fixed staves, for the more easy turning the axis, in order to raise a weight required. The tympanum is much the same with the peritrochium, but that the cylinder of the axis of the peritrochium is much shorter, and less than the cylinder of the tympanum.

Tympanum *of a machine*, is also used for a hollow wheel, wherein one or more people, or other animals, walk to turn it; such as that of some cranes, calenders, &c.

TYPE, a copy, image, or resemblance of some model. This word is much used among divines, to signify a symbol, sign, or figure of something to come.

Type, among letter-founders and printers, the same with letter.

Types *for printing*. In the business of cutting, casting, &c. letters for printing, the letter-cutter must be provided with a vice, hand-vice, hammers, and files of all sorts for watchmakers' use; as also gravers and sculpters of all sorts, and an oil-stone, &c. suitable and sizeable to the several letters, to be cut: a flat gage made of box to hold a rod of steel, or the body of a mould, &c. exactly perpendicular to the flat of the using file: a sliding-gage, whose use is to measure and set off distances between the shoulder and the tooth, and to mark it off from the end, or from the edge of the work; a face-gage, which is a square notch cut with a file into the edge of a thin plate of steel, iron, or brass, of the thickness of a piece of common tin, whose use is to proportion the face of each sort of letter, viz. long letters, ascending letters, and short letters. So there must be three gages, and the gage for the long letters is the length of the whole body supposed to be divided into 42 equal parts. The gage for the ascending letters, Roman and

Italic is $\frac{5}{7}$, or 30 parts of 42, and 33 parts for the English face. The gage for the short letters is $\frac{3}{7}$, or 18 parts of 42 of the whole body for the Roman and Italic, and 22 parts for the English face.

The Italic and other standing gages are to measure the scope of the Italic stems, by applying the top and bottom of the gage to the top and bottom lines of the letters, and the other side of the gage to the stem; for when the letter complies with these three sides of that gage, it has its true shape.

The next care of the letter-cutter is to prepare good steel punches, well tempered, and quite free from all veins of iron; on the face of which he draws or marks the exact shape of the letter with pen and ink if the letter is large, or with a smooth blunted point of a needle if it is small; and then with sizeable and proper-shaped and pointed gravers and sculpters, digs or sculps out the steel between the strokes or marks so made on the face of the punch, and leaves the marks standing on the face. Having well shaped the inside strokes of his letter, he deepens the hollows with the same tools; for, if a letter is not deep in proportion to its width, it will, when used at press, print black, and be good for nothing. This work is generally regulated by the depth of the counter punch. Then he works the outside with proper files till it is fit for the matrice.

But before we proceed to the sinking and justifying of the matrices, we must provide a mould to justify them by, of which there are draughts in Plate Miscel. figs. 1*, 2*. Every mould is composed of an upper and an under part. The under part is delineated in fig. 1*. The upper part is marked fig. 2*. and is in all respects made like the under part excepting the stool behind, and the bow or spring also behind; and excepting a small roundish wire between the body and carriage, near the break, where the under part has a small rounding groove made in the body. This wire, or rather half-wire, in the upper part, makes the nick in the shank of the letter, when part of it is received into the groove in the under part. These two parts are so exactly fitted and gaged into one another (viz. the male gage marked *c* in fig. 2* into the female marked *g* in fig. 1*) that when the upper part of the mould is properly placed on, and in the under part of the mould, both together make the entire mould, and may be slid backwards for use so far, till the edge of either of the bodies on the middle of either carriage comes just to the edge of the female gages cut in each carriage: and they may be slid forward so far, till the bodies on either carriage touch each other: and the sliding of these two parts of the mould backwards makes the shank of the letter thicker, because the bodies on each part stand wider asunder; and the sliding them forwards makes the shank of the letter thinner, because the bodies on each part of the mould stand closer together. The parts of the mould are as follow: viz. a, The carriage. b, The body. c, The male gage. d e, The mouth piece. f, The register. g, The female gage. h h, The hag *a a a a*, The bottom plate. *b b b*, The wood on which the bottom plate lies. *c c c*, The mouth. *dd*, The throat. *e d d*, The pallet. *f*, The nick. *g g*, The stool. *h h*, The spring or bow.

Then the mould must be justified: and first the founder justifies the body, by casting about 20 proofs or samples of letters; which are set up in a composing stick, with all their nicks towards the right hand; and then, by comparing these with the pattern letters, set up in the same manner, he finds the exact measure of the body to be cast. He also tries if the two sides of the body are parallel, or that the body is no bigger at the head than at the foot, by taking half the number of his proofs and turning them with their heads to the feet of the other half; and if then the heads and the feet are found exactly even upon each other, and neither to drive out nor get in, the two sides may be pronounced parallel. He farther tries whether the two sides of the thickness of the letter are parallel, by first setting his proofs in the composing stick with their nicks upwards and then turning one half with their heads to the feet of the other half; and if the heads and feet lie exactly upon each other, and neither drive out nor get in, the two sides of the thickness are parallel.

The mould thus justified, the next business is to prepare the matrices. A matrice is a piece of brass or copper, of about an inch and a half long, and of a thickness in proportion to the size of the letter it is to contain. In this metal is sunk the face of the letter intended to be cast, by striking the letter-punch about the depth of an n. After this, the sides and face of the matrice must be justified and cleared with files, of all bunchings made by sinking the punch.

Every thing thus prepared, it is brought to the furnace; which is built of brick upright with four square sides, and a stone on the top, in which stone is a wide round hole for the pan to stand in. A foundry of any consequence has several of these furnaces in it.

As to the metal of which the types are to be cast, this, in extensive foundries, is always prepared in large quantities; but cast into small bars of about 20 pounds weight, to be delivered out to the workmen as occasion requires. In the letter-foundries, which have been long carried on with the greatest reputation we are informed, that a stock of metal is made up at two different times of the year, sufficient to serve the casters at the furnace for six months each time. For this purpose, a large furnace is built under a shade, furnished with a wheel vent, in order the more equally to heat the sides of a strong pot of cast iron, which holds, when full, 15 hundred-weight of the metal. The fire being kindled below, the bars of lead are let softly down into the pot, and their fusion promoted by throwing in some pitch and tallow, which soon inflame. An outer chimney which is built so as to project about a foot over the farthest lip of the pot, catches hold of the flame by a strong draught, and makes it act very powerfully in melting lead: whilst it serves at the same time to convey away all the fumes, &c. from the workmen to whom this laborious part of the business is committed. When the lead is thoroughly melted, a due proportion of the regulus of antimony and other ingredients is put in, and some more tallow is inflamed to make the whole incorporate sooner. The workmen now having mixed the contents of the pot very thoroughly by stirring long with a large iron ladle, next proceed to draw the metal off into the small troughs of cast iron, which are ranged to the number of fourscore upon a level platform faced with stone, built towards the right hand. In the course of a day, 15 hundred weight of metal can be easily prepared in his manner; and the operation is continued for as many days as are necessary to prepare a stock of metal of all the various degrees of hardness. After this, the whole is disposed into presses according to its quality, to be delivered out occasionally to the workmen.

The founder must now be provided with a ladle, which differs nothing from other iron ladles but in its size; and he is provided always with ladles of several sizes, which he uses according to the size of the letters he is to cast. Before the caster begins to cast, he must kindle his fire in the furnace to melt the metal in the pan. He therefore takes the pan out of the hole in the stone, and there lays in coals and kindles them; and, when they are well kindled, he sets the pan in again, and puts metal into it to melt; if it is a small-bodied letter he casts, or a thin letter of great bodies, his metal must be very hot; nay sometimes red-hot, to make the letter come. Then having chosen a ladle that will hold about so much as the letter and break is, he lays it at the toking-hole, where the flame bursts out, to heat. Then he ties a thin leather, cut with its narrow end against the face to the leather-groove of the matrice, by whipping a brown thread twice about the leather-groove, and fastening the thread with a knot. Then he puts both halves of the mould together, and puts the matrice into the matrice-cheek; and places the foot of the matrice on the stool of the mould, and the broad end of the leather upon the wood of the upper half of the mould, but not tight up, lest it might hinder the foot of the matrice from sinking close down upon the stool in a train of work. Then laying a little rosin on the upper wood of the mould, and having his casting-ladle hot, he with the boiling side of it melts the rosin: and, while it is yet melted, presses the broad end of the leather hard down on the wood, and so fastens it to the wood: all this is the preparation.

Now he comes to casting; in the performance of which, placing the under half of the mould in his left hand, with the hook or hag forward, he clutches the ends of its wood between the lower part of the ball of his thumb and his three hind fingers; then he lays the upper half of the mould upon the under half, so that the male gages may fall into the female gages, and at the same time the foot of the matrice places itself upon the stool; and, clasping his left-hand thumb strong over the upper half of the mould, he nimbly catches hold of the bow or spring with his right-hand fingers at the top of it, and his thumb under it, and places the point of it against the middle of the notch in the backside of the matrice, pressing it as well forwards towards the mould as downwards by the shoulder of the notch close upon the stool, while at the same time with his hinder fingers, he draws the under half of the mould towards he ball of his thumb, and thrusts by the ball of his thumb the upper part towards his fingers that both the registers of the mould may press against both sides of the matrice, and his thumb and fingers press both halves of the mould close together.

He then takes the handle of his ladle in his right hand, and with the ball of it gives a stroke, two or three, outwards upon the surface of the melted metal, to scum or clear it from the film or dust that may swim upon it; then takes up the ladle full of metal, and having his mould in his left hand, he a little twists the left side of his body from the furnace, and brings the geat of his ladle (full of metal) to the mouth of the mould, and twists the upper part of his right hand towards him to turn the metal into it, while at the same moment of time he jilts the mould in his left hand forwards, to receive the metal with a strong shake (as it is called), not only into the body of the mould, but while the metal is yet hot running, swift and strongly, into the very face of the matrice, to receive its perfect form there, as well as in the shank.

He then takes the upper half of the mould off the under half, by placing his right-hand thumb on the end of the wood next his left-hand thumb and his two middle-fingers at the other end of the wood: and finding the letter and break lie in the under half of the mould (as most commonly by reason of its weight it does), he throws or tosses the letter, break and all, upon a sheet of waste paper laid for that purpose on the bench, just a little beyond his left hand, and is then ready to cast another letter as before: and also, the whole number that is to be cast with that matrice. A workman will ordinarily cast about three thousand of these letters in a day.

When the casters at the furnace have got a sufficient number of types upon the tables, a set of boys come and nimbly break away the jets from them: the jets are thrown into the pots, and the types are carried away in parcels to other boys, who pass them swiftly under their fingers, defended by leather, upon smooth flat stones, in order to polish their broad-sides. This is a very dexterous operation, and is a remarkable instance of what may be effected by the power of habit and long practice; for these boys, in turning up the other side of the type, do it so quickly by a mere touch of the fingers of the left hand, as not to require the least perceptible intermission in the motion of the right hand upon the stone. The types, thus finely smoothened and flattened on the broad-sides, are next carried to another set of boys, who sit at a square table, two on each side, and there are ranged up on long rulers or sticks, fitted with a small projection, to hinder them from sliding off backwards. When the sticks are so filled, they are placed, two and two, upon a set of wooden pins fixed into the wall, near the dresser, sometimes to the amount of a hundred, in order to undergo the finishing operations. This workman, who is always the most expert and skilful in all the different branches carried on at the foundry, begins by taking one of these sticks, and, with a peculiar address, slides the whole column of types off upon the dressing-stick: this is made of well-seasoned mahogany, and furnished with two end-pieces of steel, a little lower than the body of the types, one of which is moveable, so as to approach the other by means of a long screw-pin, inserted in the end of the stick. The types are put into this stick with their faces next to the back or projection; and after they are adjusted to one another so as to stand even, they are then bound up, by screwing home the moveable end-piece. It is here where the great and requisite accuracy of the moulds comes to be perceived; for in this case the whole column, so bound up, lies flat and true upon the stick, the two extreme types being quite parallel, and the whole has the appearance of one solid continuous plate of metal. The least inaccuracy in the exact parallelism of the individual type, when multiplied so many times, would render it impossible to bind them up in this manner, by disposing them to rise or spring from the stick by the smallest pressure from the screw. Now, when lying so conveniently with the narrow edges uppermost, which cannot possibly be smoothed in the manner before mentioned by the stones, the workman does this more effectually by scraping the surface of the column with a thick-edged but sharp razor, which at every stroke brings on a very fine smooth skin, like polished silver; and thus he proceeds till in about half a minute he comes to the farther end of the stick. The other edges of the types are next turned upwards, and polished in the same manner. It is whilst the types thus lie in the dressing-stick, that the operation of bearding or barbing is performed, which is effected by running a plane, faced with steel, along the shoulder of the body next to the face; which takes more or less off the corner, as occasion may require. Whilst in the dressing-stick they are also grooved, which is a very material operation. In order to understand this, it must be remembered, that when the types are first broken off from the jets, some superfluous metal always remains, which would make them bear very unequally against the paper whilst under the printing-press, and effectually mar the impression. That all these inequalities may, therefore, be taken away, and that the bearings of every type may be regulated by the shoulders imparted to them all alike from the mould, the workman or dresser proceeds in the following manner: The types being screwed up in the stick as before mentioned with the jet end outermost, and projecting beyond the wood about one-eighth of an inch, the stick is put into an open press, so as to present the jet-end uppermost, and then every thing is made fast by driving a long wedge, which bears upon a slip of wood, which lies close to the types the whole length: then a plough or plane is applied, which is so constructed as to embrace the projecting part of the types betwixt its long sides, which are are made of polished iron. When the plane is thus applied, the steel cutter bearing upon that part between the shoulders of the types where the inequalities lie, the dresser dexterously glides it along, and by this means strips off every irregular part that comes in the way, and so makes an uniform groove the whole length, and leaves the two shoulders standing; by which means every type becomes precisely like to another, as to the height against paper. The types being now finished, the stick is taken out of the press, and the whole column replaced upon the other stick; and after the whole are so dressed, he proceeds to pick out the bad letters previous to putting them up into pages and papers. In doing this he takes the stick into his left hand, and turning the faces near to the light, he examines them carefully; and whenever an imperfect or damaged letter occurs, he nimbly plucks it out with a sharp bodkin, which he holds in the right hand for that purpose. Those letters which, from their form, project over the body of the type, and which cannot on this account be rubbed on the stones, are scraped on the broad-sides with a knife or file, and some of the metal next the face pared away with a pen-knife, in order to allow the type to come close to any other. This operation is called kerning.

The excellence of printing-types consists not only in the due performance of all the operations above described, but also in the hardness of the metal, form, and fine proportion of the character, and in the exact bearing and ranging of the letters in relation to one another. See Printing.

TYPHA, cat's-tail, a genus of plants of the classs monoecia, and order triandria; and in the natural system ranging under the 3d. order, calamariæ. The amentum of the male flower is cylindrical; the calyx is scarcely distinguishable; there is no corolla. The female has a cylindrical amentum below the male; the calyx is composed of villous hair; there is no corolla, and only one seed fixed on a capillary papus. There are two species, both natives of Britain; the latifolia and angustifolia. 1. Latifolia, great cat's-tail, or reed mace, is frequent in ponds and lakes. The stalk is six fet high; the leaves a yard long, hardly an inch wide, convex on one side: the amentum, or cylindrical club, which terminates the stalk, is about six inches long, of a dark-brown or fuscous colour. Cattle will sometimes eat the leaves, but Schreber thinks them noxious: the roots have sometimes been eaten in sallads, and the down of the amentum used to stuff cushions and mattresses. Linnæus informs us, that the leaves are used by the coopers in Sweden to bind the hoops of their casks. 2. Angustifolia, narrow-leaved cat's-tail, is found in pools and ditches. The leaves are semi-cylindrical, and the male and female spikes are remote and slender.

TYPOGRAPHY. See Printing.

U.

U, or V, the twentieth letter of our alphabet. In numerals V stands for five; and with a dash added at top, thus V̄, it signifies five thousand. In abbreviations, amongst the Romans, V. A. stood for Veterani assignati; V. B. viro bono; V. B. A. viri boni arbitratu; V. B. F. vir bonæ fidei; V. C. vir consularis; V. C. C. F. vale, conjux charissime, feliciter: V. D. D. voto dedicatur; V. G. verbi gratia; Vir. Ve. virgo vestalis; VL. videlicit; V. N. quinto nonarum.

VACATION, in law, is the whole time betwixt the end of one term and the beginning of another.

This word is also applied to the time from the death of a bishop, or other spiritual person, till the bishopric, or dignity, is supplied with another.

VACCINATION. Inoculation with the vaccine virus, for the purpose of securing against the infection of the small pox.

This subject cannot fail to "come home to the business and bosom" of every one; for where is the individual of such slender connection or limited sympathies, as to be indifferent to a question which "involves the lives annually of 40,000 in Britain alone," and of the same proportion throughout the civilized world?

It would be superfluous, then, to apologize for making the vaccine controversy a subject of separate and prominent disquisition.

We shall first lay before our readers a general history of the circumstances which led to the introduction of the new, as a substitute for the old, inoculation; we shall then enumerate the advantages which vaccination lays claim to, canvas the objections which have been made to the admission of such claims, and conclude by describing the general characteristics of perfect, and marks denoting spurious, cow-pock infection.

It is scarcely necessary to acquaint any reader by whom the first public proposal was made respecting the cow-pox inoculation. Dr. Jenner, while employed in the practice of surgery in a district of Gloucestershire, was surprized to find that many individuals whom he was called upon to inoculate, resisted every attempt to infect them with the small-pox virus. Upon enquiring into the occasion of this extraordinary immunity, he learnt that those in whom it existed had previously undergone a disease contracted by milking cows affected with a peculiar eruption on their teats. "It appeared (says Dr. Jenner) that this disease had been known among the dairy-maids from time immemorial, and that a vague opinion prevailed that it was a preventive of the small pox. This opinion I found was comparatively new among them; for all the old farmers declared they had no such idea in their early days: a circumstance which seemed easily accounted for, from my knowing that the common people were very rarely inoculated for the small pox, till that practice was rendered general by the improved method introduced by the Suttons; so that the working people in the dairies were seldom put to the test of the preventive power of the cow-pox." In prosecuting his enquiries, Dr. Jenner found it to be an unanimous opinion among medical practitioners in the neighbourhood, that the disease thus contracted from the cow was by no means to be relied on as a security against variolous infection; an opinion which he was at first concerned to find apparently well founded by the occurrence of the latter, in some individuals, who had been, as was imagined, subjected to the former.

This discouraging circumstance, although it damped the ardour of Dr. Jenner, did not occasion the abandonment of his investigation; and he was shortly gratified in ascertaining that the cow was subject to several varieties of eruption on her teats, all capable of producing ulcerations on the hands of the milkers, but not of insuring against the infection of small pox. This discovery removed the great obstacle to his interesting research, and our experimentalist was the first to distinguish and divide the genuine from the spurious cow-pox.

His expectations of success were a second time impaired, by finding that even among those who had been infected with the genuine virus, some were afterwards obnoxious to the small-pox contagion; and this difference of subsequent susceptibility was even witnessed in different individuals who had received the infection from the same animal.

It required no common share of perseverance still to abide by the object of pursuit after this seemingly almost insurmountable impediment to success. Dr. Jenner, however, was engaged in an undertaking of too much magnitude and moment to abandon it, unless from absolute necessity, and he still persisted.

It occurred to him that the specific properties of the cow-pock matter might vary with its progressive changes after secretion; and putting this likewise to the test of experiment, the result coincided with his conjecture, affording an explanation of this second anomaly equally clear and satisfactory with the former. He found, by repeated trials, that the genuine or preventive disease was only capable of being engendered by the matter from the ulcer in its earliest stages; that when from continuance it had undergone certain decompositions, it was no more capable of producing the true cow-pox than those eruptions of which we have already spoken. With these restrictions, Dr. Jenner found that the immunity from the variolous occasioned by the vaccine infection was for life; at least individuals without any effect were subjected to the former after the lapse of 15, 27, and even 50 years from the latter infection.

During this very curious and important investigation, Dr. Jenner was struck with the idea that the preventive he had discovered of small-pox contagion might be propagated from one individual to another in the manner of variolous inoculation; and for this supposition it does not seem improper to notice that he had, in one sense, the authority of analogy beyond that which could be claimed by the first ingrafters of variola; for the natural vaccine distemper is itself produced by a species of inoculation, which it is well known is by no means the case with the natural small pox.

We have stated this circumstance not from a desire to prejudge the question of the comparative merits of the variolous and vaccine inoculations. It is the duty of every one, it is ours especially and officially, to state arguments and facts as we find them, whether inimical to, or in favour of, either one or the other practice.

In pursuance of the plan we have above laid down, we now proceed to give as concentrated a view as possible of the superior advantages contended for by the advocates of inoculation for the cow-pox.

These we shall principally extract from a popular work on vaccinia, by Dr. Thornton, one of the most ardent and effective supporters and propagators of the new discovery.

1. It is maintained that the constitutional affection which cow-pox produces, is incomparably milder than that from variolous inoculation. The proportion of deaths from inoculated small pox is stated by Dr. Willan to be 1 in 250. "The zealous antivaccinists have denied it to be greater, under judicious treatment, than 1 in 1000." In the present, as in other instances, we leave the reader to select his own authority. We have only to add, that we believe the mortality at all of the vaccine distemper, in an immediate or direct manner, has not been contended for. This first proposition, then, in favour of the vaccine disease, is scarcely contested.

2. The cow-pox never disfigures the countenance. Of this, likewise, there is no dispute, as it refers to the distemper merely, independantly of the supposed consequences of it, which we are shortly to canvas.

3. The cow-pox may be introduced into the system without any apprehension of consequences, under circumstances which render even the inoculated small pox, in some measure, dangerous, such as the periods of teething, of pregnancy, and of advanced age. This proposition we believe to be likewise too well founded, and generally admitted to need substantiating by examples.

4. The cow-pox inoculation does not, like that of the small pox, disseminate the disease

it is not infectious. This is a most material circumstance in favour of the new inoculation. It is an undisputed fact that the mortality of small pox has increased since the adoption of the artificial mode of communicating it. Though many individuals have profited by inoculation, it has destroyed more lives, upon the whole, than it has preserved; and has aggravated the sufferings of those who have refused to employ it, in a greater degree than it has relieved those who have availed themselves of its protection.

5. The cow-pock does not leave any bad humours after it.

6. "Its security, as a prophylactic against the small pox, is equal to the small pox itself, either natural or inoculated." Thornton.

Under these six heads we believe that we have included all the benefits which are stated to have resulted from the Jennerian practice by its several advocates; and we apprehend it is only in the two last particulars that any material difference of sentiment now prevails. Even those who are still adverse to vaccine, as a substitute for small pox, inoculation, will allow that the dispute respecting the propriety or impropriety of the new practice, principally, if not entirely, hinges upon the validity or invalidity of the two last of the above propositions; for if we are to forego the advantages of Jenner's discovery, from an apprehension of an unjustifiable interference with the decrees of Providence, we should not only be compelled likewise to abandon variolous inoculation, but we ought no longer to think of arresting the progress of fever, of mitigating the violence of pain, or of extracting a carious tooth.

It is then the two last propositions which demand a separate and particular investigation.

First, Does the cow-pock engender other diseases? or, in the phraseology before used, does it leave any humours after it?

It is necessary to observe, that those gentlemen who have protested against vaccinia as introductory of other diseases, have described these affections to be principally cutaneous. Now those who aver that this is an absolute misrepresentation; and that so far from being followed by the alleged consequences, the number of scrophulous and cutaneous disorders which have followed upon the small pox, naturally and artificially introduced, are in a greater proportion than those which have happened posterior to vaccine inoculation; are much more numerous than the advocates for the contrary side of the question. On this ground, then, the inference from every principle of reasoning would be drawn by an impartial judgment in favour of vaccination. It will not, we hope, by the antivaccinist, be considered as irregular or unfair, to appeal on this head to a particular authority, viz. Dr. Willan, who, if he has no title to be considered as "the oracle of the metropolis in all cutaneous diseases," has unquestionably a right to speak on this head "as one having authority." This gentleman asserts that no new disorders have been introduced since the discovery of vaccination, and that the cutaneous affections which had been previously prevalent have in no measure increased in virulence. But Dr. Willan, it will perhaps be urged, may be a prejudiced, and therefore an incorrect, judge. Aware of the possibility of such objection to his statement, this physician has not given the detail of his own private practice merely in order to authorize his assertion, but has inserted in his treatise Dr. Bateman's extract from the register of patients at the public dispensary in London.

In the year 1797, before the publication of Dr. Jenner's enquiry, the total number of diseases was 1730; the number of chronic cutaneous eruptions was 85. In 1798, total number of diseases 1664; chronic cutaneous eruptions 82. In 1804 the proportions are 1915—89. In 1805, 1974—94. Nearly the same proportion, our author adds, may be deduced on comparing Dr. Murray's, Dr. Reid's, Dr. Walker's, and my own reports on diseases in London for the last ten years; and these, it may be added, were made without any reference to the vaccine controversy. Ought, then, the individual cases brought forward by the gentlemen opposed to vaccination to outweigh, or even balance, the contrary evidence above adduced? Here again we leave the reader to make his own inference.

If it should be urged that we have not brought forward the cases opposed to vaccinia, it is answered, neither have we adduced the more numerous instances which make against the variolous inoculation. In fact, the uncertainty of medical evidence forbids any satisfactory conclusion but that which is deduced from comparison on a large and general scale.

It would be, however, doing injustice to the cause of vaccination, to omit the following statements from Mr. Trye, surgeon to the Gloucester infirmary: 1st. "A more healthy description of human beings does not exist, nor one more free from chronic cutaneous impurities, than that which suffers most from cow-pox, by reason of their being employed in dairies.

2d. "The Gloucester infirmary, one of the largest provincial hospitals, is situated in a county in which accidental cow-pox has been prevalent from time immemorial: many hundreds among the labouring people have had the cow-pox since the establishment of that institution, and that more severely than is generally the case in artificial vaccination; and yet not a single patient in half a century has applied to the infirmary for relief of any disease, local or constitutional, which he or she imputed or pretended to trace to the cow-pox. And let it be repeated and remembered, that the artificial in no respect differs from the accidental cow-pox, except in being generally less virulent."

But the most momentous question still remains to be discussed. Does the cow-pock afford a permanent security against variolous infection?

Towards the decision of this point it will be found of essential consequence to revert to the two obstacles which we have already stated, as having presented themselves to Dr. Jenner in the commencement of his investigation.

While the reader retains this in mind, he will readily, we think, perceive the self-refutation contained in the following remarks of Dr. Rowley: "No other questions are admissible in vaccination than, Have the parties been inoculated for the cow-pox? Yes. Have they had the small pox afterwards? Yes. As to how, when, where, whether the cow-pox took, was genuine or spurious, or any arguments, however specious, as pretexts for doubts or failures, they are evasive or irrelative to the question. They may confound fools, but not heighten the credit of vaccination."

On this declaration it has been forcibly remarked, that "it would be little less absurd to tell a jury in a trial for murder, that the only question was, whether a pistol had been fired or not; and that it was of no consequence to inquire whether it was loaded with ball, or whether the sufferer had died of a pistol-shot."

After what we have already stated respecting those eruptions which had been indiscriminately thought the same as the true vaccine disease, and of the changes which the cow-pox matter is itself susceptible of, we think our readers will unite in opinion with us, that the questions respecting the genuine or spurious cow-pox, "the how, the when, and the where' the parties were inoculated, are most material points to ascertain, as preliminary steps to decision respecting alleged failures.

By the further statement which will be given in the sequel, it will be perceived that there are several circumstances necessary to the perfection and absolutely preventive power of vaccine inoculation, which it is by no means unfair to suppose were overlooked by, or unknown to, the inoculators at the early periods of the practice. "During the years 1799 and 1800, vaccine inoculation was performed by ten or twelve thousand persons who had never seen the vaccine pustule." (Dr. Willan.) Now, under these circumstances, we cannot help agreeing with this author that it is rather matter of surprise that the number of unsuccessful cases has proved so comparatively small.

Here it is material to observe, that the majority of those examples which have been brought forward as examples of variolous, after vaccine disease, have been attended with so much irregularity, that they cannot be considered as genuine cases of small pox. This, we think, has been rendered evident by the very able and dispassionate examination of Dr. Willan on the progress and termination of the most formidable of such cases as have occurred in and about the metropolis.

But let it be granted to the opposer of vaccination, that several instances have been presented of perfect and regular small pox subsequent to the vaccine disease, equally genuine and regular, "yet still the Jennerian practice must maintain its ground triumphantly, if it can be shewn to be *as effectual* a preventive of small pox as the old inoculation. Now we think it has been demonstrated beyond the possibility of contradiction, that the number of authenticated cases of small pox after the old inoculation, and even after a former attack of the natural disease, are more numerous in proportion than those that are alleged with any probability of such an occurrence after complete vaccination." The writer of the article from which we have extracted the above observations, goes on to say: "On the whole, we think there are not fewer than twenty distinct cases of small pox, occurring a second time in the same subject, each of them authenticated far more completely than any one that has been cited by the adversaries of vaccination. We are persuaded, indeed, that we shall be supported by every impartial person who makes himself master of the whole evidence, in saying, that there are not so many as ten cases of small pox, after perfect vaccination, proved in such a way as to be entitled to any sort of attention. Now the medical council, consisting of almost all the great practitioners in London, have reported that 'nearly as many persons have been already vaccinated in this kingdom, as were ever inoculated for the small pox since the first introduction of that practice; so that if the two cases were exactly upon a footing, the risk of failure seems to be at least twice as great in the small-pox inoculation as in that for the cow-pox.' And yet who is there in the present day who thinks for a moment of alleging possible insecurity as an argument against variolous inoculation? It may be instructive to state that this argument was however used against the old at the time of its introduction, and urged much in the same spirit as it now is against the new. Dr. Willan and others, in their respective treatises, have cited many examples of the mode in which the variolous controversy was carried on, a single one of which our limits will only permit us to extract.

"I fear they may be accounted physicians of no value and forgers of lies, who so confidently tell us what it is impossible for them to know, namely, that they who undergo their experiment (the inoculation for small pox) are for ever thereby secured from any future danger of infection." Page 18, Rev. Mr. Massey's sermon against the dangerous and sinful practice of inoculation.

Against the suggestion of Mr. Goldson, that, although the natural cow-pox may secure from variolous infection, the inoculated disease may be more precarious and uncertain, we think it of consequence to notice in the first place, that were the variolous and vaccine inoculation to be judged and compared a priori upon the ground of analogy alone, the latter would have the fairest pretensions to public confidence. The natural and the inoculated cow-pox, we have already said, are ingrafted upon the system in nearly a similar manner; in the instance of variolous infection, this is not the case. Further, the vaccine matter, whether taken directly from the cow, or from the arm of an inoculated person, produces an affection which is not so generally dissimilar as the ingrafted and naturally received small pox; what authority then have we for inferring that the virus undergoes that specific change in the human body, which the theory of Mr. Goldson supposes? If then permanence of security is allowed to the natural (and the admission of this, from a man of such ability and candour as Mr. Goldson, is exceedingly material), we cannot but suppose it repugnant to every principle of analogy, to deny it to the inoculated cow-pox.

It is necessary to remark, that the cases which have been collected and recorded, do by no means serve to strengthen the suspicion of immunity for a given time; for the utmost irregularity has been shewn, with respect to the period of variolous subsequent to vaccine infection. "The cases," says Dr. Willan, "which I have adduced of variolous eruption, took place without any certain order, from five months to seven years after vaccination. If it is said that the preventive power of the cow-pox ceases in some persons at the end of a month or two, while in others it lasts sixty or seventy years, according to the varieties of constitution, the assertion is too vague to admit of an answer."

The inoculated small pox, when first introduced, was limited like the vaccine; first to two, afterwards to three, and then to four years; but experience has fully established the falsity of these assumptions, and the most determined sceptic no longer talks of temporary immunity from variolous inoculation.

To urge the argument further against the doctrine of partial and limited security, would be, we think, superfluous; unsupported by analogy, and unsustained by fact, it falls mole suâ.

We now proceed to extract from Dr. Willan's treatise the characteristics of perfect, and marks of spurious, vaccination.

"Vaccination," says our author, "is accounted perfect, when recent lymph has been carefully inserted beneath the cuticle, in a person free from any contagious disorder; and has produced a semitransparent pearl-coloured vesicle, which, after the ninth day, is surrounded by a red areola, and afterwards terminates in a hard dark-coloured scab. The form and structure of this vesicle are peculiar; its base is circular, or somewhat oval, with a diameter of about four lines on the tenth day. Till the end of the eighth day, its upper surface is uneven, being considerably more elevated at the margin than about the centre, and sometimes indented by one or two concentric furrows; but on the ninth or tenth day, the surface becomes plane, and in a very few instances, the central part is highest. The margin is turgid, firm, shining, and rounded so as often to extend a little beyond the line of the base.

"The vesicle consists internally of numerous little cells, filled with clear lymph, and communicating with each other. The areola, which is formed round the vesicle, is of an intense red colour. Its diameter differs in different persons, from a quarter of an inch to two inches, and it is usually attended with a considerable tumour and hardness of the adjoining cellular membrane. On the eleventh and twelfth day, as the areola declines, the surface of the vesicle becomes brown in the centre, and less clear at the margins. The cuticle then begins to separate, and the fluid in the cells gradually concretes into a hard rounded scab of a reddish-brown colour. The scab becomes at length black, contracted, and dry, but it is not detached until after the twentieth day from the inoculation. It leaves a permanent circular cicatrix, about five lines in diameter, and a little depressed, the surface being marked with very minute pits or indentations, denoting the number of cells, of which the vesicle has been composed."

Such are the general characteristics of perfect vaccination. "Imperfect vaccination is not characterised by any uniform sign or criterion, but exhibits in different cases very different appearances, as pustules, ulcerations, or vesicles of an irregular form. The vaccine pustule is conoidal; it increases rapidly from the second to the fifth or sixth day, when it is raised on a hard inflamed base, with diffuse redness extending beyond it on the skin. It is usually broken before the end of the sixth day, and is soon after succeeded by an irregular yellowish-brown scab. The redness disappears in a day or two, and the tumour gradually subsides.

"Vaccination is imperfect or insufficient, 1. When the fluid employed has lost some of its original properties. 2. When the persons inoculated were soon afterwards affected with any contagious fever. 3. When they are affected at the time of inoculation, with some chronic cutaneous disorders.

"1. The qualities of the vaccine fluid are altered, soon after the appearance of an inflamed areola round the vesicle; and the fluid, although taken out of a vesicle in the best possible state, may be injured by heat, exposure to air, rust, moisture, and other causes.

"When scales are formed over variolous pustules, and vaccine vesicles, the matter they afford is often acrid and putrescent; and if inoculated, it perhaps neither communicates the vaccine pock nor the small pox, but produces a fatal disease, with symptoms similar to those which arise from slight wounds received in dissecting putrid bodies. Should the pustules remain entire till the twentieth day of eruption, matter taken from them, even at that period, will sometimes communicate the disease in its usual form, though perhaps with considerable virulence. We are, however, now assured on good authority, that matter improperly kept, or the thick matter from collapsed and scabbing variolous pustules, and used for the purpose of inoculation, does not always produce the small pox, nor prevent the future occurrence of that disease, although the persons inoculated may have had inflammation and suppuration of the arm, and pains in the axilla, with fever and eruptions on the ninth or tenth day. In like manner, if the vaccine fluid employed is taken at a late period, as from the twelfth to the eighteenth day, it does not always produce the genuine cellular vesicle, but is in some cases wholly inefficient, while in others it suddenly excites a pustule or ulceration, in others an irregular vesicle, and in others erysipelas. Failures may have been occasioned by repeatedly puncturing or draining the vesicle, on two or three successive days.

"2. Eruptive fevers, and other febrile diseases, interfere with the progress of the vaccine vesicle. The measles, scarlatina, varicella, typhus, and influenza, appearing soon after vaccination, either render it ineffective, or suspend the action of the virus.

"3. The cutaneous diseases which sometimes impede the formation of the genuine vaccine vesicle, are herpes (including the shingles, and vesicular ring-worm), the dry and the humid tetter, and the lichen; but especially the porrigo (or tinea), comprising the varieties denominated crusta-lactea, area, achores, and favi, all of which are contagious. To these should perhaps be added the itch and prurigo."

"The right inference," our author in another part of his treatise observes, "from the mistakes or failures, and from the nicety of vaccine inoculation, is, that those only should be inoculators, who have had a sufficient education, and who have particularly attended to the subject of vaccination." Dr. Willan then goes on to enforce the propriety of a strict examination, and in dubious cases a reinoculation, of those persons especially who were inoculated between the 1st of January, 1799, and the 1st of January, 1802.

We are under the necessity of stating, that in the present article we have appealed principally to the authority of Dr. Willan, not merely on account of the intrinsic and universally acknowledged value of such authority; but because this gentleman, being neither an inoculator nor a partisan, cannot fail to be acquitted even by those who are least disposed to liberality of sentiment, of being in any measure influenced by the motives charged upon vaccinators in the following sentences, which, the reader will be surprised to find, are the composition of a learned, sagacious, and most respectable physician:

"The cow-pox inoculators who have been principals, reproach one another as not having the genuine matter, or skilful management, of vaccination; each says his brother-labourers in the same vineyard are wrong. If the small pox happens after Peter's operation, James, Paul, and John, are not at all surprised; if from James, Paul, or John, disasters happen, Peter says it is what he expected. Each pretends to some superior mystery over his brother-vaccinator. Each leader seems to say,—Come to my shop; this is the only true booth in the fair: that the new one—this is the only true one." (Dr. Moseley.)

It would be unjust to conclude without admitting the only shadow of justification, which such language can claim; namely, the equal and perhaps prior interference of medical writers, on the opposite side of the question. We cannot forget the mode in which Mr. Goldson's first candid and dispassionate inquiry into the merits of vaccination, was replied to by some of the vaccinators. Surely party rancour ought at least to be excluded from this subject of universal interest.

VACCINIUM, the WHORTLE-BERRY, or BILBERRY, a genus of plants of the class octandria, and order monogynia; and arranged in the natural system under the 18th order, bicornes. The calyx is superior; the corolla monopetalous: the filaments inserted into the receptacle; the berry quadrilocular and polyspermous. There are 27 species, the most remarkable of which are: 1. The myrtilus, black-whorts, whortle-berries, or bilberries, growing in woods and on heaths abundantly. The flowers frequently vary, with five segments at the rim, and with ten stamina. The berries when ripe are of a bluish-black colour, but a singular variety, with white berries, was discovered by the duke of Athol, growing in the woods about mid-way between his two seats of Dunkeld and Blair. The berries have an astringent quality. In Arran and the Western Isles they are given in diarrhœas and dysenteries with good effect. The Highlanders frequently eat them in milk, which is a cooling agreeable food; and sometimes they make them into tarts and jellies, which last they mix with whisky, to give it a relish to strangers. They dye a violet-colour; but it requires to be fixed with alum. The grouse feed upon them in the autumn. 2. The uliginosum, or great bilberry-bush, is found in low moist grounds, and almost at the summits of the Highland mountains. The leaves are full of veins, smooth and glaucous, especially on the under side; the berries are eatable, but not so much esteemed as the preceding; as they are apt, if eaten in any quantity, to give the head-ache. 3. The vitis idæa, or red whortle-berries, frequent in dry places, in heaths, woods, and on mountains. The berries have an acid cooling quality, useful to quench the thirst in fevers. The Swedes are very fond of them made into the form of a rob or jelly, which they eat with their meat as an agreeable acid, proper to correct the animal alkali. 4. The oxycoccus, cranberries, moss-berries, or moor-berries, frequent on peat-bogs. The stalks are long, slender, woody, weak, and trailing; the leaves are stiff, acutely oval, glaucous underneath, their edges turned back, and growing alternate; two or three flowers grow singly on long red footstalks out of the extremity of the branches; the flowers are red, divided deeply into four acute segments, which are reflexed quite backwards; the filaments are downy; the antheræ ferruginous, and longer than the filaments; the berries red, and about the size of the hawthorn-berries. At Long-town, on the borders of Cumberland, they are made so considerable an article of commerce, that at the season when they are ripe, not less than 20*l.* or 30*l.*'s worth are sold by the poor people each market-day for five or six weeks together, which are afterwards dispersed over different parts of the kingdom for making the well-known cranberry-tarts.

VAGINA. See ANATOMY.

VAGINALIS, a genus of birds of the order grallæ: the generic character is, bill strong, thick, conic-convex, compressed; the upper mandible covered above with a moveable horny sheath; nostrils small, placed before the sheath; tongue above round, beneath flattened, pointed at the tip; face naked, papillous; wings with an obtuse excrescence under the flexure; legs strong, four-toed, naked a little above the knees; toes rough beneath, claws grooved. There is but a single species, which inhabits New Zealand and the South Sea islands, from 15 to 18 inches long, and feeding on shell-fish.

VAGRANTS are divided into three classes: 1st. Idle and disorderly persons. These, as described by the vagrant-act, consist of those who threaten to run away and leave their wives and children to the parish. All persons returning to a parish whence they have been legally removed, without bringing a certificate from the parish to which they belong. All who, not having wherewith to maintain themselves, refuse to work. All who beg alms from door to door, or in the streets and highways. Likewise those who, not using proper means to get employment, or possessing ability to work, refuse to do it; or spend money in alehouses, or in any improper manner; and by not employing a proper proportion of their earnings towards the maintenance of their families, suffer them to become chargeable to the parish. The punishment for these offences is a commitment to the house of correction, and hard labour, for any definite time not exceeding a month; the time must be set forth in the warrant of commitment, which must al o shew the authority of the person committing. The commitment must be in execution, that is to say, for punishment; and being so, the justice must make a record of the conviction, and transmit the same to the sessions. Any person may apprehend and carry such persons before a magistrate; and if they resist or escape, they shall be punished as rogues and vagabonds: the reward for such apprehension is 5*s.*, to be paid by the overseer of the parish.

2. Rogues and vagabonds. No infant under the age of seven years can be called a rogue and vagabond, but shall be removed to its place of settlement, like other paupers.

The following is a list of those who are deemed rogues and vagabonds: All persons gathering alms under pretended losses; persons going about as collectors for prisons or hospitals; fencers; bearwards; common players not legally authorised; minstrels; jugglers; real or pretended gypsies; fortune-tellers; any persons using any subtle craft to impose upon any of his majesty's subjects, or playing at unlawful games, or any who have run away and left their wives and children a charge to the parish; all petty chapmen and pedlars not authorised by law; all persons not giving a good account of themselves; all beggars pretending to be soldiers or seamen, or pretending to go to work in harvest; or illegal dealers in lottery tickets and shares. And all other persons wandering abroad and begging, shall be deemed rogues and vagabonds; the reward for apprehending such persons is 10*s.*, to be paid by the high constable, on an order from the justice. There is a penalty of 10*s.* on a constable who refuses or neglects to apprehend them.

3. Incorrigible rogues, are all end-gatherers, offending against the stat. 13 Geo.; which is collecting, buying, receiving, or carrying, any ends of yarn, wefts, thrums, short yarn, or other refuse of cloth or woollen goods. All persons apprehended as rogues and vagabonds, and escaping, or refusing to go before a justice, or refusing to be conducted by the pass, or giving a false account of themselves on examination, after warning. All rogues or vagabonds escaping from the house of correction before the expiration of the time of their commitment; and all who have been punished as rogues and vagabonds, and repeat the offence.

There is by 17 Geo. II. c. 25, a privy search appointed; and the justices or two of them four times a year at least meet, and command the constables of every ward or parish, properly assisted, to make a general search in one night, and cause all vagrants that shall be found on such search to be brought before a justice; and two justices, in case such person is charged as a vagrant, or on suspicion of felony, may examine him; and if he cannot shew some lawful way of getting his livelihood, or procure bail for his reappearance, may commit him for a certain time not exceeding six days; and if, after advertising his person, and any thing about him suspected to be stolen, no accusation is brought, he shall be discharged or dealt with according to law. All rogues and vagabonds are examined upon oath as to their parish, and the written examination signed by them and the justice, and transmitted to the sessions.

The punishment is public whipping, or confinement to the house of correction till the next sessions, or any less time; and if at the sessions the court adjudge such person a rogue and vagabond, or an incorrigible rogue, they may order such rogue or vagabond to the house of correction and hard labour for six months, or such incorrigible rogue for not less than six months or more than two years, and during his confinement to be whipped as they shall think fit. And if such rogue or vagabond is a male above 12 years old, the court may, after his confinement, send him to be employed in his majesty's service: and if such incorrigible rogue shall make his escape, or offend a second time, he shall be transported for seven years. After such whipping or confinement, the justice may, by a pass under his hand (of which a duplicate shall be filed at the next sessions), cause him to be conveyed to the place of his last legal residence, and if that cannot be found, to the place of his birth; and if they are under fourteen years of age, and have parents living, then to the place of their abode; and the parish to which the vagrant shall be conveyed, shall employ him in some workhouse till he gets some employment; and if he refuses to work, he shall be sent to the house of correction and hard labour.

The general tenor of the laws respecting vagrants, is extremely severe, and very justly so; and it is the duty of every justice of the peace to keep his district free from this class, as they are great burthens to the parish, and very difficult to be removed. For the best account of the vagrant-act, vide Burn's Justice, vol. 4, article Vagrant.

VAHLIA, a genus of plants of the class and order pentandria digynia. The calyx is five-leaved; corolla five-petalled; capsule inferior, one-celled, many-seeded. There is one species, a herb of the Cape.

VALANTIA, a genus of plants in the order monœcia, of the class polygamia, and in the natural system arranged under the 41st order, the asperifoliæ. There is scarcely any calyx; the corolla is monopetalous, flat, four-parted; the stamina four, with small antheræ; the hermaphrodite flowers have a pistillum with a large germen, a bifid style the length of the calyx, and one seed; the pistilla of the male flowers are hardly discernible. There are 9 species, only one of which is a native of Britain, the cruciata; the stalks of which are square, the whole plant hairy, the leaves oval and verticillate, four in a whorl; the flowers are yellow, and grow on short peduncles out of the alæ of the leaves. The roots, like those of the galium, to which it is nearly related, will dye red. It is astringent, and was once used as a vulnerary.

VALENTINIANS, in church history, a sect of christian heretics, who sprung up in the second century, and were so called from their leader Valentinus. The valentinians were only a branch of the gnostics, who realized or personified the Platonic ideas concerning the Deity, whom they called Pleroma, or plenitude. Their system was this: the first principle is Bythos, *i.e.* depth, which remained many ages unknown, having with it Ennoe, or thought, and Sige, or silence; from these sprung the Nous, or intelligence, which is the only son, equal to, and alone capable of comprehending, the Bythos; the sister of Nous they called Aletheia, or truth; and these constituted the first quaternity of æons, which were the source and original of all the rest; for Nous and Aletheia produced the world and life, and from these two proceeded man and the church. But besides these eight principal æons, there were twenty-two more, the last of which, called Sophia, being desirous to arrive at the knowledge of Bythos, gave herself a great deal of uneasiness, which created in her anger and fear, of which was born matter. But the Horos, or bounder, stopped her, preserved her in the Pleroma, and restored her to perfection. Sophia then produced the Christ and the Holy Spirit, which brought the æons to their last perfection, and made every one of them contribute their utmost to form the Saviour. Her Enthymese, or thought, dwelling near the Pleroma, perfected by the Christ, produced every thing that is in the world, by its divers passions. The Christ sent into it the Saviour, accompanied with angels, who delivered it from its passions, without annihilating it; and thence was formed corporeal matter.

VALERIANA, a genus of plants, of the class triandria and order monogynia, and in the natural system arranged under the 48th order, aggregatæ. There is hardly any calyx; the corolla is monopetalous, gibbous at the base, situated above the germen; there is only one seed. There are 31 species, only four of which are natives of Britain, the officinalis, the olitoria, the rubra, and the dioica; of these only the officinalis is useful. The root of this plant is perennial; the stalk is upright, smooth, channelled, round, branched, and rises from two to four feet in height; the leaves on the stem are placed in pairs upon short broad sheaths; they are composed of several lance-shaped, partially dentated, veined, smooth pinnæ, with an odd one at the end, which is the largest; the floral leaves are spear-shaped and pointed; the flowers are small, of a white or purplish colour, and terminate the stem and branches in large bunches. It flowers in June, and commonly grows about hedges and woods.

It is supposed to be the φυ of Dioscorides and Galen, by whom it is mentioned as an aromatic and diuretic: it was first brought into estimation in convulsive affections by Fabius Columna, who relates that he cured himself of an epilepsy by the root of this plant; we are told, however, that Columna suffered a relapse of the disorder; and no further accounts of the efficacy of valerian in epilepsy followed till those published by Dominicus Panarolus fifty years afterwards, in which three cases of its success are given.

The advantages said to be derived from this root in epilepsy, caused it to be tried in several other complaints termed nervous, particularly those produced by increased mobility and irritability of the nervous system, in which it has been found highly serviceable. Bergius states its virtues to be antispasmodic, diaphoretic, emmenagogue, diuretic, anthelmintic. The root in substance is most effectual, and is usually given in powder from a scruple to a drachm; its unpleasant flavour may be concealed by a small addition of mace. A tincture of valerian in proof spirit and in volatile spirit is ordered in the London Pharmacopœia. Cats are very fond of the smell of this root, and seem to be intoxicated by it.

VALLISNERIA, in botany, a genus of the diœcia diandria class of plants, with a monopetalous tripartite flower; its fruit is a long, cylindraceous, and unilocular capsule, containing numerous oval seeds. There are two species.

VALVE, in hydraulics, pneumatics, &c. is a kind of lid or cover to a tube, vessel, or orifice, contrived to open one way; but which, the more forcibly it is pressed the other way, the closer it shuts the aperture, like the clapper of a bellows: so that it either admits the entrance of a fluid into the tube, or vessel, and prevents its return; or permits it to escape, and prevents its re-entrance.

Valves are of great use in the air-pump, and other wind-machines; in which they are usually made of pieces of bladder. In hydraulic engines, as the emboli or suckers of pumps, they are mostly of strong leather, of a round figure, and fitted to shut the apertures of the barrels or pipes. Sometimes they are made of two round pieces of leather enclosed between two others of brass; having divers perforations, which are covered with another piece of brass, moveable upwards and downwards, on a kind of axis, which goes through the middle of them all. Sometimes they are made of brass, covered over with leather, and furnished with a fine spring, which gives way upon a force applied against it; but upon the ceasing of that, returns the valve over the aperture. See Pump, and Hydrostatics.

Valve, in anatomy, a thin membrane applied on several cavities and vessels of the body, to afford a passage to certain humours going one way, and prevent their reflux towards the place whence they came.

VAN, Vant, or Vaunt, a term derived from the French avant, or avaunt, signifying before, or foremost of any thing; thus we say, the van-guard of an army, &c.

Van, in sea-language, denotes the foremost division of any naval armament, or the part that usually leads the way to battle, or advances first in the order of sailing.

VANDELLIA, a genus of plants of the class didynamia and order angiospermia. The calyx is quadrifid; the corolla ringent; the two exterior filaments proceed from the disc of the lip of the corolla; the antheræ are connected; the capsule is unilocular and polyspermous. There are only two species known, the diffusa and pratensis.

VANE, in a ship, &c. a thin slip of some kind of matter, placed on high in the open air, turning easily round on an axis or spindle, and veered about by the wind, to shew its direction or course.

Vanes, in mathematical or philosophical instruments, are sights made to slide and move upon cross-staves, fore-staves, quadrants, &c.

VANGNESIA, a genus of plants of the class and order pentandria monogynia. The calyx is five-toothed; corolla, tube globular, with a hairy throat; stigma bilamellate; berry inferior, four or five-seeded. There is one species, a tree of China.

VANILLA. See Epidendrum.

VAPOUR. See Evaporation, and Fluidity.

VARIABLE, in geometry and analytics, is a term applied by mathematicians to such quantities as are considered in a variable or changeable state, either increasing or decreasing. Thus the abscisses and ordinates of an ellipsis, or other curve line, are variable quantities; because they vary or change their magnitude together, the one at the same time with the other. But some quantities may be variable by themselves alone, or while those connected with them are constant; as the abscisses of a parallelogram, whose ordinates may be considered as all equal, and therefore constant. Also the diameter of a circle, and the parameter of a conic section, are constant, while their abscisses are variable.

Variable quantities are usually denoted by the last letters of the alphabet, z, y, x, &c.; while the constant ones are denoted by the leading letters, a, b, c, &c.

Some authors, instead of variable and constant quantities, use the terms fluent and stable quantities.

The indefinitely small quantity by which a variable quantity is continually increased or decreased in very small portions of time, is called the differential, or increment or decrement. And the rate of its increase or decrease at any point, is called its fluxion; while the variable quantity itself is called the fluent. And the calculation of these, is the subject of the new methodus differentialis, or doctrine of fluxions.

VARIANCE, in law, signifies any alteration of a thing formerly laid in a plea; or where the declaration in a cause differs from the writ, or from the deed upon which it is grounded. 2 Lit. Abr. 629.

If there is a variance between the declaration and the writ, it is error, and the writ shall abate. And if there appears to be a material variance between the matter pleaded, and the manner of pleading it, this is not a good plea; for the manner and matter of pleading ought to agree in substance, or there will be no certainty in it. Cro. Jac. 479.

VARIATION, in geography and navigation, is the deviation of the magnetical needle, in the mariner's compass, from the true north point, towards either the east or west; or it is an arch of the horizon, intercepted between the meridian of the place of observation and the magnetic meridian. See MAGNETISM.

VARIATION, in astronomy. The variation of the moon, called by Bulliald the reflection of her light, is the third inequality observed in the moon's motion; by which, when out of the quadratures, her true place differs from her place twice equated. See ASTRONOMY.

Newton makes the moon's variation to arise partly from the form of her orbit, which is an ellipsis; and partly from the inequality of the spaces which the moon describes in equal times, by a radius drawn to the earth.

To find the greatest variation. Observe the moon's longitude in the octants; and to the time of observation compute the moon's place twice equated; then the difference between the computed and observed place, is the greatest variation.

Tycho makes the greatest variation 40′ 30″; and Kepler makes it 51′ 49″. But Newton makes the greatest variation, at a mean distance between the sun and the earth, to be 35′ 10″; at the other distances, the greatest variation is in a ratio compounded of the duplicate ratio of the times of the moon's synodical revolution directly, and the triplicate ratio of the distance of the sun from the earth inversely. And therefore in the sun's apogee, the greatest variation is 33′ 14″, and in his perigee 37′ 11″; provided that the eccentricity of the sun is to the transverse semidiameter of the orbis magnus, as 16 $\frac{15}{16}$ to 1000. Or, taking the mean motions of the moon from the sun, as they are stated in Dr. Halley's tables, then the greatest variation at the mean distance of the earth from the sun will be 35′ 7″, in the apogee of the sun 33′ 27″, and in his perigee 36′ 51″.

VARIATION *of curvature*, in geometry, is used for that inequality or change which takes place in the curvature of all curves except the circle, by which their curvature is more or less in different parts of them. And this variation constitutes the quality of the curvature of any line.

Sir Isaac Newton makes the index of the inequality, or variation of curvature, to be the ratio of the fluxion of the radius of curvature to the fluxion of the curve itself: and Maclaurin, to avoid the perplexity that different notions, connected with the same terms, occasions to learners, has adopted the same definition; but he suggests, that this ratio gives rather the variation of the ray of curvature, and that it might have been proper to have measured the variation of curvature rather by the ratio of the fluxion of the curvature itself to the fluxion of the curve; so that, the curvature being inversely as the radius of curvature, and consequently its fluxion as the fluxion of the radius itself directly, and the square of the radius inversely, its variation would have been directly as the measure of it according to Newton's definition, and inversely as the square of the radius of curvature.

According to this notion, it would have been measured by the angle of contact contained by the curve and circle of curvature, in the same manner as the curvature itself is measured by the angle of contact contained by the curve and tangent. The reason of this remark may appear from this example: The variation of curvature, according to Newton's explication, is uniform in the logarithmic spiral, the fluxion of the radius of curvature in this figure being always in the same ratio to the fluxion of the curve; and yet, while the spiral is produced, though its curvature decreases, it never vanishes; which must appear a strange paradox to those who do not attend to the import of sir Isaac Newton's definition.

The variation of curvature at any point of a conic section, is always as the tangent of the angle contained by the diameter that passes through the point of contact, and the perpendicular to the curve at the same point; or to the angle formed by the diameter of the section, and of the circle of curvature. Hence the variation of curvature vanishes at the extremities of either axis, and is greatest when the acute angle, contained by the diameter passing through the point of contact and the tangent, is least.

When the conic section is a parabola, the variation is as the tangent of the angle, contained by the right line drawn from the point of contact to the focus, and the perpendicular to the curve. See CURVATURE.

From sir Isaac Newton's definition may be derived practical rules for the variation of curvature, as follows:

1. Find the radius of curvature, or rather its fluxion: then divide this fluxion by the fluxion of the curve, and the quotient will give the variation of curvature; exterminating the fluxions when necessary, by the equation of the curve, or perhaps by expressing their ratio by help of the tangent, or ordinate, or subnormal, &c.

2. Since $\frac{\dot{z}^3}{-\dot{x}\ddot{y}}$, or $\frac{\dot{z}^3}{-\ddot{y}}$ (putting $\dot{x}=1$) denotes the radius of curvature of any curve z, whose absciss is x, and ordinate y, if the fluxion of this is divided by $\dot{z}$, and $\dot{z}$ and $\ddot{z}$ are exterminated, the general value of the variation will come out $\frac{-3\dot{y}\ddot{y}^2+\dddot{y}(1+\dot{y}^2)}{\ddot{y}^2}$; then, substituting the values of $\dot{y}$, $\ddot{y}$, $\dddot{y}$ (found from the equation of the curve) into this quantity, it will give the variation sought.

Ex. Let the curve be the parabola, whose equation is $ax=y^2$. Here then $2y\dot{y}=a\dot{x}=a$, and $\dot{y}=\frac{a}{2y}$; hence $\ddot{y}=\frac{-a\dot{y}}{2yy}=\frac{-aa}{4y^3}$, and $\dddot{y}=\frac{-3aa\dot{y}}{2y^4}=\frac{3a^3}{8y^5}$. Therefore

$$\frac{-3\dot{y}\ddot{y}^2+\dddot{y}(1+\dot{y}^2)}{\ddot{y}^2}=-3\dot{y}+\dddot{y}\times\frac{1+\dot{y}^2}{\ddot{y}^2}$$

$$=\frac{-3a}{2y}+\frac{3a^3}{8y^5}\times\left(1+\frac{aa}{4yy}\right)\times\frac{16y^6}{a^4}=\frac{6y}{a},$$

the variation sought.

VARIOLÆ, the small-pox, in medicine. See MEDICINE, and VACCINATION.

VARNISH, a thick, viscid, shining liquor, used by painters, gilders, and various other artificers, to give a gloss and lustre to their works; as also to defend them from the weather, dust, &c. See RESINS.

A coat of varnish ought to possess the following properties: 1. It must exclude the action of the air; because wood and metals are varnished to defend them from decay and rust. 2. It must resist water; for otherwise the effect of the varnish could not be permanent. 3. It ought not to alter such colours as are intended to be preserved by this means. It is necessary, therefore, that a varnish should be easily extended or spread over the surface, without leaving pores or cavities, that it should not crack or scale, and that it should resist water.

Resins are the only bodies that possess these properties, consequently they must form the basis of every varnish. For this purpose, they must be dissolved, as minutely divided as possible, and combined in such a manner, that the imperfections of those that might be disposed to scale, may be corrected by others.

Resins may be dissolved by three agents: 1. by fixed, or fat oil; 2. by volatile, or essential oil; 3. by spirit of wine. Accordingly we have three kinds of varnish; fat or oily varnish, essential oil varnish, and spirit varnish.

These agents are of such a nature as either to dry up and become hard, or to evaporate and fly off, leaving the resin fixed behind.

Varnishes should be carefully kept from dust, and in very clean vessels; they should be laid as thin and even as possible with a large flat brush, taking care to lay the strokes all one way. A warm room is best for varnishing in, as cold chills the varnish, and prevents it from lying even.

Varnishes are polished with pumice-stone and tripoli. The pumice-stone must be reduced to a very fine powder, and put upon a piece of serge moistened with water; with this the varnished substance is to be rubbed equally and lightly. The tripoli must also be reduced to a fine powder, and put upon a clean woollen cloth moistened with olive-oil, with which the polishing is to be performed. The varnish is then to be wiped with soft linen, and, when quite dry, cleaned with starch, or Spanish white, and rubbed with the palm of the hand, or with a linen cloth.

Fat oil varnish. Fixed, or fat oil, will not evaporate; nor will it become dry of itself. To make it dry, it must be boiled with metallic calces or oxides. Litharge is generally used for this purpose. Oil so prepared is called drying-oil. To accelerate the drying of oil varnish, oil of turpentine is added.

Gum-copal, and amber, are the substances principally employed in oil varnishes; the copal being whitest, is used for varnishing light; the amber for dark colours.

It is best to dissolve them before mixing them with the oil; because, by this means, they are in less danger of being scorched, and at the same time the varnish is more beautiful. They should be melted in an iron pot over the fire; they are in a proper state for receiving the oil when they give no resistance to the iron spatula, and when they run off from it drop by drop.

To make oil varnish, pour four, six, or eight ounces of drying-oil among sixteen ounces of melted copal, or amber, by little and little, constantly stirring the ingredients at the same time with the spatula. When the oil is well mixed with the copal or amber, take it off the fire; and when it is pretty cool, pour in sixteen ounces of the essence of Venice turpentine. After the varnish is made, it should be passed through a linen cloth.

Oil varnishes become thick by keeping; but when they are to be used, it is only necessary to pour in a little Venice-turpentine, and to put them a little on the fire. Less turpentine is necessary in summer than in winter; too much oil hinders the varnish from drying; but when too little is used, it cracks, and does not spread properly.

Black varnishes for coaches and iron-work. This varnish is composed of asphaltum, resin, and amber, melted separately, and afterwards mixed; the oil is then added, and afterwards the turpentine, as directed above. The usual proportions are, twelve ounces of amber, two of resin, two of asphaltum, six of oil, and twelve of turpentine.

A varnish for rendering silk water and air-tight. To render the linseed-oil drying, boil it with two ounces of sugar of lead, and three ounces of litharge, for every pint of oil, till the oil has dissolved them; then put a pound of birdlime, and half a pint of the drying-oil, into a pot of iron or copper, holding about a gallon; and let it boil gently over a slow charcoal fire, till the birdlime ceases to crackle; then pour upon it two pints and a half of drying-oil, and boil it for about an hour longer, stirring it often with an iron or wooden spatula. As the varnish, in boiling, swells much, the pot should be removed from the fire, and replaced when the varnish subsides. While it is boiling, it should be occasionally examined, in order to determine whether it has boiled enough. For this purpose, take some of it upon the blade of a large knife, and after rubbing the blade of another knife upon it, separate the knives; and when, on their separation, the varnish begins to form threads between the two knives, it has boiled enough, and should be removed from the fire. When it is almost cold, add about an equal quantity of spirit of turpentine; mix both well together, and let the mass rest till the next day; then, having warmed it a little, strain and bottle it. If it is too thick, add spirit of turpentine. This varnish should be laid upon the stuff when perfectly dry, in a lukewarm state; a thin coat of it upon one side, and, about twelve hours after, two other coats should be laid on, one on each side; and in 24 hours the silk may be used.

Mr. Blanchard's varnish for air-balloons. Dissolve elastic gum (caoutchouc, or Indian rubber), cut small, in five times its weight of spirit of turpentine, by keeping them some days together; then boil one ounce of this solution in eight ounces of drying linseed-oil for a few minutes, and strain it. Use it warm.

Essential oil varnish. The essential varnishes consist of a solution of resin in oil of turpentine, or other essential oil. This varnish being applied, the turpentine evaporates, leaving the resin behind. They are commonly used for pictures.

Spirit varnishes. When resins are dissolved in alcohol, commonly called spirit of wine, the varnish dries very speedily, but is subject to crack. This fault is corrected by adding a small quantity of oil of turpentine, which renders it brighter, and less brittle when dry.

To dissolve gum-copal in spirit of wine. Dissolve half an ounce of camphor in a pint of alcohol, or spirit of wine; put it into a circulating glass, and add four ounces of copal in small pieces; set it in a sand-heat so regulated, that the bubbles may be counted as they rise from the bottom; and continue the same heat till the solution is completed.

Camphor acts more powerfully upon copal than any other substance. If copal is finely powdered, and a small quantity of dry camphor rubbed with it in the mortar, the whole becomes in a few minutes a tough coherent mass. The process above described will dissolve more copal than the menstruum will retain when cold. The most economical method will therefore be, to set the vessel which contains the solution by for a few days; and when it is perfectly settled, pour off the clear varnish, and leave the residuum for a future operation.

This is a very bright solution of copal; it is an excellent varnish for pictures, and may perhaps be found to be an improvement in fine japan works; as the stoves used in drying those articles may drive off the camphor entirely, and leave the copal pure and colourless upon the work.

A varnish for wainscot, cane-chairs, &c. Dissolve in a quart of spirit of wine, eight ounces of gum-sandarach, two ounces of seed-lac, and four ounces of resin; then add six ounces of Venice turpentine. If the varnish is to produce a red colour, more of the lac and less of sandarach should be used, and a little dragon's-blood should be added. This varnish is very strong.

A varnish for toilet-boxes, cases, fans, &c. Dissolve two ounces of gum-mastich, and eight ounces of gum-sandarach, in a quart of alcohol: then add four ounces of Venice-turpentine.

A varnish for violins, and other musical instruments. Put four ounces of gum-sandarach, two ounces of lac, two ounces of gum-mastich, an ounce of gum-elemi, into a quart of alcohol, and hang them over a slow fire till they are dissolved; then add two ounces of turpentine.

Varnish for employing vermilion for painting equipages. Dissolve in a quart of alcohol six ounces of sandarach, three ounces of gum-lac, and four ounces of resin; afterwards add six ounces of the cheapest kind of turpentine; mix it with a proper quantity of vermilion when it is to be used.

Seed-lac varnish. Take spirit of wine, one quart; put it in a wide-mouthed bottle; add to it eight ounces of seed-lac, that is large-grained, bright, and clear, free from dirt and sticks; let it stand two days, or longer, in a warm place, often shaking it. Strain it through a flannel into another bottle, and it is fit for use.

Shell-lac varnish. Take one quart of spirit of wine, eight ounces of the thinnest and most transparent shell-lac, which, if melted in the flame of a candle, will draw out in the longest and finest hair; mix and shake these together, and let them stand in a warm place for two days, and it is ready for use. This varnish is softer than that which is made from seed-lac, and therefore is not so useful; but may be mixed with it for varnishing wood, &c.

White varnish for clock-faces, &c. Take of spirit of wine (highly rectified) one pint, which divide into four parts; then mix one part with half an ounce of gum-mastich, in a phial; one part of spirit, and half an ounce of gum-sandarach, in another phial; one part of spirit, and half an ounce of the whitest parts of gum-benjamin. Then mix and temper them to your mind. It would not be amiss to add a little bit of white resin, or clear Venice-turpentine, in the mastich-bottle; it will assist in giving a gloss. If your varnish proves too strong and thick, add spirit of wine only; if too hard, some dissolved mastich; if too soft, some sandarach or benjamin. No other rule can be given, unless the quality of the gums and the spirit could be ascertained. When you have brought it to a proper temper, warm the silvered plate before the fire, and with a flat camel's-hair pencil, stroke it all over until no white streaks appear.

Varnish, among medallists, signifies the colours antique medals have acquired in the earth.

The beauty which nature alone is able to give to medals, and art has never yet attained to counterfeit, enhances the value of them; that is, the colours, with which certain soils, in which they have a long time lain, tinge the metals; some of which are blue, almost as beautiful as the turquoise; others with an inimitable vermilion colour; others with a certain shining polished brown, vastly finer than Brasil figures.

The most usual varnish is a beautiful green, which hangs to the finest strokes without effacing them, more accurately than the finest enamel does on metals. No metal but brass is susceptible of this; for the green rust that gathers on silver always spoils it, and it must be got off with vinegar or lemon-juice.

Falsifiers of medals have a false or modern varnish, which they use on their counterfeits, to give them the appearance, or air, of being antique. But this may be discovered by its softness, it being softer than the natural varnish, which is as hard as the metal itself. Some deposit their spurious metals in the earth for a considerable time, by which means they contract a sort of varnish, which may impose upon the less knowing; others use sal ammoniac, muriat of ammonia, and others burnt paper.

VARRONIA, a genus of plants of the class and order pentandria monogynia. The corolla is five-cleft; drupe with a four-celled nut. There are nine species, shrubs of the West Indies.

VASSAL, in old law-books, denotes a tenant that held in fee of his lord, to whom he vowed fidelity and service.

VATERIA, a genus of the polyandria monogynia class of plants, the flower of which consists of five oval and patent petals; and its fruit is a turbinated, coriaceous, and unilocular capsule, containing a single oval seed. There is one species.

VATICA, a genus of the dodecandria monogynia class and order of plants. The calyx is five-cleft; petals five; anthers 15, sessile, four-celled. There is one species, a tree of China.

VAULT, in architecture, an arched roof, so contrived that the stones which form it sustain each other. Vaults are, on many occasions, to be preferred to soffits or ceilings, as they give a greater height and elevation, and are besides more firm and durable.

Salmasius observes, that the antients had only three kinds of vaults. The first was the fornix, made cradle-wise; the second a testudo, *i.e.* tortoise-wise, which the French call cul de four, or oven-wise; and the third concha, or trumpet-wise. But the moderns have subdivided these three sorts into many more, to which they have given different names, according to their figures and uses; some of them are circular, and others elliptical.

Again, the sweeps of some are larger, others less, portions of a sphere. All such as are above hemispheres are called high, or surmounted vaults; and all that are less than hemispheres, are called low, or surbased vaults, or testudines.

In some vaults the height is greater than the diameter; in others it is less; others again are quite flat, and only made with haunses; others like ovens, or in the form of a cul de four, &c. and others growing wider as they lengthen, like a trumpet.

Vaults, *master*, are those that cover the principal parts of buildings, in contradistinction to the upper or subordinate vaults, which only cover some little part, as a passage or gate, &c.

Vault, *double*, is one that is built over another, to make the outer decoration range with the inner; or, to make the beauty and decoration of the inside consistent with that of the outside, leaves a space between the concavity of the one and the convexity of the other; instances of which we have in the dome of St. Peter's at Rome, St. Paul's at London, and in that of the Invalids at Paris.

Vaults with compartments, are such whose sweep, or inner face, is enriched with pannels of sculpture, separated by platbands. These compartments, which are of different figures according to the vaults, and usually gilt on a white ground, are made with stone or brick walls, as in the church of St. Peter at Rome, or with plaister on timber vaults.

Vaults, *theory of.* A semicircular arch or vault, standing on two piedroits, or imposts, and all the stones that compose them, being cut, and placed in such manner as that their joints or beds, being prolonged, do all meet in the centre of the vault; it is evident that all the stones must be in the form of wedges, *i. e.* must be wider and bigger at top; by means of which they sustain each other, and mutually oppose the effort of their weight, which determines them to fall. The stone in the middle of the vaults, which stands perpendicular to the horizon, and is called the key of the vault, is sustained on each side by two contiguous stones, just as by two inclined planes; and, consequently, the effort it makes to fall is not equal to its weight. But still that effort is the greater, as the inclined planes are less inclined; so that if they were infinitely little inclined, *i.e.* if they were perpendicular to the horizon as well as the key, it will tend to fall with its whole weight, and would actually fall but for the mortar. The second stone, which is on the right or left of the key-stone, is sustained by a third, which, by virtue of the figure of the vault, is necessarily more inclined to the second than the second is to the first; and consequently the second, in the effort it makes to fall, employs a less part of its weight than the first. For the same reason, the stones from the key-stone employ still a less and less part of their weight to the last; which, resting on a horizontal plane, employs no part of its weight, or, which is the same thing, makes no effort at all, as being entirely supported by the impost. Now, in vaults, a great point to be aimed at is, that all the voussoirs, or key-stones, make an equal effort towards falling. To effect this, it is visible, that as each (reckoning from the key to the impost) employs still a less and less part of its whole weight; the first, for instance, only employing one-half; the second, one third; the third, one-fourth, &c. there is no other way of making those different parts equal, but by a proportionable augmentation of the whole; *i. e.* the second stone must be heavier than the first, the third than the second, &c. to the last; which should be infinitely heavier.

M. De la Hire demonstrates what that proportion is, in which the weight of the stones of a semicircular arch must be increased to be in equilibrio, or to tend with equal forces to fall, which is the firmest disposition a vault can have. The architects before him had no certain rule to conduct themselves by, but did all at random. Reckoning the degrees of the quadrant of a circle, from the key-stone to the impost, the extremity of each stone will take up so much the greater arch as it is farther from the key.

M. De la Hire's rule is, to augment the weight of each stone above that of the key-stone, as much as the tangent of the arch of the stone exceeds the tangent of the arch of half the key. Now the tangent of the last stone of necessity becomes infinite, and of consequence its weight should be so too; but, as infinity has no place in practice, the rule amounts to this, that the last stones should be loaded as much as possible, that they may the better resist the effort which the vault makes to separate them; which is called the shoot or drift of the vault. Mr. Parent has since determined the curve, or figure, which the extrados, or outside of a vault, whose intrados, or inside, is spherical, must have, that all the stones may be in equilibrio.

Vault, *key of*, is a stone or brick in the middle of the vault, in form of a truncated cone, serving to bind or fasten all the rest.

UBIQUITARIANS, in church-history, a sect of heretics who sprung up in Germany about the year 1590, and maintained that the body of Jesus Christ is ubique, every where, or in every place, at the same time. However, they were not quite agreed among themselves; some holding, that the body of Jesus Christ, even during his mortal life, was every where; and others dating the ubiquity of his body from the time of his ascension only.

VECTOR, in astronomy, a line supposed to be drawn from any planet moving round a centre, or the focus of an ellipsis, to that centre or focus.

VEER, a sea-term variously used. Thus veering out a rope, denotes the letting it go by hand, or letting it run of itself. It is not used for letting out any running rope except the sheet.

Veer is also used in reference to the wind; for, when it changes often, they say it veers about.

VEGETATION. See Plants, *physiology of*

VEIN. See Anatomy.

Vein, among miners, is that space which is bounded with woughs, and contains ore, spar, canck, clay, chirt, croil, brownhen, pitcher-chirt, cur, which the philosophers call the mother of metals, and sometimes soil of all colours. When it bears ore, it is called a quick vein; when no ore, a dead vein.

VELEZIA, a genus of the pentandria digynia class and order of plants. The calyx is filiform, five-toothed; corolla five-petalled, small; capsules one-celled; seeds numerous. There is one species.

VELLA, a genus of the tetradynamia siliculosa class of plants, with a tetrapetalous cruciform flower; the stamina are six filaments, about the length of the cup; and the fruit is a globose, cristated, bilocular pod, containing a few roundish seeds. There are two species.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being a very strong close tissue. The nap or shag, called also the velveting, of this stuff, is formed of part of the threads of the warp, which the workman puts on a long narrow-channeled ruler or needle, which he afterwards cuts, by drawing a sharp steel tool along the channel of the needle to the ends of the warp.

There are velvets of various kinds, as Plain, that is, uniform and smooth, without either figures or stripes.

Figured velvet, that is, adorned and worked with divers figures, though the ground is the same with the figures; that is, the whole surface velveted.

Ramaged or branched velvet, representing long stalks, branches, &c. on a satin ground, which is sometimes of the same colour with the velvet, but more usually of a different one. Sometimes, instead of satin, they make the ground of gold and silver; whence the denominations of velvets with gold ground, &c.

Shorn velvet, is that wherein the threads, that make the velveting, have been ranged in the channeled ruler, but not cut there. Striped velvet, is that wherein there are stripes of different colours running along the warp; whether these stripes are partly velvet and partly satin, or all velveted. Cut velvet, is that whereon the ground is a kind of taffety, or gros de tours, and the figures velvet.

Velvets are likewise distinguished, with regard to their different degrees of strength and goodness, into velvets of four threads, three threads, two threads, and a thread and a half. The first are those where there are eight threads of shag, or velveting, to each tooth of the reed; and the second have only six, and the rest four.

In general, all velvets, both worked and cut, shorn and flowered, are to have their warp and shag of organsin, spun and twisted, or thrown in the mill; and their woof of silk well boiled, &c.

VENEERING, Vaneering, or Fineering, a kind of marquetry, or inlaying, whereby several thin slices or leaves of fine woods, of different kinds, are applied and fastened on a ground of some common wood.

There are two kinds of inlaying; the one which is the most common and more ordinary, goes no farther than the making of compartments of different woods; the other requires much more art, in representing flowers, birds, and similar figures.

The first kind is properly called veneering; the latter is more properly called marquetry.

The wood used in veneering is first sawed out into slices or leaves about a line in thickness; *i. e.* the twelfth part of an inch. In order to saw them, the blocks or planks are placed upright, in a kind of sawing-press.

These slices are afterwards cut into narrow slips, and fashioned divers ways, according to the design proposed; then the joints having been exactly and nicely adjusted, and the pieces brought down to their proper thickness with several planes for the purpose, they are glued down on a ground or block, with good strong English glue.

The pieces being thus jointed and glued, the work, if small, is put in a press; if large, it is laid on a bench covered with a board, and pressed down with poles or pieces of wood, one end of which reaches to the ceiling of the room, and the other bears on the board.

When the glue is thoroughly dry, it is taken out of the press, and finished; first with little planes, then with scrapers, some of which resemble rasps, which take off the dents, &c. left by the planes.

After it has been sufficiently scraped, they polish it with the skin of a dog-fish, wax, and a brush, or polisher of shave-grass; which is the last operation.

VENIRE FACIAS, in law, a writ judicial awarded to the sheriff to cause a jury of the neighbourhood to appear, when a cause is brought to issue, to try the same; and if the jury come not at the day of this writ, then there shall go a habeas corpora, and after a distress, till they appear. 2 Haw. 298.

Venire facias, is also the common process upon any presentment, being in nature of a summons for the party to appear; and this is a proper process to be first awarded on an indictment for any crime under the degree of treason, or felony, or maihem, except in such cases wherein other process is directed by statute. And if by the return to such venire, it appears that the party has lands in the county, whereby he may be distrained, then a distress infinite shall be issued from time to time till he appears; but if the sheriff returns that he has no lands in his bailiwick, then upon his non-appearance, a writ of capias shall issue to take his body. 4 Black. 313.

VENTILAGO, a genus of the class and order of plants pentandria monogynia. The calyx is tubular; corolla, scales protecting the stamen, which are inserted in the calyx. There is one species, a shrub of the East Indies.

VENTILATOR, a machine by which the noxious air of any close place, as an hospital, gaol, ship, chamber, &c. may be changed for fresh air.

The noxious qualities of bad air have been long known; and Dr. Hales and others have taken great pains to point out the mischiefs arising from foul air, and to prevent or remedy them. That philosopher proposed an easy and effectual one, by the use of his ventilators; the account of which was read before the Royal Society in May 1741. In mines, ventilators may guard against the suffocations, and other terrible accidents, arising from damps. The air of gaols has often proved infectious; and we had a fatal proof of this, by the accident that happened some years since at the Old Bailey sessions. After that, ventilators were used in the prisons, which were worked by a small windmill, as that placed on the top of Newgate; and the prison became more healthy.

Dr. Hales farther suggests, that ventilators might be of use in making salt; for which purpose there should be a stream of water to work them; or they might be worked by a windmill, and the brine should be in long narrow canals, covered with boards of canvas, about a foot above the surface of the brine, to confine the stream of air, so as to make it act upon the surface of the brine, and carry off the water in vapours. Thus it might be reduced to a dry salt, with a saving of fuel, in winter and summer, or in rainy weather, or any state of the air whatever. Ventilators, he apprehends, might also serve for drying linen hung in low, long, narrow galleries, especially in damp or rainy weather, and also in drying woollen cloths after they are fulled or dyed; and in this case, the ventilators might be worked by the fulling watermill. Ventilators might also be an useful appendage to malt and hop-kilns; and the same author is farther of opinion, that a ventilation of warm dry air from the adjoining stove, with a cautious hand, might be of service to trees and plants in green-houses; where it is well known that air full of rancid vapours which perspire from the plants, is very unkindly to them, as well as the vapours from human bodies are to men; for fresh air is as necessary to the healthy state of vegetables, as of animals. Ventilators are also of excellent use for drying corn, hops, and malt. Gunpowder may be thoroughly dried, by blowing air up through it by means of ventilators; which is of great advantage to the strength of it. These ventilators, even the smaller ones, will also serve to purify most easily, and effectually, the bad air of a ship's well, before a person is sent down into it, by blowing air through a trunk reaching near the bottom of it. And in a similar manner may stinking water, and ill-tasted milk, &c. be sweetened, viz. by passing a current of air through them, from bottom to top, which will carry the offensive particles along with it.

The method of drawing off air from ships by means of fire-pipes, which some have preferred to ventilators, was published by sir Robert Moray, in the Philos. Trans. for 1665. These are metal pipes, about $2\frac{1}{2}$ inches diameter, one of which reaches from the fire-place to the well of the ship, and thre others branches go to other parts of the ship; the stove-hole and ash-hole being closed up, the fire is supplied with air through these pipes.

In the latter part of the year 1741, Mr. Triewald, military architect to the king of Sweden, informed the secretary to the Royal Society, that he had in the preceding spring invented a machine for the use of ships of war, to draw out the foul air from under their decks, which exhausted 36172 cubic feet of air in an hour, or at the rate of 21732 tuns in 24 hours. In 1742 he sent one of these to France, which was approved of by the Academy of Sciences at Paris, and the navy of France was ordered to be furnished with the like ventilators.

There are various ways of ventilation, or changing the air of rooms. Mr. Tidd contrived to admit fresh air into a room, by taking out the middle upper sash pane of glass, and fixing in its place a frame box, with a round hole in its middle, about six or seven inches diameter; in which hole are fixed, behind each other, a set of sails of very thin broad copper-plates, which spread over and cover the circular hole, so as to make the air which enters the room, and turning round these sails, to spread round in thin sheets sideways; and so not to incommode persons by blowing directly upon them, as it would do, if it was not hindered by the sails.

This method however is very unseemly and disagreeable in good rooms; and therefore, instead of it, the late ingenious Mr. John Whitehurst substituted another; which was, to open a small square or rectangular hole in the party-wall of the room, in the upper part near the ceiling, at a corner or part distant from the fire; and before it he placed a thin piece of metal or pasteboard, &c. attached to the wall in its lower part just below the hole, but declining from it upwards, so as to give the air, that enters by the hole, a direction upwards against the ceiling, along which it sweeps and disperses itself through the room, without blowing in a current against any person. This method is very useful to cure smoky chimneys, by thus admitting conveniently fresh air. A picture placed before the hole prevents the sight of it from disfiguring the room. This, and many other methods of ventilating, he meant to have published, and was occupied upon, when death put an end to his useful labours. These since have been published, viz. in 1794, 4to. by Dr. Willan.

VENTRILOQUISM, an art by which certain persons can so modify their voice, as to make it appear to the audience to proceed from any distance, and in any direction. Some faint traces of this art are to be found in the writings of the antients; and it is the opinion of M. De la Chapelle, who in the year 1772 published an ingenious work on the subject, that the responses of many of the oracles were delivered by persons thus qualified, to serve the purposes of delusion. As the antient ventriloquists, when exercising their art, seemed generally to speak from their own bellies, the name by which they were designed was abundantly significant: but it is with no great propriety that modern performers are called ventriloquists, and their art ventriloquism, since they appear more frequently to speak from the pockets of their neighbours, or from the roof or distant corners of the room, than from their own mouths or their own bellies.

From Brodeau, a learned critic of the sixteenth century, we have the following account of the feats of a capital ventriloquist and cheat, who was valet-de-chambre to Francis the First. The fellow, whose name was Louis Brabant, had fallen desperately in love with a young, handsome, and rich heiress; but was rejected by the parents as an unsuitable match for their daughter, on account of the lowness of his circumstances. The young lady's father dying, he made a visit to the widow, who was totally ignorant of his singular talent. Suddenly, on his first appearance in open day, in her own house, and in the presence of several persons who were with her, she heard herself accosted, in a voice perfectly resembling that of her dead husband, and which seemed to proceed from above, exclaiming, "Give my daughter in marriage to Louis Brabant; he is a man of great fortune, and of an excellent character. I now endure the inexpressible torments of purgatory, for having refused her to him. If you obey this admonition, I shall soon be delivered from this place of torment. You will at the same time provide a worthy husband for your daughter, and procure everlasting repose to the soul of your poor husband."

The widow could not for a moment resist this dread summons, which had not the most distant appearance of proceeding from Louis Brabant; whose countenance exhibited no visible change, and whose lips were close and motionless, during the delivery of it. Accordingly, she consented immediately to receive him for her son-in-law. Louis's finances, however, were in a very low situation; and the formalities attending the marriage-contract rendered it necessary for him to exhibit some show of riches, and not to give the ghost the lie direct. He accordingly went to work upon a fresh subject, one Cornu, an old and rich banker at Lyons; who had accumulated immense wealth by usury and extortion, and was known to be haunted by remorse of conscience on account of the manner in which he had acquired it.

Having contracted an intimate acquaintance with this man, he, one day while they were sitting together in the usurer's little back parlour, artfully turned the conversation on religious subjects, on demons and spectres, the pains of purgatory, and the torments of hell. During an interval of silence between them, a voice was heard, which to the astonished banker seemed to be that of his deceased father, complaining, as in the former case, of his dreadful situation in purgatory, and calling upon him to deliver him instantly thence, by putting into the hands of Louis Brabant, then with him, a large sum for the redemption of christians then in slavery with the Turks; threatening him at the same time with eternal damnation if he did not take this method to expiate likewise his own sins. The reader will naturally suppose that Louis Brabant affected a due degree of astonishment on the occasion; and further promoted the deception, by acknowledging his having devoted himself to the prosecution of the charitable design imputed to him by the ghost. An old usurer is naturally suspicious. Accordingly the wary banker made a second appointment with the ghost's delegate for the next day; and, to render any design of imposing upon him utterly abortive, took him into the open fields, where not a house, or a tree, or even a bush, or a pit, was in sight, capable of screening any supposed confederate. This extraordinary caution excited the ventriloquist to exert all the powers of his art. Wherever the banker conducted him, at every step his ears were saluted on all sides with the complaints and groans not only of his father, but of all his deceased relations, imploring him for the love of God, and in the name of every saint in the calendar, to have mercy on his own soul and theirs, by effectually seconding with his purse the intentions of his worthy companion. Cornu could no longer resist the voice of heaven, and accordingly carried his guest home with him, and paid him down 10,000 crowns: with which the honest ventriloquist returned to Paris, and married his mistress. The catastrophe was fatal. The secret was afterwards blown, and reached the usurer's ears; who was so much affected by the loss of his money, and the mortifying railleries of his neighbours, that he took to his bed and died.

This trick of Louis Brabant is even exceeded by an innocent piece of waggery played off not forty years ago by another French ventriloquist on a whole community. We have the story from M. De la Chapelle, who informs us, that M. St. Gill, the ventriloquist, and his intimate friend, returning home from a place whither his business had carried him, sought for shelter from an approaching thunder-storm in a neighbouring convent. Finding the whole community in mourning, he enquired the cause, and was told that one of their body had died lately, who was the ornament and delight of the whole society. To pass away the time, he walked into the church, attended by some of the religious, who showed him the tomb of their deceased brother, and spoke feelingly of the scanty honours they had bestowed on his memory. Suddenly a voice was heard, apparently proceeding from the roof of the quire, lamenting the situation of the defunct in purgatory, and reproaching the brotherhood with their lukewarmness and want of zeal on his own account. The friars, as soon as their astonishment gave them power to speak, consulted together, and agreed to acquaint the rest of the community with this singular event, so interesting to the whole society. M. St. Gill, who wished to carry on the joke still farther, dissuaded them from taking this step; telling them that they would be treated by their absent brethren as a set of fools and visionaries. He recommended to them, however, the immediately calling of the whole community into the church, where the ghost of their departed brother might probably reiterate his complaints. Accordingly all the friars, novices, lay-brothers, and even the domestics of the convent, were immediately summoned and collected together. In a short time the voice from the roof renewed its lamentation and reproaches, and the whole convent fell on their faces, and vowed a solemn reparation. As a first step, they chanted a De profundis in a full choir: during the intervals of which the ghost occasionally expressed the comfort he received from their pious exercises and ejaculations on his behalf. When all was over, the prior entered into a serious conversation with M. St. Gill; and on the strength of what had just passed, sagaciously inveighed against the absurd incredulity of modern sceptics and pretended philosophers, on the article of ghosts or apparitions. M. St. Gill thought it now high time to disabuse the good fathers. This purpose, however, he found it extremely difficult to effect, till he had prevailed upon them to return with him into the church, and there be witnesses of the manner in which he had conducted this ludicrous deception.

A ventriloquist, who performed feats somewhat similar to these, made his appearance in Edinburgh, and many of the other towns of Great Britain, a few years ago. He imitated successfully the voice of a squeaking child, and made it appear to proceed from whatever place he chose; from the pockets of the company; from a wooden doll, with which he held many spirited conversations; from beneath a hat or a wine-glass, and out of any person's foot or hand. When the voice seemed to come from beneath a glass or hat, it was dull and on a low key, as sounds confined always are; and what evinced his dexterity was, that when the glass was raised from the table during the time of his speaking, the words or syllables uttered afterwards were on a higher key, in consequence, one would have thought, of the air being readmitted to the speaker. This part of the experiment failed, however, when the management of the glass was at a distance committed to any of the company; but as the room was not well illuminated, we are inclined to attribute this failure to the ventriloquist not being able to perceive at what precise instant of time the glass was removed from the table.

The same artist imitated the tones of a scolding old woman, disturbed at unseasonable hours by a person demanding admission into her house. We have heard that, when in Edinburgh, the same practitioner astonished a number of persons in the Fishmarket, by making a fish appear to speak, and give the lie to its vender, who affirmed that it was fresh, and caught in the morning.

The editor of this dictionary heard some years ago, in Portugal, a ventriloquist who was at least equal to any of those above-mentioned. Indeed, he could scarcely have believed the fact from any authority, had he not been himself an ear-witness. The man held conversations with the figure of a child, which he carried under his cloak, with persons apparently out of the room, in the street, and even on the roof of the house. The voices were all varied according to the character of the person with whom he affected to converse, and it was impossible not to believe that they proceeded from the quarter where he pretended they were stationed.

We have never, we confess, found a satisfactory explanation of this phenomenon. The most plausible is that which refers it to a certain delicacy of ear in the performer. Such an ear, it is observed, perceives every difference which change of place produces in the same sound; and if a person possessed of such an ear has sufficient command over his organs of speech, to produce by them a sound in all respects similar to another proceeding from any distant object, to the audience the sound which he utters must appear to proceed from that object. If this is the true theory of ventriloquism, it does not seem to be possible for the most expert ventriloquist to speak in his usual tones of conversation, and at the same time make the voice appear to come from a distance; for these tones must be supposed familiar to his audience, and to be in their minds associated with the ideas of his figure, place, and distance. There can, however, be no doubt, that if, by a peculiar modification of the organs of speech, a sound of any kind can be produced, which in faintness, tone, body, and in short every other sensible quality, perfectly resembles a sound delivered from the roof of an opposite house, the ear will naturally, without examination, refer it to that situation and distance; the sound which the person hears being only a sign, which he has from his infancy been constantly accustomed, by experience, to associate with the idea of a person speaking from a house-top. If, however, this theory is true, how comes it that ventriloquism is not more frequently and successfully practised? The man whom the editor saw in Portugal, was apparently an ignorant and illiterate person, and either could not, or would not, give any account of the principles of his art.

VENUE, in law, the neighbourhood whence juries are to be summoned for trial of causes. In local actions, as of trespass and ejectment, the venue is to be from the neighbourhood of the place, where the lands in question lie; and in all real actions, the venue must be laid in the county where the thing is for which the action is brought. But in transitory actions, for injuries that may have happened any where, as debt, detinue, slander, or the like, the plaintiff may declare in what county he pleases; and then the trial must be in that county in which the declaration is laid. Though if the defendant will make affidavit, that the cause of action, if any, arose not in that, but in another county, the court will direct a change of the venue, and oblige the plaintiff to declare in the proper county; and the court will sometimes move the venue, from the proper jurisdiction (especially of the narrow and limited kind), upon a suggestion duly supported, that a fair and impartial trial cannot be had therein. 3 Black. 294.

With respect to criminal cases, it is ordained by stat. 21 Jac. I. c. 4, that all informations on penal statutes, shall be laid in the counties where the offences were committed.

VENUS, in astronomy, one of the inferior planets, revolving round the sun in an orbit between that of Mercury and the Earth. See Astronomy.

Venus, in zoology, a genus of insects belonging to the order of vermes testacea. This animal is a tethys; the shell is bivalve; the hinge with three teeth near each other, one placed longitudinally and bent inwards. There are a great many species, of which the most remarkable is the mercenaria, or commercial, with a strong, thick, weighty shell, covered with a brown epidermis; pure white within; slightly striated transversely: circumference above 11 inches. These are called in North America clams; they differ from other species only in having a purple tinge within. Wampum, or Indian money, is made of them.

Venus's *fly-trap*. See Dionæa Muscipula.

VEPRECULÆ, diminutive from vepres, "a briar or bramble;" the name of the 31st order in Linnæus's Fragments of a Natural Method. See Botany.

VERATRUM, a genus of plants of the class polygamia, and order monœcia; and in the natural system arranged under the 10th order, coronariæ. There is no calyx; the corolla has six petals; there are six stamina; the hermaphrodite flowers have three pistils and three capsules. There are four species, none of which are natives of Britain. The most important is the album, or hellebore, the root of which is perennial, about an inch thick, externally brown, internally white, and beset with many strong fibres; the stalk is thick, strong, round, upright, hairy, and usually rises four feet in height; the leaves are numerous, very large, oval, entire, ribbed, plaited, without footstalks, of a yellowish green colour, and surround the stem at its base: the flowers are of a greenish colour, and appear from June to August in very long, and branched, terminal spikes.

It appears from various instances, that every part of the plant is extremely acrid and poisonous, as its leaves and even seeds prove deleterious to different animals. Greding employed it in a great number of cases of the maniacal and melancholic kind; the majority of these, as might be expected, derived no permanent benefit; several, however, were relieved, and five completely cured by this medicine. It was the bark of the root, collected in the spring, which he gave in powder, beginning with one grain: this dose was gradually increased according to its effects. With some patients one or two grains excited nausea and vomiting, but generally eight grains were required to produce this effect, though in a few instances a scrupl and even more was given.

Veratrum has likewise been found useful in epilepsy, and other convulsive complaints; but the diseases in which its efficacy seems least equivocal, are those of the skin; as scabies and different prurient eruptions, herpes, morbus pediculosus, lepra, scrophula, &c. and in many of these it has been successfully employed both internally and externally. As a powerful stimulant and irritating medicine, its use has been resorted to only in desperate cases, and then it is first to be tried in very small doses in a diluted state, and to be gradually increased according to the effects.

VERB, in grammar, a word serving to express what we affirm of any subject, or attribute to it.

VERBASCUM, a genus or plants of the class pentandria, and order monogynia; and in the natural system arranged under the 28th order, luridæ. The corolla is rotated, and rather unequal; the capsule is monolocular and bivalved. There are 19 species, five of which are natives of Britain:

1. The thapsus, or great mullein, which has a stem single, simple, erect, covered with leaves, about six feet high; leaves large, broad, white, woolly on both sides, sessile, decurrent; flowers terminal, in a long spike, sessile, yellow. Catarrhal coughs and diarrhœas are the complaints for which it has been internally prescribed. Dr. Hume tried it in both, but it was only in the latter disease that this plant succeeded. He relates four cases in which a decoction of verbascum was given; and from which he concludes, that it "is useful in diminishing or stopping diarrhœas of an old standing, and often in easing the pains of the intestines. These acquire a great degree of irritability; and the ordinary irritating causes, aliment, bile, distension from air, keep up a quicker peristaltic motion. This is obviated by the emollient and perhaps gentle astringent qualities of this plant."

2. The nigrum, or black mullein, having a stem beset with hairs that are beautifully branched; the blossoms yellow with purple tips. It is a beautiful plant, and the flowers are grateful to bees. Swine eat it; sheep are not fond of it; cows, horses, and goats, refuse it. The other British species are the lychnitis, blattana, and virgatum.

VERBENA, a genus of plants of the class of diandria, and order of monogynia; and in the natural system arranged under the 40th order, personatæ. The corolla is funnel-shaped; calyx one of the teeth truncate; seeds two or four, naked or very thinly arilled; stem two or four. There are 23 species, only one of which is a native of Britain; the officinalis, or common vervain, which grows on the road-sides near towns and villages. The leaves have many jagged clefts, the blossoms are pale blue. It manifests a slight degree of astringency, and was formerly much in use as a deobstruent, but is now disregarded. Mr. Millar says, that it is never found above a quarter of a mile from a house; whence the common people in England call it simpler's joy, because, wherever it is found, it is a certain sign of a house being near. Sheep eat it; cows, horses, and goats, refuse it.

VERBESINA, a genus of the syngenesia

polygamia superflua class of plants, with a radiated flower, made up of hermaphrodite tubulose ones on the disc, and a few lingulated ones on the verge; the seeds are angulated, and contained in the cup. There are eleven species.

VERDEGREASE, or VERDEGRIS. See COPPER.

Verdegris is an acetat of copper, useful in the arts as a pigment. The principles on which it is formed are these:

Acetic acid attacks copper very slowly in open vessels, converts it into an oxide, and dissolves it; but in close vessels no action takes place. This acid readily combines with the oxide of copper, and forms with it an acetat. This salt was known to the antients, and various ways of preparing it are described by Pliny. It is usually obtained by exposing plates of copper to the action of vinegar, till they are converted to a bluish-green powder, and then dissolving this powder in acetic acid, and crystallizing it.

Acetat of copper crystallizes in four-sided truncated pyramids. It has a beautiful bluish-green colour. Its specific gravity is 1.779. Its taste is disagreeably metallic, and, like all the compounds into which copper enters, it is poisonous. It is very soluble in water; alcohol likewise dissolves it. When exposed to the air, it effloresces. By distillation it gives out acetic acid. Proust first remarked that acetous acid and acetic acid form the same salt with copper; and hence concluded that there is no difference between the two acids. When sulphureted hydrogen gas is made to pass through a solution of this salt in water, the copper is deoxidized, and precipitates in the state of a blue sulphuret, and there remains behind an acid which possesses the properties of the acetic.

According to Proust, the acetat of copper is composed of

61	acid and water
39	oxide
100.	

When the verdegris of commerce is put into water, 0.56 parts of it are dissolved, and there remain 0.44 parts in the state of a fine green powder, which remains long suspended in the solution. Mr. Proust has ascertained that this powder is a subacetat of copper. It is decomposed by sulphuric acid, by potass, and by distillation. According to the analysis of Proust, it is composed of

37	acid and water
63	oxide
100.	

Thus it appears from the experiments of this philosopher, that the verdegris of commerce is composed of two different acetats of copper; the one soluble in water, the other insoluble. It is much used as a paint; and crystallized acetat of copper is a frequent ingredient in dying compounds. Verdegris is formed in great quantities at Montpelier. A particular account of the processes followed in that place has been published by Mr. Chaptal.

VERDEROR, a judicial officer of the king's forest, chosen by the king's writ in the full county-court of the same shire, within the forest where he dwells; he is sworn to maintain and keep the assizes of the forest, and to view, receive and enrol the attachments and presentments, of all manner of trespasses of vert and venison in the forest.

VERDICT, the answer of a jury, made upon any cause, civil or criminal, committed by the court to their examination, and this is twofold, general or special.

A general verdict is that which is given or brought into the court in like general terms to the general issue; as in an action of disseisin, the defendant pleads no wrong, no disseisin; then the issue is general, whether the fact is wrong or not; which being committed to the jury, they upon consideration of the evidence come in and say, either for the plaintiff, that it is a wrong and disseisin; or for the defendant, that it is no wrong, no disseisin.

A special verdict, is when they say at large, that such a thing and such a thing they find to be done by the defendant or tenant, so declaring the course of the fact, as in their opinion it is proved; and as to the law upon the fact, they pray the judgment of the court; and this special verdict, if it contains any ample declaration of the cause from the beginning to the end, is also called a verdict at large. Co. Lit. 128.

A special verdict is usually found where there is any difficulty or doubt respecting the laws; when the jury state the facts as proved, and pray the advice of the court thereon. A less expensive, and more speedy mode however, is to find a verdict generally for the plaintiff, subject, nevertheless, to the opinion of the judge, or the court above, on a special case drawn up and settled by counsel on both sides.

VERGE signifies the compass of the king's court, which bounds the jurisdiction of the lord steward of the household, and which is thought to have been 12 miles round.

The term verge is also used for a stick or rod, whereby one is admitted tenant to a copyhold estate, by holding it in his hand, and swearing fealty to the lord of the manor.

VERGERS, certain officers of the courts of kings'-bench and common-pleas, whose business it is to carry white wands before the judges.

There are also vergers of cathedrals, who carry a rod tipped with silver before the bishop, dean, &c.

VERJUICE, a liquor obtained from grapes or apples, unfit for wine or cyder; or from sweet ones, whilst yet acid and unripe. Its chief use is in sauces, ragouts, &c. though it is also an ingredient in some medicinal compositions, and is used by the wax-chandlers to purify their wax.

VERMES, the sixth class of animals in the Linnæan system, comprehending five orders. See NATURAL HISTORY, and ZOOLOGY.

VERNIER SCALE, a scale excellently adapted for the graduation of mathematical instruments, thus called from its inventor Peter Vernier, a person of distinction in the Franche Compté. Vernier's method is derived from the following principle: If two equal right lines, or circular arcs, A, B, are so divided, that the number of equal divisions in B is one less than the number of equal divisions of A, then will the excess of one division of B above one division of A, be compounded of the ratios of one of A to A, and of one of B to B.

For, let A contain 11 parts, then one of A to A is as 1 to 11, or $\frac{1}{11}$. Let B contain 10 parts, then one of B to B is as 1 to 10, or $\frac{1}{10}$. Now $\frac{1}{10} - \frac{1}{11} = \frac{11-10}{10 \times 11} = \frac{1}{10 \times 11} = \frac{1}{10} \times \frac{1}{11}$.

Or if B contains n parts, and A contains $n+1$ parts; then $\frac{1}{n}$ is one part of B, and $\frac{1}{n+1}$ is one part of A. And $\frac{1}{n} - \frac{1}{n+1} = \frac{n+1-n}{n \times \overline{n+1}} = \frac{1}{n} \times \frac{1}{n+1}$.

The most commodious divisions, and their aliquot parts, into which the degrees on the circular limb of an instrument may be supposed to be divided, depend on the radius of that instrument.

Let R be the radius of a circle in inches; and a degree to be divided into n parts, each being $\frac{1}{p}$th part of an inch.

Now the circumference of a circle, in parts of its diameter 2 R inches, is $3{,}1415926 \times 2$ R inches.

Then $360^\circ : 3{,}1415926 \times 2\ \text{R} :: 1^\circ : \frac{3{,}1415926}{360} \times 2$ R inches.

Or, $0{,}01745329 \times$ R is the length of one degree in inches.

Or, $0{,}01745329 \times \text{R} \times p$ is the length of 1°, in pth parts of an inch.

But as every degree contains n times such parts, therefore $n = 0{,}01745329 \times \text{R} \times p$.

The most commodious perceptible division is $\frac{1}{8}$ or $\frac{1}{10}$ of an inch.

Example. Suppose an instrument of 30 inches radius, into how many convenient parts may each degree be divided? how many of these parts are to go to the breadth of the vernier, and to what parts of a degree may an observation be made by that instrument?

Now, $0{,}01745 \times \text{R} = 0{,}5236$ inches, the length of each degree: and if p is supposed about $\frac{1}{8}$ of an inch for one division; then $0{,}5236 \times p = 4{,}188$ shows the number of such parts in a degree. But as this number must be an integer, let it be 4, each being 15′: and let the breadth of the vernier contain 31 of those parts, or $7\frac{3}{4}^\circ$, and be divided into 30 parts.

Here $n = \frac{1}{4}$; $m = \frac{1}{30}$; then $\frac{1}{4} \times \frac{1}{30} = \frac{1}{120}$ of a degree, or 30′, which is the least part of a degree that instrument can show.

If $n = \frac{1}{5}$, and $m = \frac{1}{36}$; then $\frac{1}{5} \times \frac{1}{36} = \frac{60}{5 \times 36}$ of a minute, or 20″.

The following table, taken as examples in the instruments commonly made from 3 inches to 8 feet radius, shows the divisions of the limb to nearest tenths of inches, so as to be an aliquot of 60's and what parts of a degree may be estimated by the vernier, it being divided into such equal parts, and containing such degrees as their columns show.

Rad inches.	Parts in a deg.	Parts in vernier.	Breadth of vernier.	Parts observed.
3	1	15	$15\frac{1}{4}$	4′ 0″
6	1	20	$20\frac{1}{4}$	3 0
9	2	20	$10\frac{1}{4}$	1 30
12	2	24	$12\frac{3}{4}$	1 15
15	3	20	$6\frac{3}{4}$	1 0
18	3	30	$10\frac{1}{4}$	0 40
21	4	30	$7\frac{1}{4}$	0 30
24	4	36	$9\frac{3}{4}$	0 25
30	5	30	$7\frac{1}{2}$	0 20
36	6	30	$5\frac{1}{4}$	0 20
42	8	30	$3\frac{7}{8}$	0 15
48	9	40	$4\frac{5}{9}$	0 10
60	10	36	$3\frac{7}{10}$	0 10
72	12	30	$2\frac{7}{12}$	0 10
84	15	40	$2\frac{2}{3}$	0 6
96	15	60	4	0 4

By altering the number of divisions, either in the degrees or in the vernier, or in both, an angle can be observed to a different degree of accuracy. Thus, to a radius of 30 inches, if a degree is divided into 12 parts; each being five minutes, and the breadth of the vernier is 21 such parts, or $1\frac{3}{4}°$, and divided into 20 parts, then $\frac{1}{12} \times \frac{1}{20} = \frac{1°}{240} = 15''$: or taking the breadth of the vernier $2\frac{7}{2}°$, and divided into 30 parts; then $\frac{1}{12} \times \frac{1}{30} = \frac{1°}{360}$, or $10''$: or $\frac{1}{12} \times \frac{1}{50} = \frac{1°}{600} = 60''$, where the breadth of the vernier is $4\frac{1}{4}°$.

VERONICA, a genus of plants of the class diandria, and order monogynia; and in the natural system arranged under the 40th order, personatæ. The corolla is four-cleft, wheel-shaped, with the lowest segment narrower; capsules superior, two-celled. There are 57 species; 15 are natives of Britain, only two of which have been applied to any use: 1. The officinalis, common male speedwell, or fluelin, growing on heaths and barren grounds. An infusion is recommended by Hoffman as a substitute for tea; but it is more astringent and less grateful. The herb was formerly esteemed in medicine for various disorders, but is now almost totally disused. Cows, sheep, goats, and horses, eat it; swine refuse it. 2. The beccabunga, or common brook-lime. This plant was formerly considered as of much use in several diseases, and was applied externally to wounds and ulcers: but if it has any peculiar efficacy, it is to be derived from its antiscorbutic virtue.

VERSE. See POETRY.

VERSED *sine of an arch*, a segment of the diameter of a circle, lying between the foot of a right sine, and the lower extremity of the arch.

VERT. See HERALDRY.

VERTEBRÆ. See ANATOMY.

VERTEX. See ANATOMY.

VERTICAL circle, in astronomy, a great circle of the sphere passing through the zenith and nadir, and cutting the horizon at right angles: it is otherwise called azimuth.

VERTICAL PLANE, in perspective, is a plane perpendicular to the geometrical plane, passing through the eye, and cutting the perspective plane at right angles.

VERTIGO. See MEDICINE.

VERVAIN. See VERBENA.

VESICA, in anatomy, a bladder; a membranous or skinny part, in which any humour is contained.

VESICATORY, an external medicine, serving to raise a blister; whence also it is itself, though improperly, called a blister.

VESPA, *wasp*, a genus of insects of the order hymenoptera. The generic character is, mouth with jaws, without proboscis; upper wings pleated; sting concealed; eyes lunated; body smooth.

The genus vespa is of great extent, 140 species; and is remarkable, like that of apis or bee, for the singular dexterity with which it constructs its habitation, which in many species is of considerable size. The common wasp, or vespa vulgaris, is known to every one. The nest of this species is a highly curious structure, and is prepared beneath the surface of some dry bank, or other convenient situation. Its shape is that of an upright oval, often measuring ten or twelve inches at least in diameter: it consists of several horizontal stages or stories of hexagonal cells, the interstices of each story being connected at intervals by upright pillars; and the exterior surface of the nest consists of a great many layers or pieces, disposed over each other in such a manner as best to secure the interior cavity from the effects of cold and moisture; the whole nest, comprizing both walls and cells, is composed of a substance very much resembling the coarser kinds of whitish-brown paper, and consists of the fibres of various dry vegetable substances, agglutinated by a tenacious fluid discharged from the mouths of the insects during their operations. The female wasps deposit their eggs in the cells, one in each cell appropriated for that purpose; from these are hatched the larvæ or maggots, which bear a near resemblance to those of bees: they are fed by the labouring wasps with a coarse kind of honey, and when arrived at their full size, close up their respective cells with a fine tissue of silken filaments, and, after a certain period, emerge in their complete or perfect form. The male insect, like the male bee, is destitute of a sting. The society or swarm of the common wasp, consists of a vast number of neutral or labouring insects, a much smaller number of males, and still fewer females. They do not, like bees, prepare and lay up a store of honey for winter use; but the few which survive the season of their birth, remain torpid during the colder months. Wasps in general are both carnivorous and frugivorous.

The hornet, vespa crabo of Linnæus, is a species of a far more formidable nature than the common wasp, and is of considerably larger size: its colour is a tawny yellow with ferruginous and black bars and variegations. The nest of this species is generally built in the cavity of some decayed tree, or immediately beneath its roots; and not unfrequently in timber-yards and other similar situations. It is of smaller size than that of the wasp, and of a somewhat globular form, with an opening beneath; the exterior shell consisting of more or few layers of the same strong paper-like substance with that prepared by the wasp: the cells are also of a similar nature, but much fewer in number, and less elegantly composed. The hornet, like the wasp, is extremely voracious, and preys on almost any kind of fresh animal substances which it can obtain, as well as honey, fruit, &c. &c. Its sting is greatly to be dreaded, and is often productive of very serious consequences.

A highly elegant wasp's nest is sometimes seen during the summer season, attached or hanging by its base to some straw or other projecting substance, from the upper part of unfrequented buildings or outhouses. It does not much exceed the size of an egg, but is of a more globular form, and consists of several concentric bells, with considerable intervals between each, the interior alone being entire, and furnished with a small round orifice: the rest reaching only about two-thirds from the base of the nest. In the centre of the complete or entire bell, is situated the congeries of cells, built round a small central pillar attached to the base: the cells are not very numerous, and their orifices look downwards. See Plate Nat. Hist. fig. 417.

VESPERTILIO, *bat*, a genus of mammalia, of the order primates. The generic character is, teeth erect, sharp-pointed, approximated; hands palmated, with a membrane surrounding the body, and giving the animal the power of flight.

The curious formation of these animals cannot be contemplated without admiration: the bones of the extremities being continued into long and thin processes, connected by a most delicately formed membrane or skin, capable, from its thinness, of being contracted at pleasure into innumerable wrinkles, so as to lie in a small space when the animal is at rest, and to be stretched to a very wide extent for occasional flight.

Should a speculative philosopher, not aware of the anatomical impossibility of success, attempt, by means of light machinery, to exercise the power of flight, he could not hit on a more plausible idea than that of copying the structure described. Accordingly, a celebrated author has most justly and judiciously represented a sage theorist busied in imitating, for this purpose, "the folding continuity of the wing of a bat."

The 26 species of this extraordinary genus may be divided into the tailed and the tailless bats.

1. Vespertilio murinus, the common bat, is about two inches and a half, if measured from the nose to the tip of the tail; and the extent of the wings, when fully expanded, is about nine inches. It is of a mouse-colour, tinged with reddish; the wings and ears black: these latter are small and rounded.

2. Vespertilio auritus, long-eared bat. This species, in its general appearance, is nearly similar to the former, though rather smaller; and the fur has less of the reddish tinge; but what immediately distinguishes it as a species, is the very great size of the ears, which are more than an inch long, and of a very considerable width; they are slightly rounded at the tips, and are furnished internally, as in most others of this genus, with a kind of secondary auricle or internal flap, so placed as to serve by way of a valve or guard to the auditory passage. Linnæus, even in the twelfth edition of the Systema Naturæ, seems to entertain a doubt whether this species is really distinct from the former, or merely a sexual difference.

This and the former are the two most common species in this country; and are those which we so often see fluttering about in the evenings of summer and autumn, frequently uttering a sharp stridulous note or scream during their flight, and pursuing the various kinds of insects on which they feed, particularly moths. They are sometimes taken by throwing up the heads of burdock whitened with flour; which the bats either mistaking for some insect, or casually dashing against, are caught by the hooked prickles and brought to the ground.

The bat is capable, like the mouse, of being tamed to a certain degree; and we are assured by Mr. White, in his Natural History of Selborne, that he was much amused in the summer of the year 1766 with the sight of a tame bat. "It would take flies out of a person's hand. If you gave it any thing to eat, it brought its wings round before the mouth, hovering, and hiding its head, in the manner of birds of prey when they feed. The adroitness it shewed in shearing off the wings of the flies, which were always rejected, was worthy of observation, and pleased me much. Insects seemed to be most acceptable, though it did not refuse raw flesh when offered; so that the notion that bats go down chimneys and gnaw men's bacon, seems no improbable story. While I amused myself with this wonderful quadruped, I saw it several times confute the vulgar opinion, that bats, when down on a flat surface, cannot get on the wing again, by rising with great ease from the floor. It ran, I observed, with more dispatch than I was aware of, but in a most ridiculous and grotesque manner."

Bats are commonly supposed to produce two young at a birth which they suckle for a considerable time. When recently born they adhere most tenaciously to the breast of the parent, so as not to be removed without difficulty.

Bats lodge in great numbers in the cavities of old buildings, under the projections of walls, in the hollows of trees, in rocky places, &c. &c. During winter they lie torpid in these recesses, till the warmth of the vernal atmosphere invites them abroad to make their evening excursions. When taken torpid and brought into a warm situation, they awake from their slumber, and again expand their wings. During this state of torpidity, the circulation of the blood is not to be perceived in the smaller vessels; but when thus awakened by warmth, it again becomes visible by the microscope. This was first observed by Leewenhoeck, who could perceive no appearance of circulation in such as were taken in their torpid state; but on bringing them to the fire, the circulation soon became very brisk.

Bats are said to drink on the wing, like swallows, by sipping the surface, as they play over pools and streams. They love to frequent waters, not only for the sake of drinking, but on account of the insects which are found over them in the greatest plenty.

The general appearance of the bat, together with its nocturnal flight, must be confessed to excite the idea of something hideous and dismal; and for this reason the antients consecrated it to Proserpine, and supposed it to be one of the inhabitants of her dreary regions; and it cannot fail to occur to the recollection of every one, that painters, in their representations of fiends and demons, usually exhibit them with the leathern wings of the bat. It is also equally evident, that the fabulous harpies of the antients must have originated from a similar source; the larger bats of India and Africa, by a little poetical exaggeration of their manners, answering extremely well to the general description of those monsters.

3. Vespertilio noctula, the noctule bat, is considerably larger than the former; its extended wings measuring from 14 to 15 inches: the length from the nose to the tip of the tail about four inches and a half. The nose is slightly bilobated; the ears small and rounded; the body is fleshy and plump; the shoulders very thick and muscular; the fur very soft and glossy, and of a bright chesnut-colour. This is an inhabitant of Britain and of France, but seems not to have been particularized as a distinct species, till described by M. Daubenton in Buffon's Natural History. It is said to be common in some parts of Russia, sheltering in caverns. It flies high in the air in search of food, and does not skim near the surface like the smaller bats. It has been occasionally found in great quantities under the eaves of old buildings, and has generally a strong and unpleasant smell.

5. Vespertilio ferrum equinum, horse-shoe bat, with a horse-shoe-shaped membrane at the tip of the nose; ears large, broad at the base, and sharp-pointed, inclining backward; no smaller or internal ear; colour of the upper part of the body deep-cinereous; of the lower, whitish. There is said to be a greater and smaller variety; perhaps the male and female. The greater is above three inches and a half long from the nose to the tip of the tail; the extent of wings above 14. This species is found in France, and, very rarely, in England. It is also said to be found about the Caspian Sea.

5. Vespertilio auripendulus, slouch-eared bat, with large pendulous ears, pointed at the ends; nose obtuse; tail long, included in a membrane, and terminated with a hook; colour above deep-chesnut, lighter on the belly, and cinereous on the sides; length three inches and four lines; extent of wing 15 inches. Native of Guiana.

6. Vespertilio leporinus, Peruvian bat. Linnæus, as Mr. Pennant well observes, carried away by the love of system, placed this species, in the twelfth edition of the Systema Naturæ, under a distinct genus, by the name of noctilio; stationing it at a great distance from the rest of the bats, in the order glires, next to the squirrels. This he did merely on account of its having only two cutting-teeth in each jaw. But succeeding observations have conspired to prove that the number and disposition of the teeth differ greatly in the different species of the bats; so that if a too rigid regard was paid to this particular, several distinct genera might be instituted instead of one; but the general characters of the bats are so striking as to render this perfectly unnecessary.

The Peruvian bat has a head something like a pug-dog; the ears large and straight, sharp at the ends, and pointing forwards; two canine teeth, and two small cutting teeth between, in each jaw; tail enclosed in the membrane which joins to each hind leg, and is also supported by two long cartilaginous ligaments involved in the membrane; colour of the fur iron-grey; body equal in size to a middling rat; extent of wing two feet five inches. Mr. Pennant observes, that Mr. Schreber's figure of this species is erroneously coloured, being represented of a straw-colour. It is a native of Peru. An extraordinary conformation, according to Seba, takes place in the legs of this bat; the tibia and fibula being placed separately from each other, and each invested by its own distinct and hairy skin. These, however, seem to be nothing more than the two cartilaginous ligaments mentioned by Mr. Pennant.

The remaining species (except the last) are distinguished by having no tails.

7. Vespertilio nasutus, great serotine bat, with a very long, straight, and strong nose, sloping down at the end; ears long, erect, dilated towards the bottom, rounded at the end; colour of the upper parts a reddish chesnut; sides of a clear yellow; remainder of a dirty white; length five inches and eight lines; extent of wings two feet.

This species is described in the supplemental volume of the count de Buffon's Natural History. It is a native of Guiana, where it is said to assemble in meadows, and other open places, in vast numbers; flying in company with goatsuckers, and both together in such numbers as to darken the air.

8. Vespertilio spectrum, spectre bat. This is a large species, and is a native of South America, where it is chiefly seen on palm-trees. The extent of wings is about two feet two inches, or more; and from the nose to the rump seven inches and a half. It has a long nose; large teeth; long, broad, and upright ears; and at the end of the nose is an upright, long, conical membrane, bending at the end. Hair on the body cinereous, and pretty long; wings full of ramified fibres; the membrane extends from hind leg to hind leg. There is no tail; but three tendons run from the rump to the edge of the membrane.

Mr. Buffon supposes this to be the vampire; but if the accounts of that animal's extraordinary faculty may be depended upon, we are still uncertain as to the species; Piso and others, who give the relation, omitting the particular description of the animal; and, indeed, it is most probable that the faculty which gave rise to the name is by no means confined to a single species, but may be practised by several of the larger bats in warm climates. See Plate Nat. Hist. fig. 416.

9. Vespertilio vampyrus, vampire bat. Of this tremendous animal there are some varieties in point of size and colour; or perhaps they may really be distinct races or species, though nearly allied. The largest, or the great Ternate bat, is, in general, about a foot long, with an extent of wings about four feet; but sometimes it is found far larger, and it has been said that specimens have been seen of six feet in extent. The general colour of the body is a deep reddish brown; brighter on the upper part of the neck and shoulders, as well as on the under parts of the body. The nose is sharp and black; the teeth large and sharp: there are four cutting-teeth both above and below, and the canine teeth are large and strong; the tongue is pointed, and terminated by sharp prickles; the ears are naked, blackish, and large, and are of a pointed form. The wings are black, or of the colour of those of the common bat. The membrane is divided behind, quite to the rump, there being no tail; the single claw on

the wings is large and strong, and those on the feet extremely so, as well as much curved.

This is the bat to which Linnæus applied the title of vampire, on the supposition of its being the species of which so many extraordinary accounts have been given relative to its power of sucking the blood both of men and cattle. This it is supposed to perform by inserting its aculeated tongue into the vein of a sleeping person, in so peculiar a manner as not to excite pain, fanning at the same time the air with its wings, by which means the sleep is rendered still more profound. This is what appears at first so extraordinary as to justify a degree of scepticism as to the fact: it is, however, so solemnly related, and seemingly so well authenticated, as to enforce belief. Mr. Condamine assures us, that the large bats have, in certain parts of America, destroyed, by this means, all the great cattle introduced there by the missionaries. It is affirmed by Bontius, as well as Nieuhoff, that the bats of Java attack those who lie with their feet uncovered, whenever they can gain access; and Gumilla, who mentions a greater and lesser kind, found on the banks of the Oronoque, declares them to be equally greedy after human blood. Persons thus attacked have, in consequence, been near passing from a sound sleep into eternity. It is, therefore, very unsafe to sleep with open windows, or in the open air, in those regions.

P. Martyr, who wrote soon after the conquest of South America, says, that in the isthmus of Darien, there are bats which suck the blood of men and cattle, when asleep, to such a degree as to awaken, and even kill them.

An instance is also related in colonel Stedman's Travels in Surinam, as having happened to himself, which puts the matter beyond a doubt.

Lastly, though it seems to have escaped the attention of modern naturalists, the self-same faculty has been, time out of mind, attributed to the common European bats, which are said to bite sleeping persons, and to suck the blood with the greatest avidity. This is mentioned by Aldrovandus, who seems to relate it as a generally-received opinion; observing, at the same time, that their attacks are infinitely inferior to the dangerous ones of the large exotic bats in India and America.

It remains to explain the reason of the term vampire, by which the above large species has been distinguished.

A vampire is an imaginary monster, supposed to suck the blood of sleeping persons. It also alludes to one of the most absurd superstitions that ever entered into the human mind. About the year 1732, an idea arose among the vulgar in some parts of Poland and Hungary, that certain bodies when interred, became possessed of the power of absorbing blood from those who were so unfortunate as to pass over or stand near their graves; it was, therefore, supposed necessary to dis-inter such bodies and wound them with a sword, by which means this pernicious power was supposed to be put a stop to, and the blood they had unjustly gained was evacuated. Astonishing as this folly may appear, it is yet more astonishing that a great many treatises were written on the subject, and that some considerable time elapsed before the superstition was completely destroyed.

VESTALS, *vestales*, among the antient Romans, were priestesses of the goddess Vesta, and had the perpetual fire committed to their charge. They were at first only four in number, but afterwards increased to six; and it does not appear that their number ever exceeded six, among whom one was superior to the rest, and called vestalis maxima.

The vestals were chosen from six to ten years of age, and obliged to strict continency for 30 years; the first ten of which were employed in learning the ceremonies of religion, the next ten in the performance of them, and the ten last in teaching them to the younger vestals. The habit of the vestals consisted of an head-dress, called infula, which sat close to their heads, and whence hung certain laces called vittæ, a kind of surplice made of white linen, and over it a purple mantle with a long train to it.

VESTIBULE, in architecture, a kind of entrance into a large building; being an open place before the hall, or at the bottom of the staircase. Vestibules intended for magnificence, are usually between the court and the garden.

VESTRY, a place adjoining to a church, where the vestments of the minister are kept; also a meeting at such place where the minister, churchwarden,, and principal men of most parishes, at this day make a parish vestry. On the Sunday before a vestry is to meet, public notice ought to be given, either in the church, or after divine service is ended, or else at the church-door as the parishioners come out, both of the calling of the said meeting, and also of the time and place of the assembling of it; and it is reasonable then also to declare for what business the said meeting is to be held, that none may be surprized, but that all may have full time before, to consider of what is to be proposed at the said meeting. Wats. c. 39.

VESUVIAN, a mineral found in lava, especially at Vesuvius, and formerly confounded with hyacinth. Its colour is brown or greenish. It is found in masses, but usually crystallized in rectangular eight-sided prisms. The primitive form of its crystals is the cube. The specific gravity is from 3.39 to 3.4. It scratches glass; the fracture is imperfectly conchoidal. It causes double refraction. Before the blowpipe it melts into yellowish glass. It is composed of

26.5	silica
40.2	magnesia
16.2	oxide of iron
16.0	lime
98.9	

VETCH. See VICIA.

VIBRATION, in mechanics, a regular reciprocal motion of a body, as a pendulum, &c. which, being freely suspended, swings or oscillates, first this way, then that.

VIBRIO, a genus of vermes infusoria. The generic character is, worm invisible to the naked eye, very simple, round, elongated. There are 20 species enumerated, and found chiefly in vegetable infusions.

VIBURNUM, a genus of plants of the class pentandria, order trigynia, and in the natural system arranged under the 43d order, dumosæ. The calyx is quinquepartite and above; the corolla divided into five lachinæ; the fruit a monospermous berry. There are 23 species, two of which are natives of Britain.

1. The lantana, common viburnum, wayfaring, or pliant mealy tree, having very pliant shoots covered with a lightish-brown bark; large heart-shaped, veined, serrated leaves, white and hoary underneath, and the branches terminated by umbels of white flowers, succeeded by bunches of red berries, &c.

2. The opulus, or Guelder rose, consisting of two varieties, one with flat flowers, the other globular. The former grows 18 or 20 feet high, branching opposite, of an irregular growth, and covered with a whitish bark: and large lobated or three-lobed leaves on glandulous footstalks. The latter has large globular umbels of white flowers at the ends of the branches in great abundance. This tree when in bloom exhibits a singularly fine appearance; the flowers, though small, are collected numerously into large globular umbels, round like a ball; hence it is sometimes called snowball-tree.

3. The tinus, common laurustinus, or evergreen viburnum. There are a great many varieties. All the different species of viburnum, both deciduous and evergreen kinds, being of the tree kind, are woody and durable in root, stem, and branches. They may all be propagated by layers; and are of such hardy temperature as to grow freely in the open ground all the year, in shrubberies, and other hardy plantations.

VICAR, one who supplies the place of another. The priest of every parish is called rector, unless the prædial tithes are appropriated, and then he is styled vicar; and when rectories are appropriated, vicars are to supply the rector's place. For the maintenance of the vicar, there was then set apart a certain portion of the tithes, commonly about a third part of the whole, which are now what are called the vicarial tithes, the rest being reserved to the use of the rectors, which for the like reason are denominated the rectorial tithes.

VICARAGE. For the most part vicarages were endowed upon appropriations; but sometimes vicarages have been endowed without any appropriation of the parsonage; and there are several churches where the tithes are wholly impropriated, and no vicarage endowed; and there the impropriators are bound to maintain curates to perform divine service, &c. The parsons, patron, and ordinary, may create a vicarage, and endow it; and in time of vacancy of the church, the patron and ordinary may do it; but the ordinary alone cannot create a vicarage, without the patron's assent.

VICE, in smithery, and other arts employed in metals, is a machine, or instrument, serving to hold fast any thing they are at work upon, whether it is to be filed, bent, rivetted, &c. To file square it is absolutely necessary that the vice should be placed perpendicular, with its chaps parallel to the work-bench.

VICE, *hand*, is a small kind of vice serving to hold the lesser works in, that require often turning about.

Of these there are two kinds: the broad-chapped hand-vice, which is that commonly used; and the square-nosed hand-vice, seldom used but for filing small round work. See SMITHERY.

VICE is also a machine used by the glaziers to turn or draw lead into flat rods, with grooves on each side to receive the edges of the glass. See GLAZIER'S VICE.

VICIA, a genus of plants of the class diadelphia, and order decandria; and in the natural system arranged under the 32d order, papilionaceæ. The stigma is bearded transversely on the lower side. There are 25 species, seven of which are natives of Britain. The most important are:

1. The sativa, common vetch, or tare. The stalks are round, weak, branched, about two feet long. Pinnæ five or seven pair, a little hairy, notched at the end; stipulæ dentated; flowers light and dark purple, on short pedicles, generally two together; pods erect; seeds black. It is known to be an excellent fodder for horses.

2. The cracca, tufted vetch. It has a stem branched, three or four feet long. Leaves pinnated; pinnæ generally 10 or 12 pairs, lance-shaped, downy; stipulæ entire; flowers purple, numerous, pendulous, in imbricated spikes. It is also reckoned an excellent fodder for cattle.

3. The faba, or common garden-bean. It is a native of Egypt. It is too well known to require description.

VICINAGE. *Common of vicinage* is, where the inhabitants of two townships, which lie contiguous, have usually intercommoned with one another, the beasts of the one straying mutually into the other's fields without any molestation from either. This, indeed, is only a permissive right, intended to excuse what in strictness is a trespass in both, and to prevent a multiplicity of suits; and, therefore, either township may inclose and bar out the other, though they have intercommoned time out of mind. Neither has any person of one town a right to put his beasts originally into the other's common; but if they escape and stray there of themselves, the law winks at the trespass. 2 Black. 34. See COMMON.

VIEW, in law, is generally where a real action is brought in any of the courts of record at Westminster, and it shall appear to the court to be proper and necessary that the jurors should have a view, they may order special writs of distringas, or habeas corpora, to issue, commanding the sheriff to have six of the first twelve of the jurors therein named, or of some greater number of them, at the place in question, &c. But as the having a view was not a matter of course, though such a practice had prevailed, and had been abused to the purposes of delay, the court thought it their duty to take care that their ordering a view should not obstruct justice, and prevent the cause from being tried; and they resolved not to order one any more, without a full examination into the propriety and necessity of it. For they were all clearly of opinion that the act of parliament meant that a view should not be granted, unless the court were satisfied that it was proper and necessary; and they thought it better that a cause should be tried upon a view had by any six, or by fewer than six, or even without any view, than be delayed for any greater length of time. Burr. 256.

VILLAIN, or VILLEIN, a man of servile or base degree.

Of these bondmen or villeins, there were two sorts in England: one termed a villain in gross, who was immediately bound to the person of his lord, and his heirs; the other, villein regardant to a manor, being bound to his lord as a member belonging and annexed to a manor whereof the lord was owner.

Both villains regardant, and villains in gross, were transferable by deed from one owner to another. They could not leave their lord without his permission; but if they ran away or were purloined from him, might be claimed and recovered by action like beasts, or other chattels. They held indeed small portions of land to sustain themselves and families; but it was at the mere will of the lord, who might dispossess them whenever he pleased. A villain could acquire no property either in lands or goods; but if he purchased either, the lord might enter upon him, and seize them to his own use. 1 Black. 93.

VILLARIA, a genus of plants of the class and order dioecia pentandria. The calyx has five petals; the perianth. is a three-celled berry. It seems to be little known.

VINCA, in botany, a genus of plants of the class pentandria, and order monogynia; and in the natural system arranged under the 30th order, contortæ. The corolla is twisted; there are two erect follicles; the seeds are naked. There are five species, only two of which are natives of Britain: 1. The major, great periwinkle. 2. The minor, small periwinkle.

VINCULUM, in mathematics, a character in form of a line, or stroke, drawn over a factor, divisor, or dividend, when compounded of several letters or quantities, to connect them, and shew they are to be multiplied, or divided, &c. together by the other term. Thus $d \times \overline{a + b - c}$ shews that d is to be multiplied into $a + b - c$.

VINDEMIATRIX, or VINDEMIATOR, a fixed star of the third magnitude in the constellation Virgo, whose latitude is 16° 12′ 34″ north, and longitude 5° 37′ 40″ of Libra, according to Mr. Flamsteed's catalogue.

VINE. See VITIS.

VINEGAR. See ACID, CHEMISTRY, ACETIC, and ACETOUS ACID.

Vinegar was known many ages before the discovery of any other acid, those only excepted which exist ready-formed in vegetables. It is mentioned by Moses; and indeed seems to have been in common use among the Israelites, and other Eastern nations, at a very early period. It is prepared from wine, from beer, ale, and other similar liquids. These are apt, as every one knows, to turn sour, unless they are kept very well corked. Now sour wine or beer is precisely the same with vinegar.

Boerhaave describes the following method of making vinegar, which is said to be still practised in different places:

Take two large oaken vats or hogsheads, and in each of these place a wooden grate or hurdle at the distance of a foot from the bottom. Set the vessel upright, and on the grate place a moderately close layer of green twigs or fresh cuttings of the vine. Then fill up the vessel with the footstalks of grapes, commonly called the rape, to the top of the vessel, which must be left quite open.

Having thus prepared the two vessels, pour into them the wine to be converted into vinegar, so as to fill one of them quite up, and the other but half-full. Leave them thus for 24 hours, and then fill up the half-filled vessel with liquor from that which is quite full. Four-and-twenty hours afterwards repeat the same operation; and thus go on, keeping the vessels alternately full and half-full during every 24 hours till the vinegar is made. On the second or third day there will arise, in the half-filled vessel, a fermentative motion, accompanied with a sensible heat, which will gradually increase from day to day. On the contrary, the fermenting motion is almost imperceptible in the full vessel; and as the two vessels are alternately full and half-full, the fermentation is by that means, in some measure, interrupted, and is only renewed every other day in each vessel.

When this motion appears to have entirely ceased, even in the half-filled vessel, it is a sign that the fermentation is finished; and therefore the vinegar is then to be put into casks close-stopped, and kept in a cool place.

All that is necessary to convert wine or beer into vinegar, is the contact of the external air, a temperature of 80°, and the presence of some substance to act as a ferment.

Vinegar is a liquid of a reddish or yellowish colour, a pleasant sour taste, and an agreeable odour. Its specific gravity varies from 1.0135 to 1.0251, and it differs also in its other properties according to the liquid from which it has been procured. It is very subject to decomposition; but Scheele discovered that if it is made to boil for a few moments, it may be kept afterwards for a long time without alteration. Besides acetic acid and water, vinegar contains several other ingredients, such as mucilage, tartar, a colouring matter, and often also two or more vegetable acids. When distilled at a temperature not exceeding that of boiling water, till about two thirds of it have passed over, all these impurities are left behind, and the product is pure acid diluted with water.

The acid thus obtained is a liquid as transparent and colourless as water, of a strong acid taste, and an agreeable colour, somewhat different from that of vinegar. In this state it is usually called acetous acid, or distilled vinegar. See ACETOUS ACID.

It may be preserved without alteration in close vessels. When exposed to a moderate heat, it evaporates completely, and without undergoing any change in its properties. When exposed to the action of cold, part of it congeals. The frozen portion, which consists almost entirely of water, may be easily separated; and by this method the acid may be obtained in a high degree of concentration. The more concentrated the acid is, the greater is the cold necessary to produce congelation. Mr. Lowitz has ascertained that the acid itself, how much soever it may be concentrated, crystallizes or congeals at the temperature of —22°.

When acetat of copper, reduced to powder, is put into a retort and distilled, there comes over a liquid at first nearly colourless, and almost insipid, and afterwards a highly concentrated acid. The distillation is to be continued till the bottom of the retort is red-hot. What remains in it then is only a powder of the colour of copper. The acid product, which should be received in a vessel by itself, is tinged green by a little copper which passes along with it; but when distilled over again in a gentle heat, it is obtained perfectly colourless and transparent. The acid thus obtained is exceedingly pungent and concentrated. It was formerly distinguished by the names of radical vinegar, and vinegar of Venice.

This acid is transparent and colourless like water. It has a peculiar aromatic smell when in the state of acetous acid; but concentrated acetic acid, when procured in the usual way, has an empyreumatic odour, mixed with the natural smell of vinegar, owing to a small portion of oil formed during the process.

A much easier method of obtaining acetic acid than that commonly used has been lately pointed out by Mr. Badoilier, apothecary at Chartres. All that is necessary is to distil a mixture of equal parts of acetat of lead and sulphat of copper in a glass retort. The acid comes perfectly pure on the application of a moderate heat.

The specific gravity of distilled vinegar varies from 1.007 to 1.0095; but radical vinegar is much more concentrated. In that state it is extremely pungent and acrid; and when it is applied to the skin, it reddens and corrodes it in a very short time. It is exceedingly volatile; and when heated in the open air, takes fire so readily, that one would be tempted to suspect the presence of ether in it. It unites with water in any proportion; and when concentrated, the mixture evolves a good deal of heat. See ACID, CHEMISTRY, &c.

VINEYARD, a plantation of vines. See VITIS.

The best situation of a vineyard is on the declivity of an hill, lying to the south. For the planting of a vineyard, observe the following method: In the month of July, while the outermost coat of the earth is very dry and combustible, plough up the sward; denshire, or burn-beat it, according to art, and in January following, spread the ashes. The ground being thus prepared, cut your trenches across the hill from east to west, because the vines being thus in ranks, the rising and setting of the sun will by that means pass through the intervals, which it would not do if they were set in any other position, neither would the sun dart its rays upon the plants during the whole course of the day.

Afterwards strain a line, and dig a trench about a foot deep; place your sets in it, about three feet distance one from another; trim off the superfluous roots, leaving no more than three or four eyes or buds upon that which is above ground; and plant them near half a foot deep, sloping, after the manner the quick is commonly set, so that they may point up the hill. That done, take long dung or straw, and lay it on the trenches in a convenient thickness to cover the earth, and preserve the roots from the dry piercing winds, which would otherwise much annoy them, and from the excessive scorching heats in summer; keep them well hoed, and free from weeds, and water them as occasion serves; the best time to plant is in January.

The first pruning of the new-set vine ought not to be till January, and then you should cut off all the shoots as near as you can, sparing but one of the most thriving, on which you are to leave only two or three buds, and so let all rest till May, the second year after planting. Take care then from time to time to destroy the weeds, and clear the roots of all suckers, which do but rob and draw out the virtue of your sets. The same method is to be followed the third year; then dig your whole vineyard, and lay it very level, taking care in this operation not to cut or wound any of the main roots with your spade. As for the younger roots, it is not so material, as they will grow the thicker; and this year you may enjoy some of the fruits of your vineyard, which, if answerable to your expectation, will put you upon providing props for your vines of about four feet long, which must be placed on the north side of the plant. In May, rub off such buds as you suspect will produce superfluous branches. When the grapes are about the size of birding-shot, break off the branches with your hand at the second joint above the fruit, and tie the rest to the prop: here it is most advisable to break, and not cut, your vine; because wounds made with a sharp instrument are not apt to heal, but cause the plants to bleed. See PRUNING.

The fourth year you will be likely to have three or four shoots to every plant; and, therefore, in December, cut off all the branches, except one of the strongest and most thriving, which leave for a standard about four feet high, paring away the rest very close to the body of the mother-plant, which tie to your prop till it is large enough to make a standard of itself. Neither must you suffer any shoot to break out, but such as sprout at the top, four feet from the ground; all which sprouts the French usually prune off every year, and absolutely trust to the new sprouts that are only bearing shoots.

In August, when the fruit begins to ripen, break off such shoots as you find too thick; and if you perceive any plant bleed, rub some ashes on it; or, if that will not do, sear it with a hot iron. When, upon stirring your vineyard, it appears to be poor, prune the vines as before directed; and spread good dung, mixed with lime, over the whole ground, letting it lie all the winter to wash into the earth, mixing about ten bushels of lime with a load of dung; and if some ashes and soot are likewise thrown on, it will do well. Turn in this manure about February, with a slight digging, but not too deep, which should be done in a dry season, and not in wet weather, lest it should make the ground bind too much, and occasion the growth of rank weeds.

VIOL, a stringed instrument resembling in shape and tone the violin, of which it was the origin; that impressive and commanding instrument being little more than an improvement of the old viol. This instrument formerly consisted of five or six strings, the tones of which were regulated by their being brought by the fingers into contact with the frets with which the neck was furnished. The viol was for a long while in such high esteem as to dispute the pre-eminence with the harp, especially in the early times of music in France; and, indeed, being reduced to four strings, and stript of the frets with which viols of all kinds seem to have been furnished till the sixteenth century, it still holds the first place among treble instruments, under the denomination of violin.

VIOLA, a tenor violin. This instrument is similar in its tone and formation to the violin; but its dimensions are somewhat greater, and its compass a fifth lower in the great scale of sounds. Its lowest note is C on the fourth space in the bass. The part it takes in concert is between that of the bass and the second violin.

VIOLA, a genus of plants of the class syngenesia, order monogynia; in the natural system arranged under the 29th order, campanaceæ. The calyx is pentaphyllous; the corolla five-petalled, irregular, with a nectarium behind, horn-shaped; the capsule is above the germen, three-valved, monolocular. There are 43 species, six of which are natives of Britain. The most important of these are:

1. The palustris, marsh violet. The leaves are smooth, reniform, two or three on each footstalk; flowers pale blue, small, inodorous. An infusion of the flowers is an excellent test of the presence of acids and alkalies.

2. The odorata, purple sweet violet, has leaves heart-shaped, notched; flowers deep purple, single; creeping scions. The flowers of this plant taken in the quantity of a dram or two, are said to be gently purgative or laxative, and, according to Bergius and some others, they possess an anodyne and pectoral quality. There is a variety with white flowers.

3. Tricolor, pansies, heart's-ease, or three faces under a hood. The stems are diffuse, procumbent, triangular; the leaves oblong, cut at the edges; stipulæ dentated; the flowers purple, yellow, and light blue, inodorous. This elegant little plant merits culture in every garden, for the beauty and great variety of its three-coloured flowers; and it will succeed any where in the open borders, or other compartments, disposed in patches towards the front, either by sowing the seed at once to remain, or by putting in young plants. They will begin flowering early in summer, and will continue shooting and flowering in succession till winter; and even during part of that season in mild weather. The common violet is propagated by parting the roots, sometimes by seed.

VIOLIN, or FIDDLE, a well-known stringed instrument of brilliant tone and active execution. When, or by what nation, this important and interesting instrument was first invented, is not at present known; nor can the form and character of the violin used in England in the time of Chaucer, who mentions it, be exactly ascertained. There is, however, much reason for supposing that from its first introduction it underwent continual alterations and improvements, since even towards the end of the sixteenth century its shape appears to have been vague and undetermined. It has, however, long attained its present excellence, and formed the leading instrument in concert. The four strings of which it consists are tuned in fifths from each other. The pitch of the lowest string is G, under the second ledger line in the treble stave; consequently that of the next is D, under the first line of the stave; the pitch of the next above that, A on the second space; and that of the upper string, E on the fourth space. During the Protectorship the violin was in little esteem, and gave way to the rising prevalence of the viol; but at the Restoration, viols began to be out of fashion, and violins resumed their former consequence. The antiquity of this instrument has long been a subject of dispute ith the learned. It is generally supposed, nd with much reason, that no instrument layed with the bow was known to the ancients.

VIOLONCELLO, a bass viol, containing four strings, the lowest of which is tuned to double C. The strings are in fifths, consequently the pitch of that next the gravest is G gamut; that of the next, D on the third line in the bass; and that of the upper string, A on the fifth line.

The violoncello was called the violono till the introduction of the double-bass, which assumed that name.

VIPER. See COLUBER.

VIRCETA, a genus of plants of the pentandria monogynia class and order. The calyx is five-notched; corolla funnel-form; stigma two-parted; capsule one-celled, many-seeded. There are two species, annuals of Guiana.

VIRGO, in astronomy, one of the signs or constellations of the zodiac, and the sixth according to order.

VISCERA. See ANATOMY.

VISCUM, a genus of plants of the class diœcia, order tetrandria, and in the natural system arranged under the 48th order, aggregatæ. The male calyx is quadripartite; the antheræ adhere to the calyx; the female calyx consists of four leaves; there is no style; the stigma is obtuse; there is no corolla; the fruit is a berry with one seed. There are 12 species, only one of which is a native of Britain, viz. the album, or common misseltoe. It is a shrub growing on the bark of several trees. The leaves are conjugate and elliptical; the stem forked; the flowers whitish in the alæ of the leaves. This plant was reckoned sacred among the druids.

VISION. See OPTICS.

VISITATION, in law, an act of jurisdiction whereby a superior, or proper officer, visits some corporation, college, church, or other public or private house, to see that the laws and regulations thereof are duly observed.

Among us, visitation is that office performed by the bishop in every diocese once in three years, or by the archdeacon every year, by visiting the churches and their rectors throughout the whole diocese, &c. The bishop's commissary also holds a court of visitation, to which he may cite all churchwardens and sidesmen; and to whom he exhibits his articles, and makes inquiry by them.

VISMEA, a genus of the dodecandria trigynia class and order of plants. The calyx is five-leaved, inferior; the corolla five-petalled; stigmas five; nect. two or three-celled. There is one species, a native of the Canaries.

VITEX, the *chaste-tree*, a genus of the didynamia angiospermia class of plants, with a monopetalous ringent, and bilabiated flower, each lip of which is trifid; the fruit is a quadrilocular, globose berry, containing four seeds. There are 14 species.

VITIS, a genus of the class pentandria, and order monogynia; and in the natural system arranged under the 46th order, pectoraceæ. The petals cohere at the top, and are withered; the fruit is a berry with five seeds. There are 12 species; the most important of which is the vinifera, or common vine, which has naked, lobed, sinuated leaves. There are a great many varieties; but a recital of their names would be tiresome without being useful. All the sorts are propagated either from layers or cuttings; the former of which methods is greatly practised in England, but the latter is much preferable.

In choosing the cuttings, you should always take such shoots of the last year's growth as are strong and well ripened; these should be cut from the old vine, just below the place where they were produced, taking a knot or piece of the two years' wood to each, which should be pruned smooth; then you should cut off the upper part of the shoots, so as to leave the cutting about 16 inches long. When the piece or knot of old wood is cut at both ends, near the young shoot, the cutting will resemble a little mallet; whence Columella gives the title of malleolus to the vine-cuttings. In making the cuttings after this manner, there can be but one taken from each shoot; but most persons cut them into lengths of about a foot, and plant them all.

When the cuttings are thus prepared, if they are not then planted, they should be placed with their lower part in the ground in a dry soil, laying some litter upon their upper parts to prevent them from drying. In this situation they may remain till the beginning of April (which is the best time for planting them); when you should take them out, and wash them from the filth they have contracted; and if you find them very dry, you should let them stand with their lower parts in the water six or eight hours, which will distend their vessels, and dispose them for taking root. If the ground is strong and inclined to wet, you should open a trench where the cuttings are to be planted, which should be filled with lime-rubbish, the better to drain off the moisture; then raise the borders with fresh light earth about two feet thick, so that it may be at least a foot above the level of the ground; then you should open the holes at about six feet distance from each other, putting one good strong cutting into each hole, which should be laid a little sloping, that their tops may incline to the wall; but it must be put in so deep, that the uppermost eye may be level with the surface of the ground; for when any part of the cutting is left above ground, most of the buds attempt to shoot, so that the strength of the cuttings is divided to nourish so many shoots, which must consequently be weaker than if only one of them grew; whereas, by burying the whole cutting in the ground, the sap is all employed on one single shoot, which consequently will be much stronger; besides, the sun and air are apt to dry that part of the cutting which remains above ground, and so often prevent the buds from shooting.

Having placed the cutting in the ground, fill up the hole gently, pressing down the earth with your foot close about it, and raise a little hill just upon the top of the cutting, to cover the upper eye quite over, which will prevent it from drying. Nothing more is necessary than to keep the ground clear from weeds until the cuttings begin to shoot; at which time you should look over them carefully, to rub off any small shoots, if such are produced, fastening the first main shoot to the wall, which should be constantly trained up, as it is extended in length, to prevent its breaking or hanging down. You must continue to look over these once in about three weeks during the summer season, constantly rubbing off all lateral shoots which are produced; and be sure to keep the ground clear from weeds, which, if suffered to grow, will exhaust the goodness of the soil, and starve the cuttings. The Michaelmas following, if your cuttings have produced strong shoots, you should prune them down to two eyes. In the spring, after the cold weather is past, you must gently dig up the borders to loosen the earth; but you must be very careful, in doing this, not to injure the roots of your vines; you should also raise the earth up to the stems of the plants, so as to cover the old wood but not so deep as to cover either of the eyes of the last year's wood. After this they will require no farther care until they begin to shoot; when you should rub off all weak dangling shoots, leaving no more than the two produced from the two eyes of the last year's wood, which should be fastened to the wall. From this time till the vines have done shooting, you should look them over once in three weeks or a month, to rub off all lateral shoots as they are produced, and to fasten the main shoots to the wall as they are extended in length; about the middle or latter end of July, it will be proper to nip off the tops of these two shoots, which will strengthen the lower eyes. During the summer season you must constantly keep the ground clear from weeds, nor should you permit any sort of plants to grow near the vines, which would not only rob them of nourishment, but shade the lower parts of the shoots, and prevent their ripening, which will not only cause their wood to be spongy and luxuriant, but render it less fruitful.

As soon as the leaves begin to drop in autumn, you should prune these young vines again, leaving three buds to each of the shoots, provided they are strong, otherwise it is better to shorten them down to two eyes, if they are good; for it is a very wrong practice to leave much wood upon young vines, or to leave their shoots too long, which greatly weakens the roots; then you should fasten them to the wall, spreading them out horizontal each way, that there may be room to train the new shoots the following summer, and in the spring the borders must be digged as before.

The uses of the fruit of the vine for making wine, &c. are well known. The vine was introduced by the Romans into Britain, and appears formerly to have been very common. From the name of vineyard yet adhering to the ruinous sites of our castles and monasteries, there seem to have been few in the country but what had a vineyard belonging to them. The county of Gloucester is particularly commended by Malmsbury, in the twelfth century, as excelling all the rest of the kingdom in the number and goodness of its vineyards. In the earlier periods of our history, the isle of Ely was expressly denominated the Isle of Vines by the Normans. Vineyards are frequently noticed in the descriptive accounts of doomsday; and those of England are even mentioned by Bede, as early as the commencement of the eighth century.

Doomsday exhibits to us a particular proof that wine was made in England during the period preceding the Conquest; and after the Conquest, the bishop of Ely appears to have received at least three or four tuns of wine annually as tithes, from the produce of the vineyards in his diocese, and to have made frequent reservations in his leases of a certain quantity of wine for rent. A plot of land in London, which now forms East Smithfield and some adjoining streets, was withheld from the religious house within Aldgate by four successive constables of the Tower, in the reigns of Rufus, Henry, and Stephen, and made by them into a vineyard, which yielded great emolument. In the old accounts of rectorial and vicarial revenues, and in the old registers of ecclesiastical suits concerning them, the tithe of wine is an article that frequently occurs in Kent, Surry, and other counties. And the wines of Gloucestershire, within a century after the Conquest, were little inferior to the French in sweetness. The beautiful region of Gaul, which had not a single vine in the days of Cæsar, had numbers so early as the time of Strabo. The south of it was particularly stocked with them; and they had even extended themselves into the interior parts of the country; but the grapes of the latter did not ripen kindly. France was famous for its vineyards in the reign of Vespasian, and even exported its wines to Italy. The whole province of Narbonne was then covered with vines; and the wine-merchants of the country were remarkable for knavish dexterity, tinging it with smoke, colouring it (as was suspected) with herbs and noxious dyes, and even adulterating the taste and appearance with aloes. And as our first vines would be transplanted from Gaul, so were in all probability those of the Allobroges in Franche-compté. These were peculiarly fitted for cold countries. They ripened even in the frosts of the advancing winter; and they were of the same colour, and seem to have been of the same species, as the black muscadines of the present day, which have lately been tried in this island, and found to be fittest for the climate. These were pretty certainly brought into Britain a little after the vines had been carried over all the kingdoms of Gaul, and about the middle of the third century, when the numerous plantations had gradually spread over the face of the latter, and must naturally have contributed to their progress into the former.

The Romans, even nearly to the days of Lucullus, were very seldom able to regale themselves with wine. Very little was then raised in the compass of Italy; and the foreign wines were so dear, that they were rarely produced at an entertainment; and when they were, each guest was indulged only with a single draught. But in the seventh century of Rome, as their conquests augmented the degree of their wealth, and enlarged the sphere of their luxury, wines became the object of particular attention. Many vaults were constructed, and good stocks of liquor were deposited in them; and this naturally gave encouragement to the wines of the country. The Falernian rose immediately into great repute; and a variety of others, that of Florence among the rest, succeeded it about the close of the century; and the more westerly parts of the European continent were at once subjected to the arms, and enriched with the vines, of Italy. See VINEYARD, and WINE.

VITMANNIA, a genus of plants of the class and order octandria monogynia. The calyx is four-cleft; corolla four petalled; nect. a scale of the base of each filament; nut semilunar, one-seeded. There is one species, a tree of the East Indies.

VITREOUS *humour of the eye*. See OPTICS.

VITRIOL, *martial*, or *sulphat of iron*. This salt was known to the antients, and is mentioned by Pliny under the names of misy, sory, and calchantum. In commerce it is usually denominated green vitriol or copperas. It is not prepared by dissolving iron in sulphuric acid, but by moistening the pyrites which are found native in abundance, and exposing them to the open air. They are slowly covered with a crust of sulphat of iron, which is dissolved in water, and afterwards obtained in crystals by evaporation. Sometimes the salt is found ready-formed, either in a state of solution in water, or mixed with decayed pyrites. In some cases it is found necessary to roast the pyrites before they can be made to undergo spontaneous decomposition. This is most probably owing to the compact state of the pyrites in these cases, and the absence of all uncombined iron. Pyrites is in fact a supersulphuret of iron. The roasting reduces it to the state of a sulphuret, which decomposes very readily.

Sulphat of iron has a fine green colour. Its crystals are transparent rhomboidal prisms, the faces of which are rhombs with angles of 79° 50′ and 100° 10′, inclined to each other at angles of 98° 37′ and 81° 23′. It has a very strong styptic taste, and always reddens vegetable blues. Its specific gravity is 1.8399. It is soluble in about two parts of cold water, and in $\frac{3}{4}$ths of its weight of boiling water. It is insoluble in alcohol.

VITRIOL, *blue*, or *sulphat of copper*. Sulphuric acid does not attack copper while cold, but at a boiling heat part of the acid is decomposed, the copper is oxidized, and combines with the remainder of the acid. But recourse is seldom had to this process, as the sulphat of copper is found native abundantly, dissolved in mineral waters connected with copper-mines. From these waters it is often obtained by evaporation; or it is formed by burning native sulphuret of copper, or by moistening that substance, and exposing it to the air. By either of these methods the sulphur is acidified, and the sulphat of copper formed. This salt appears to have been known to the antients. In commerce it is distinguished by the name of blue vitriol, and sometimes by that of blue copperas. It is, in fact, an oxysulphat. There are two varieties of this salt known, namely, supersulphat, and subsulphat.

VITRIOL, *white*, or *sulphat of zinc*. This salt, according to the best accounts, was discovered at Rammelsberg in Germany about the middle of the 16th century. Many ascribe the invention to Julius duke of Brunswick. Henkel and Newmann were the first chemists who proved that it contained zinc; and Brandt first ascertained its composition completely. It is generally formed for commercial purposes from sulphureted zinc; or blende, as it is called by mineralogists. This ore is roasted, which converts the sulphur into an acid; it is then dissolved in water, and concentrated so much, that on cooling it crystallizes very rapidly, and forms a mass not unlike loaf-sugar. This salt is usually called white vitriol. It is almost always contaminated with iron, and often with copper and lead. Hence the yellow spots which are visible on it, and hence also the reason that its solution in water lets fall a dirty-brown sediment; a circumstance very much complained of by surgeons when they use that solution in medicine. It may be easily purified by dissolving it in water, and putting into the solution a quantity of zinc-filings; taking care to agitate it occasionally. The zinc precipitates foreign metals, and takes their place. The solution is then to be filtered, and the sulphat of zinc may be obtained from it in crystals by proper evaporation.

We have inserted these three articles under the vulgar names in compliance with common prejudice. They are, however, noticed under their proper heads, and we trust the advancement of chemical knowledge will shortly banish these barbarous terms.

VITUS's DANCE. See MEDICINE.

VIVERRA, a genus of quadrupeds of the order of feræ. The generic character is, cutting-teeth six, sharpish; canine teeth longer; tongue in some smooth, in others aculeated backwards; body of a lengthened form. This genus comprehends all the animals of the weesel kind, which seem to be somewhat unnecessarily separated by Linnæus into two distinct genera, under the titles viverra and mustela; in which latter genus the otters are also included. In this particular Mr. Pennant seems to have acted more judiciously than Linnæus. We shall therefore follow his example, and unite the two genera, preserving the otters distinct under the term MUSTELA, which see.

The general character of the weesel tribe (of which there are about 31 species) is, a certain slenderness and length of body; with a sharpened visage, short legs, and, in most species, a longish tail (though in some few it is short).

1. Viverra ichneumon. The ichneumon is a species of which there seem to be two distinct varieties; one of which is a native of India, and the other of Africa. Both agree in their general appearance, but the Egyptian variety is considerably larger than the Indian, measuring more than forty inches from the nose to the end of the tail; whereas the Indian ichneumon scarcely exceeds two-thirds of this length. Exclusive of size alone, the Egyptian ichneumon is distinguished by having the tail slightly tufted at the end, which the other has not; and from this circumstance it is placed, in the Gmelinian edition of the Systema Naturæ, as a distinct species. The ichneumon is of a pale reddish-grey colour, each hair being mottled with brown or dusky, so that the whole appears speckled in the manner of the hair on some of the larger baboons. The eyes are of a bright red or flame-colour; the ears rounded, and almost naked; the nose long and slender; the body rather thicker than in most of this genus; and the tail is very thick at the base, and thence gradually tapers almost to a point; the legs are short; the hair on the whole animal is hard and coarse, and it varies somewhat as to the depth and cast of its colours in different individuals. In India, but still more in Egypt, the ichneumon has always been considered as one of the most useful and estimable of animals; since it is an inveterate enemy to serpents, rats, and other noxious creatures

hich infest those regions. In India it attacks, with the greatest eagerness and courage, that most dreadful reptile the cobra de capello, or hooded snake, and easily destroys it. It also diligently seeks for the eggs of crocodiles; for which reason, as well as for its general usefulness in destroying all manner of troublesome reptiles, it was held in such a high degree of veneration by the ancient Egyptians as to be regarded in the light of a minor deity, one of those benevolent beings proceeding from the parent of the universe. For the purposes above specified it is still domesticated by the Indians and Egyptians, in the same manner as the cat in Europe; and it has also the merit of being easily tamed, and of performing all the services of the cat with a still greater degree of vigour and alacrity. When in pursuit of prey, it sometimes springs suddenly upon it with the greatest agility; and at other times will glide along the ground like a serpent, without raising its body, till it arrives at a proper distance for its intended attack. Like many other animals of this tribe, it is a most dangerous enemy to several creatures larger than itself; over which it gains a ready victory, by fastening itself upon them, and sucking their blood. In a wild state, it is said principally to frequent the banks of rivers; and in times of flood to approach the higher grounds and inhabited places, in quest of prey. It is reported to swim and dive occasionally, in the manner of the otter, and to continue beneath the water for a great length of time.

The ichneumon is found not only in various parts of India, but in the Indian islands, as Ceylon and others. It also occurs in many parts of Africa besides Egypt, as in Barbary, and at the Cape of Good Hope, &c. As it is a native of warm countries, it is of course greatly injured by a removal to the colder regions of Europe, and generally falls a victim to the alteration of climate. See Plate Nat. Hist. fig. 418.

2. Viverra surikatta. The surikate is distinguished by a long sharp-pointed nose, depressed head, and inflated cheeks; the upper jaw is much longer than the lower, and on its upper part is black; the eyes are also surrounded by black; the ears are small and rounded; the tongue is oblong, blunt, and aculeated backwards; the length of the animal, exclusive of the tail, is about a foot, and of the tail about eight inches; the legs are short; the claws on the fore feet much exceed in length those of the hind feet. The general colour of the surikate is a deep grey; the tail is subferruginous, tipped with black. It is an inhabitant of the Cape of Good Hope, where it is called meer-rat. It feeds on flesh, and preys on mice, and other small animals. It commonly sits erect, in the manner of a squirrel; and when pleased makes a rattling noise with its tail, for which reason the Dutch inhabitants of the Cape call it klapper-maus. It is also found in the island of Java, where it is named surikatje by the Dutch, on account of a peculiarly acid scent, which it is said to emit. It is an animal of a capricious disposition when in a state of captivity. In having only four toes, it differs from most of this tribe.

3. Viverra nasua. The size of this animal is at least equal to that of a cat. Its general colour is a cinereous brown, or ash-colour, with a cast of reddish; the tail, which is of very considerable length, is annulated with distinct circles of black: its most remarkable character is the long, flexible snout, somewhat truncated at the end. By the assistance of this it turns up the earth, in the manner of a hog, in quest of earth-worms, &c. Like the polecat, it also preys on the smaller quadrupeds, birds, &c. It is a native of South America, and seems to have been first described by Marcgrave in his History of Brasil. There is a particularity sometimes observable in this animal, which seems worthy of notice, viz. a kind of prolongation of the skin at the back of the heel into several horny processes, of about a quarter of an inch in length: these in some specimens are scarcely visible. The tongue is marked on the upper part with several furrows, so disposed as to resemble the fibres of a leaf.

4. Viverra vulpecula. Coasse. This animal is about the size of the polecat, measuring 18 inches from nose to tail; the tail is long and full of hair: the whole animal is of a deep or blackish chocolate-colour, but the tail is sometimes mixed with white. It is a native of Mexico and many other parts of America, and possesses the power of emitting, when attacked or irritated, such powerfully offensive effluvia, as, in most instances, effectually to discomfit and repel its pursuers.

5. Viverra striata. Striated weesel. It has been imagined, and not without a degree of probability, that this animal is the female of viverra vulpecula, or coasse. It is of the same size and general aspect, but is distinguished by five parallel longitudinal white stripes on the back; the tail is very bushy or full of hair. In the different specimens of this animal there is some slight variation observable in the proportion of the dorsal stripes, as well as in the colour of the tail, which is sometimes marked with a pair of lateral white bands, and sometimes almost entirely white. Its manners and horrible vapour, when irritated, perfectly agree with the viverra vulpecula; and the same description of this offensive quality may be applied to this and some other species. If the accounts given of this odious vapour are not aggravated by the abhorrent recollection of those who have experienced its effects, every other ill smell which nature can produce is surpassed by the overpowering fœtor of these extraordinary quadrupeds. In consequence of the dreadful emanation, the dogs are said to relinquish their pursuit, and the men to fly with precipitation from the tainted spot; but if unfortunately the least particle of the fluid which the animal commonly discharges at this juncture, should happen to light on the clothes of the hunter, he becomes a general nuisance wherever he appears, and is obliged to divest himself of his dress, and practise all the arts of ablution, in order to be restored to the society of mankind.

To add to the history of these strange circumstances, it is affirmed that the animal is sometimes tamed, and rendered domestic; in which state it is pretended that it never emits its pestilential vapour, unless greatly displeased or irritated: if this is the case, it ought surely to be treated, as an eminent zoologist has well observed, with the highest attention.

6. Viverra capensis. The Cape weesel, is one of the larger animals of the genus, measuring two feet from nose to tail, which is eight inches long. Its colour is a cinereous grey above, and brownish black below; the two colours being separated along the whole length of the animal, from the base of the tail, by a stripe of black and white; the ears are scarcely visible; the tail rather thick; the legs short, and the head large; the snout short and somewhat pointed; the body seems of a thicker form than is usual in this genus.

This animal, when pursued, ejects a fetid liquid, accompanied by a smell as insufferable as that of some of the American weesels or skunks, and productive of the same effects.

7. Viverra civetta. Civet. The viverra civetta, commonly known by the name of the civet-cat, is a native of several parts of Africa and India. The general length of this animal, from nose to tail, is something more than two feet, and the tail measures fourteen inches. The ground colour of the body is yellowish ash-grey, marked with large blackish, or dusky spots, disposed in longitudinal rows on each side, and sometimes a tinge of ferruginous appears intermixed; the hair is coarse, and along the top of the back stands up, so as to form a sort of mane; the head is of a lengthened or sharpish form, with short rounded ears; the eyes are of a bright sky-blue; the tip of the nose black; the sides of the face, chin, breast, legs, and feet, are black; the remainder of the face, and part of the sides of the neck, are of a yellowish white; from each ear are three black stripes, terminating at the throat and shoulders; the tail is generally black, but sometimes is marked with pale or whitish spots on each side the base. It is an animal of a wild disposition, and lives in the usual manner of others of this genus, preying on birds, the smaller quadrupeds, &c. It is remarkable for the production of the drug called civet (sometimes erroneously confounded with musk). This substance is a secretion formed in a large double glandular receptacle, situated at some little distance beneath the tail, and which the animal empties spontaneously. When the civet-cats are kept in a state of confinement (as is usual with the perfumers at Amsterdam and other places), they are placed, from time to time, in strong wooden cages or receptacles, so constructed as to prevent the creature from turning round and biting the person employed in collecting the secreted substance; this operation is said to be generally performed twice a week, and is done by scraping out the civet with a small spatula, or spoon. This substance is of a yellowish colour, and of the consistence of an unguent; of an extremely strong and even unpleasant odour when fresh, so as sometimes to cause giddiness and head-ache, but becomes more agreeable by keeping: the quantity obtained each time amounts to about a dram.

Civet, though an article in the more antient materia medica, and though still employed by the Oriental physicians, is with us chiefly used in perfumes. It has a very fragrant smell, and a subacrid taste; it unites readily with oils, both expressed and distilled; in watery or spiritous menstrua it does not dissolve, but impregnates the fluids strongly with its odour. It may, however, be made to unite with, or be soluble in, water, by means of rubbing with mucilages.

8. Viverra zibetha. Zibet. This, which was figured as a variety by Gesner, and more precisely discriminated by Buffon, seems to be considered by modern naturalists as a distinct species. The zibet is chiefly found in India and the Indian islands. Its general aspect is the same with the former species, but its snout is somewhat sharper, and its tail longer. In short, this species may be called the Indian, and the former the African, civet-cat. In disposition and manners they both seem to agree; as well as in the secretion of the perfume before described, which is collected from both animals in the same manner.

9. Viverra genetta. The genet is one of the most beautiful animals of this genus. It is about the size of a very small cat, but is of a longer form, with a sharp-pointed snout, upright ears, slightly pointed, and very long tail. The colour of the genet is commonly a pale-reddish grey, with a black or dusky line running along the back, where the hair is rather longer than on the other parts, and forms the appearance of a very slight mane; along the sides of the body run several rows of roundish black spots, which sometimes incline a little to a squarish form; the muzzle is dusky; beneath each eye is a white spot; the cheeks, sides of the neck, and the limbs, are spotted in a proportionally smaller pattern than the body, and the tail is annulated with black.

The genet is an animal of a mild disposition, and easily tamed. In various parts of the East, as well as at Constantinople, it is domesticated like the cat, and is said to be equal, or superior, to that animal in clearing houses from rats or mice. It is a cleanly animal, and has a slight musky smell. It is a native of the western parts of Asia, but is said likewise to occur in Spain, and even occasionally in some parts of France.

10. Viverra fossa. The fossane appears to be so nearly allied to the genet, that it might almost pass for a variety of that animal. This animal is a native of Madagascar, Guinea, Bengal, Cochinchina, and the Philippine islands. It is said to be possessed of considerable fierceness, and to be with difficulty tamed. It destroys poultry in the manner of the common weesel. When young, it is said to be good food. Its size is that of the genet. See Plate Nat. Hist. fig. 419.

11. Viverra caudivolvula. Prehensile weesel. This animal, having a prehensile tail, is nineteen inches in length from the nose to the tail, which is seventeen inches long. The nose is short and dusky; the eyes small; the ears short, broad, and flapping, and placed at a great distance from each other; the head flat and broad; the cheeks swelling out; the tongue very long; the legs and thighs short and thick, with five toes to each foot; claws large, slightly hooked, and flesh-coloured. Its colour yellow, shaded with dusky. A blackish or dusky list runs down the back from head to tail, and a similar one half way down the belly. This animal is of gentle manners, active and playful, and hangs by its tail occasionally, in the manner of the prehensile-tailed monkeys. It is supposed to be a native of Jamaica.

12. Viverra foina. The marten is an animal of a highly elegant appearance. Its general length, from nose to tail, is about a foot and a half, and the tail is ten inches long. The marten is of a blackish tawny colour, with a white throat; and the belly is of a dusky brown; the tail is bushy, or full of hair, and of a darker colour than the other parts; the ears are moderately large and rounded, and the eyes lively. This animal is a native of most parts of Europe; inhabiting woods and fields, and preying on birds and other small animals. If taken young, it may be easily tamed, and even rendered domestic. It breeds in the hollows of trees, and brings forth from three to five young. The skin is used as a fur.

13. Viverra zibellina. The sable is greatly allied to the marten in its appearance, but has a longer or sharper head, and more lengthened ears. Its general colour is a deep glossy brown; the hair being ash-coloured at the roots and black at the tips; the chin is cinereous, and the edges of the ears yellowish. Its size is equal to that of the marten; but, exclusive of other differences, a principal one consists in the tail, which is much shorter in proportion than in the marten. The sable is an inhabitant of the northern parts of Asia, and is an extremely important article in the fur-trade. It principally lives in holes under ground, especially under the roots of trees, and sometimes, like the marten, forms its nest in the hollows of trees. It is an active, lively animal, preying, in the manner of the marten, on the smaller quadrupeds, birds, &c. Like the marten, it is also most lively during the night, and sleeps much by day. In autumn the sable is said to eat cranberries, whortles, &c. It brings forth early in the spring, and has from three to five young at a time. The chase of the sable, according to Mr. Pennant, was, during the more barbarous periods of the Russian empire, the principal task of the unhappy exiles who were sent into Siberia, and who, as well as the soldiers sent there, were obliged to furnish, within a given time, a certain quantity of furs; but as Siberia is now become more populous, the sable have in a great measure quitted it, and have retired farther to the north and east, into the desert, forests, and mountains.

Sables are numbered among the most valuable of furs. From an abstract drawn up by the late Dr. Forster, from Muller's account of its commercial history, it appears that the price varies, from one to ten pounds sterling and above. The blackest, and those which have the finest bloom or gloss, are reputed the best. The very best are said to come from the environs of Nertchisk and Yakutsk, and in this latter district the country about the river Ud sometimes affords sables of which a single fur is sold, at the rate of sixty or seventy rubles, or twelve or fourteen pounds sterling. Sometimes the furs of sables are fraudulently dyed, and otherwise prepared, in order to give them a more intense colour, but these are very inferior to the fine natural ones, and are distinguishable by a kind of withered or dull appearance of the hair itself when accurately inspected.

The sable occurs in North America, as well as in Asia; the American sables are said to be chiefly of a chesnut-colour, and more glossy, but coarser, than the Siberian sables. It is necessary to observe, that the sable varies in its cast of colour at different seasons and in different districts; instances have been known, though rarely, of its being found perfectly white.

14. Viverra putorius. The polecat is one of the most remarkable European species of the weesel tribe. Its colour is an extremely deep blackish-brown, with a tawny cast slightly intermixed; the ears are edged with white, and the space round the muzzle is also whitish. The general length of this animal is seventeen inches, exclusive of the tail, which measures about six inches. The polecat is found in most parts of Europe, as well in some of the Asiatic regions, as in Siberia, where it is said to be generally found with the rump of a whitish or yellowish tinge, surrounded with black.

The polecat commonly forms itself a subterraneous retreat, sometimes beneath the roots of large trees, and sometimes under hay-ricks, and in barns. It preys indiscriminately on the smaller animals, and is very destructive to poultry: it is also, like the ferret, a cruel enemy to rabbits, which it destroys by sucking their blood, instead of tearing them immediately in pieces. It steals into barns, pigeon-houses, &c. where it occasionally makes great havock; biting off the heads of fowls and pigeons, and then carrying them away to its retreat; and sometimes it carries off the heads alone. During the summer, however, it principally frequents rabbit-warrens, or the hollow trunks of trees, &c. &c. and prowls about in quest of young birds, rats, field-mice, &c. According to the count de Buffon, a single family of polecats is sufficient to destroy a whole warren of rabbits; and he observes, that this would be a simple method of diminishing the number of rabbits where they are too abundant. In Spain the ferret is said to have been formerly introduced for a similar purpose. The polecat also preys occasionally on fish, of which a curious instance is recorded in Mr. Bewick's History of Quadrupeds. During a severe storm, one of these animals was tracked in the snow from the side of a rivulet to its hole, at some distance from it; as it was observed to have made frequent trips, and as other marks were seen in the snow, which could not easily be accounted for, it was thought a matter worthy of more diligent enquiry; its hole was accordingly examined, the animal taken, and eleven fine eels were discovered to be the fruits of its nocturnal excursions; the unusual marks in the snow having been made by the motion of the eels while dragged along in the animal's mouth. That the polecat, however, sometimes feeds in this manner, is, in reality, no new observation; since Aldrovandus assures us that it will occasionally take up its residence in the hollow banks of rivulets, in order to lie in wait for, and prey upon, fish. The polecat is also delighted with milk, and will visit the dairy, in order to indulge in this article. It has been known to attack bee-hives in the winter season, and to feed on the honey. The spring is the season in which it breeds; the female producing three or four at a birth, which she is said to suckle but a short time, accustoming them early to suck the blood of the animals which she brings to them, as well as eggs, &c.

The polecat has been known to breed with the ferret; and it is said to be a practice with warreners, who keep these animals, to procure a mixed breed from time to time, which are of a colour between the ferret and the polecat, or of a dingy yellowish-brown.

The polecat is a strong and active creature, and will spring with great vigour and celerity when preparing to attack its prey, or to escape from pursuit, at which time it arches its back considerably, in order to assist its effort. It is of a smell proverbially fetid, being furnished, like several others of the weesel tribe, with certain receptacles which secrete a thickish fluid of a peculiarly strong and offensive odour. The fur, however, is beautiful, and the skin, when properly dressed, is numbered among the commercial furs, and used for tippets and other articles of dress. It is added by Aldrovandus, that the furriers endeavour to obtain skins taken from such animals as have been killed during the winter, as being far less fetid than those killed in the spring and summer.

15. Viverra fero. Ferret. Of similar manners to the polecat is the ferret, the natural history of which has been so well detailed by the count de Buffon, that it is scarcely possible to add any thing material to that elegant author's description. The ferret in general form resembles the polecat, but is a smaller animal; its usual length being about fourteen inches, exclusive of the tail, which is about five. Linnæus, in the twelfth edition of the Systema Naturæ, seems to entertain a doubt whether it is truly distinct from the polecat; it is, however, a native of Africa, and not of Europe, and supports with difficulty the cold of an European winter; whereas the polecat is found not only in the temperate, but also in the colder parts of the European regions; to which may be added, that, exclusive of its smaller size, it is of a more slender shape, and the snout is sharper in proportion than in the former animal. The ferret is used for rabbit-hunting in preference to the polecat, because it is more easily tamed; but it is necessary to keep it in a warm box, with wool, or some other substance, in which it may imbed itself. It sleeps almost continually, and when awake, immediately begins to search about for food: it is usually fed with bread and milk; but its favourite food is the blood of the smaller animals. It is by nature an enemy to the rabbit; and it is affirmed by Buffon, that whenever a dead rabbit is presented for the first time to a young ferret, he flies upon it in an instant, and bites it with great fury; but if it is alive, he seizes it by the throat, and sucks its blood. When let into the burrows of rabbits, the ferret is always muzzled, that it may not kill the rabbits in their holes, but only drive them out, in order to be caught in the nets. If the ferret is put in without a muzzle, or happens to disengage himself from it, he is often lost; for after sucking the blood of the rabbit, he falls asleep, and cannot be regained, except sometimes by smoking the hole, in order to oblige him to come out; but as this is a practice which does not always succeed, it continues to lead a rapacious and solitary life in the warren, as long as the summer continues, and perishes by the cold of the winter.

We are told by Strabo that the ferret was brought into Spain from Africa: and it is supposed that this was done in order to free that country from the vast number of rabbits with which it was over-run; and from Spain it was gradually introduced into other European countries. The ferret is an animal of an irascible nature, and, when irritated, his odour, which is at all times disagreeable, becomes far more so than usual. The general colour of the ferret is a very pale yellowish-brown, or cream-colour; and the eyes are of a bright and lively red.

16. Viverra vulgaris. The common weesel, is one of the smallest species in this numerous tribe of quadrupeds. Its general length is about seven inches, exclusive of the tail, which measures near two inches and a half. Its colour is a pale reddish, or yellowish-brown, and beneath it is entirely white; but below the corners of the mouth, on each side, is a brown spot: the ears are small and rounded, and the eyes are black. This little animal is possessed of a considerable degree of elegance in its aspect, and its motions are light and easy; but it has the same unpleasant smell with the stoat, and some other species. It is an inhabitant of the cavities under the roots of trees, as well as of banks near rivulets, &c. from which it occasionally sallies out in quest of birds, field-mice, &c. It even attacks young rabbits, and other animals of far superior size to itself; but its chief prey, at least in this country, seems to be the field-mouse, of which it destroys great multitudes. From the extreme flexibility of its body, and its wonderful activity, it readily ascends the sides of walls, and by this means pursues its prey into the most distant retirements; and is a frequent inhabitant of barns and granaries. The weesel produces four or five young at a time; preparing for them a bed of moss, grass, &c. An instance is given by the count de Buffon of a weesel's nest being found in the carcase of a wolf, which had been hung up near a wood; the nest was made in the cavity of the thorax. The count de Buffon, in his first description of the weesel, affirmed that it was a perfectly untameable animal; but he afterwards received very authentic accounts of weesels which had been so completely tamed as to exhibit every mark of attachment to their benefactors, and to be as familiar as a cat or lap-dog. An account of this kind is given by one of his correspondents in the seventh supplemental volume of his Natural History, which amply confirms the truth of this; and among other curious particulars, it is observed, that when asleep, the muscles of this little animal are in a state of extreme flaccidity, so that it may be taken up by the head, and swung backwards and forwards, in the manner of a pendulum, several times, before it wakes.

17. Viverra erminea. Stoat. This animal much resembles the weesel in its general appearance, as well as in colour, but is considerably larger; the body, exclusive of the tail, measuring ten inches, and the tail five and a half; the tip of the tail is also constantly black, whatever may be the gradation or cast of colour on the body; for the stoat, in the northern regions, becomes milk-white during the winter, in which state it is commonly called the ermine. It is sometimes found of this colour in our own country; and instances are not very uncommon in which it appears parti-coloured, or white in some parts and brown in others, the change of colour having not been completed. Its smell is strong and unpleasant. The stoat is similar in its manners to the weesel, living in hollows under the roots of trees, in banks near rivulets, &c. and preying on all manner of smaller animals, as well as on rabbits, &c. It does not, however, like the weesel, visit houses, but confines itself to the fields. It is an inhabitant both of the northern part of Europe and of Asia. It occurs in Kamtschatka and the Kurile isles. It is also said to be found in several parts of North America.

In Norway and in Siberia the skins are a great article of commerce; most of the ermines or white stoat-skins being brought thence. In Siberia the stoat is said to be found in the birch forests, but not in the pine forests; and the skins are sold on the spot, according to Mr. Pennant, at from two to three pounds sterling per hundred. The animals are either taken in traps or shot with blunt arrows.

18. Viverra maculata. Spotted weesel. This, which is described in governor Phillips's Voyage to Botany Bay, is said to be of the size of a large polecat, measuring 18 inches from nose to tail, and the tail nearly as much; and the visage is of a pointed shape. The colour is said to be black, marked all over, the tail not excepted, with irregular blotches of white; the tail is represented as thin, and gradually tapering to the end; the whiskers very long, and the general apparance of the animal such as to resemble the viverrine opossum in most particulars, except in the appearance of the tail.

VIVIPAROUS, in natural history, an epithet applied to such animals as bring forth their young alive and perfect, in contradistinction to those that lay eggs, which are called oviparous animals.

ULCER. See Surgery.

ULLAGE, in gauging, is so much of a cask, or other vessel, as it wants of being full. See Gauging.

ULMUS, a genus of plants of the class pentandria, and order digynia, and in the natural system arranged under the 53d order, scabridæ. The calyx is quinqued; there is no corolla. The fruit is a dry, compressed, membranaceous berry. There are six species, two of which are natives of Britain, viz. the campestris, common elm, and the montana, or wych elm. All the sorts of elm may be either propagated by layers or suckers taken from the roots of the old trees, the latter of which is generally practised by the nursery-gardeners; but as these are often cut up with indifferent roots, they often miscarry, and render the success doubtful; whereas those which are propagated by layers are in no hazard, and always make better roots, and come on faster, than the other, and do not send out suckers from their roots in such plenty, for which reason this method should be more universally practised. The elm delights in a stiff, strong soil. It is observable, however, that here it grows comparatively slow. In light land, especially if it is rich, its growth is very rapid; but its wood is light, porous, and of little value, compared with that which grows upon strong land, which is of a closer, stronger texture, and at the heart will have the colour, and almost the heaviness and the hardness, of iron. On such soils the elm becomes profitable, and is one of the trees which ought, in preference to all others, to engage the planter's attention.

ULNA. See ANATOMY.

ULVA, a genus of plants of the class cryptogamia, and order of algæ. The fructification is inclosed in a diaphanous membrane. There are 26 species of British plants. They are all sessile, and without roots, and grow in ditches, and on stones along the sea-coast. None of them are applied to any particular use different from the rest of the algæ, except the umbilicalis, which in England is pickled with salt, and preserved in jars, and afterwards stewed and eaten with oil and lemon juice. This species, called in English the navel laver, is flat, orbicular, sessile, and coriaceous.

UMBELLÆ, *umbels*, among botanists, the round tufts or heads of certain plants set thick together, and all of the same height.

UMBELLIFEROUS PLANTS, are such as have their tops branched and spread out like an umbrella, on each little subdivision of which there is growing a small flower; such are fennel, dill, &c. See BOTANY.

UMBER, or UMBRE, *umbria*, among painters, &c. a kind of dry dusky-coloured earth, which, diluted with water, serves to make a dark-brown colour, usually called with us a hair-colour. It is called umber, from umbra, a shadow, as serving chiefly for the shading of objects; or, perhaps, from Umbria a country of Italy, whence it used to be brought.

UMBER, or *grayling*, in ichthyology. See SALMO.

UNCARIA, a genus of plants of the class and order pentandria monogynia. The corolla is salver-shaped; germ. crowned with a gland; stigma two-grooved; peric. two-celled, many-seeded. There are two species.

UNCIA, in general, a Latin term denoting the twelfth part of any thing, particularly the twelfth part of a pound, called in English an ounce; or the twelfth part of a foot, called an inch. See MEASURE, and WEIGHT.

UNCIÆ, in algebra, the numbers prefixed before the letters of the members of any power produced from a binomial, residual, or multinomial root. Thus, in the fourth power of $a+b$, viz. $a^4+4a^3b+6a^2b^2+4ab^3+b^4$, the unciæ are 4, 6, and 4, being the same with what others call co-efficients. See ALGEBRA.

UNDECAGON, is a polygon of eleven sides. If the side of a regular undecagon is 1, its area will be $9{,}3656399 = \frac{11}{4} \times$ tang. of $73\frac{7}{11}$ degrees; and therefore if this number is multiplied by the square of the side of any other regular undecagon, the product will be the area of that undecagon.

UNGUIS. See ANATOMY.

UNGULA, in geometry, is a part cut off a cylinder, cone, &c. by a plane passing obliquely through the base, and part of the curve surface, so called from its resemblance to the (ungula) hoof of a horse, &c.

UNICORN-FISH. See MONODON.

UNIOLA, a genus of the triandria digynia class of plants, the corolla whereof consists of a bivalve glume; the valves are of a lanceolate-compressed figure, like those of the cup; the inner valve appears somewhat higher than the outer one; the corolla performs the office of a pericarpium, inclosing the seed, which is single, and of an ovated oblong figure. There are three species.

UNISON, in music, that consonance, or coincidence of sounds, proceeding from an equality in the number of vibrations made in a given time by two sonorous bodies; or the union of two sounds so directly similar to each other in respect of gravity, or acuteness, that the ear perceiving no difference, receives them as one and the same.

The antients were much divided in opinion respecting the question whether the unison is a consonance. Aristotle speaks in the negative; Muris Mersennus, and others, declare in the affirmative. The decision of the question, however, depends on the definition we give to the word consonance. If by a consonance we only understand two or more sounds agreeable to the ear, the unison is a consonance; but if we include in the consonance sounds of a different pitch, *i. e.* sounds less or more acute with respect to each other, the unison, by its own definition, is not a consonance.

UNISONI, (Ital. plu.,) a word implying that the parts in a score over which it is written, are in unison with each other; as violini unisoni, the violins in unison; flauti unisoni, the flutes in unison.

UNITY. See POETRY.

UNONA, a genus of the polyandria polygamia class and order of plants. The calyx is three-leaved, six-petals; berries two or three seeded. There are four species, trees of the East and West Indies.

UNXIA, a genus of plants of the class and order syngenesia polygamia superflua. The calyx is five-leaved, leaflets ovate; florets of disk and ray five, recept. naked. There is one species.

VOID AND VOIDABLE, in the law. Some things are absolutely void, and others only voidable. A thing is void which is done against law at the very time of doing it, and no person shall be bound by such an act; but a thing is only voidable which is done by a person who ought not to have done it, but who, nevertheless, cannot avoid it himself after it is done; though it may be by some act in law made void by his heir, &c. 2 Lil. Abr. 807.

VOLCANO, in natural history, a burning mountain, or one that occasionally vomits forth fire, flame, ashes, cinders, &c. Volcanoes are peculiar to no climate, and have no necessary connection with any other mountains, but seem to have some with the sea, being generally in its neighbourhood; they frequently throw out matters which belong to the sea, as the relics of fishes, sea-weed, and sometimes sea-water itself. Sir William Hamilton observes in the Phil. Trans. for 1776, that "the operations of Vesuvius are very capricious and uncertain, except that the smoke increases considerably and constantly when the sea is agitated, and the wind blows from that quarter. Volcanic mountains are of all heights; some, as that of Tanna, so low as 450 feet; Vesuvius is 3600 feet high; and Etna, 11000. They in general form lofty spires; and the volcano itself is internally shaped like an inverted cone, placed on a broader basis. This cone is called the crater, or bowl, and through it the lava generally passes, though sometimes it bursts through the sides, and even proceeds occasionally from the bottom of the mountain. Sometimes the crater falls in, and is effaced; sometimes, in extinguished volcanoes, it is filled with water. Submarine volcanoes have been observed, and from these some islands have derived their origin. Volcanic fires taking place at the bottom of the ocean, would frequently, by the expansive force of the steams which are generated, elevate those parts which were once at the bottom of the deep, and overflow those which were habitable earth. It is conjectured, that subterraneous convulsions operated more powerfully in the early ages of the world than at any later period; and indeed such an hypothesis is supported by the most probable reasoning, since we may well conceive that at the first consolidation of the earth, much heterogeneous matter would be included in the different masses, which might produce more frequent fermentations than at any after periods, when these have been, if we may so express it, purged off by frequent eruptions, and in many parts, perhaps, rectified and assimilated by slow and secret processes in the bowels of the earth. But history was not cultivated till a very late period, and the most eventful ages of nature have passed unrecorded.

The force of subterraneous fires, or rather of the steam which is generated by them, is so great, that considerable rocks have been projected by Vesuvius to the distance of eight miles. A stone was once thrown from the crater of that volcano twelve miles, and fell upon the marquis of Lauro's house at Nola, which it set on fire. One also, which measured twelve feet in height and forty-five in circumference, was carried, in 1767, by the projectile force of the steam, a quarter of a mile from the crater. In an eruption of Etna, a stone, fifteen feet long, was ejected from the crater to the distance of a mile, and buried itself eight feet deep in the ground.

A volcano broke forth in Peru in 1600, accompanied with an earthquake, and the sand and ashes which were ejected covered the fields ninety miles one way, and one hundred and twenty another. Dreadful thunders and lightning were heard and seen for upwards of ninety miles round Araquapa during this eruption, which seemed to denote some connection between the electric matter and these volcanic fires; and this fact is strongly confirmed by the very accurate observations of sir William Hamilton, which we shall afterwards have occasion to notice more at large.

Both the inside of the crater and the base of many volcanoes, consist of lava, either entire or decomposed, nearly as low as the level of the sea; but they finally rest either on granite, as in Peru, or schistus, as the extinguished volcanoes of Hesse and Bohemia, or on limestone, as those of Silesia, mount Vesuvius, &c. No ore is found in these mountains, except that of iron, of which lava contains from twenty to twenty-five parts in the hundred, and some detached fragments of the ores of copper, antimony, and arsenic. Vesuvius ejected, from the year 1779 to 1783, 309,658,161 cubic feet of matter of different kinds; we must therefore conclude the seat of these fires to be several miles below the level of the sea; and as iron makes from one-fourth to one-fifth of these ejections, we may infer that the internal parts of the earth abound much in this metal.

The origin of these subterraneous fires is not easily explained. Iron-filings mixed with powdered sulphur, and the whole moistened with water into a paste, will swell, become hot, and if the quantity is considerable, will throw out a blue flame. It is a mixture of this kind which is used for making an artificial earthquake; for such a quantity of inflammable gas is produced during the fermentation, that if the mass is buried in the earth, the gas will force a passage for its escape, and exhibit, on a small scale, the phenomena of an earthquake. M. Lemery seems to have been the first person who illustrated, in this manner, the origin of volanic fires and earthquakes. He mixed twenty-five pounds of iron-filings with an equal weight of sulphur, and having made them into a paste, with the addition of water, he put them into a pot, covered them with a cloth, and buried them a foot under ground. In about eight or nine hours time the earth swelled, became warm, and cracked, and hot sulphureous vapours were perceived. Now large beds of martial pyrites, sulphuret of iron, are known to exist in different parts of the earth; the only difficulty which attends this explanation of the origin of volcanoes, as well as of earthquakes, is, that the presence of air is in general necessary for the production of actual flame. It is well known, however, that sulphuret of iron, when moistened, acquires heat; and if we suppose it to have been in contact with black wad and petroleum, we may suppose the flame to arise, as we see it produced by art, from the desiccation of the former substance, and its mixture with mineral oil. Many minerals, when heated, afford oxygen gas, a very small quantity of which is sufficient to produce flame; this flame, once produced, may be supported from other ores, and the combustion be maintained by the presence of bituminous schistus, bitumen, and coal. Marl, schistus, horn-stone, schorl, with a further addition of iron, are the true sources of lava. It seems, however, after all, difficult to conceive that such extensive and intense fires should be maintained without the access of considerable quantities of air; that fluid may therefore be possibly supplied by a communication with some extensive caverns, which may themselves receive it by openings at the distance of many miles from the crater of the volcano. It does not seem improbable that the volcanoes, which now burn, may have a communication with the cavities and craters of extinguished volcanoes, and thence derive a supply of air sufficient to account for the inflammation of large beds of pyrites and bituminous matters. M. Buffon supposes, that the seat of volcanic fires is situated but a very little way below the bed of the mountains; but it appears more probable, that it is in general many miles below the surface of the earth, for the quantity of matter discharged from Etna alone is supposed, on a moderate calculation, to exceed twenty times the original bulk of the mountain, and therefore could not have been derived from its contents alone, but must come from the deeper recesses of the earth.

M. Condamine asserts, that all the mountains in the neighbourhood of Naples exhibit undoubted marks of a volcanic origin. He says, he could trace the lava, and other productions of subterraneous fire, from Naples to the very gates of Rome, pervading the whole soil, sometimes pure and sometimes differently combined. "Wherever I see," says he, "on an elevated plain, a circular bason, surrounded with calcined rocks, I am not deceived by the verdure of the adjacent fields; I can discover, beneath the snow itself, the traces of an extinguished fire. If there is a breach in the circle, I usually find out, by following the declivity of the ground, the traces of a rivulet, or the bed of a torrent, which seems as if it was hollowed in the rock, and this rock appears frequently to be pure lava. If the circumference of the bason has no breach, the rain and spring waters, which are collected there, generally form a lake in the very mouth of the volcano." The Appenines, as well as the Cordilleras of Peru and Chili, he supposes to have been a chain of volcanoes. The chain, in both instances, is interrupted, and many of the fires either extinguished or smothered, but many remain still actually burning. This intelligent author is, however, far from attributing to all mountains the same origin; and adds, that in that part of the Alps, which he travelled over, he could observe no such appearances.

The traces of volcanoes have been observed in Ireland by Mr. Whitehurst. Though no visible crater is remaining between Port Rush Strand and Ballycastle eastward, yet, he observes, that whole space, about twenty English miles, is one continued mass of lava. The cliffs, he says, are truly stupendous, and bear every possible mark of having been originally liquid fire. The elevation of that, at the foot of which the Giant's Causeway is situated, he presumes cannot be less than five or six hundred feet perpendicular above the level of the Atlantic ocean, and yet composed entirely of lava; the same appearances extend towards the south upwards of twenty miles.

The most remarkable volcanoes in Europe are Etna and Vesuvius; and as these are not too far distant, we have the most accurate descriptions of them from travellers of the first talents and reputation.

Etna, which is the most striking object in Sicily, and indeed one of the most magnificent productions of nature, rises from an immense base, and mounts equally on all sides to its summit. The ascent on each side is computed at about thirty miles, and the circumference of its base, at one hundred and thirty-three; but as it has never been measured with any great degree of accuracy, its dimensions are but imperfectly known.

The whole mountain is divided into three distinct regions, called La Region Culta, or Piedmontese, the fertile region; La Regiona Sylvosa, or Nemorosa, the woody region; and La Regiona Deserta, or Scoperta, the barren region. These differ as materially both in climate and production as the three zones of the earth, and perhaps with equal propriety might have been styled the torrid, the temperate, and the frigid zone.

The first region of Etna surrounds the base of the mountain, and constitutes the most fertile country in the world on all sides of it, to the extent of fourteen or fifteen miles, where the woody region begins. It is composed almost entirely of lava, which, in time, becomes the most fertile of all soils; but the roads, which are entirely over old lavas, now converted into orchards, vineyards, and corn-fields, are execrable. The lavas, which form this region, arise from a number of beautiful little mountains, every where scattered over the immense declivities of Etna. These are all either of a conical or hemispherical figure, and are in general covered with beautiful trees, and the most luxurious verdure. The formation of them is owing to the internal fires of Etna, which, raging for a vent, at so vast distance from the great crater, that it cannot possibly be carried to the height of twelve or thirteen thousand feet, which is probably the height of the summit of Etna, must necessarily be discharged at some other orifice. After shaking the mountain, and its neighbourhood, for some time, at length the fire bursts open its side, and this is called an eruption. At first it emits only a thick smoke and showers of ashes. These are followed by red-hot stones, and rocks of a great size, which are thrown to an immense height in the air. These stones, together with the quantities of ashes discharged at the same time, form those mountains, which cover all the declivities of Etna. The size of them is in proportion to the duration of the eruption. When it continues a considerable time, it sometimes forms an elevation of one thousand feet in perpendicular height, which at its base is seven or eight miles in circumference.

After the formation of the new mountain, the lava commonly bursts out from its lower side, and, sweeping every thing before it, is generally terminated by the sea. Sometimes it issues from the side of the mountain, without these attending circumstances, which is commonly the case with the eruptions of Vesuvius; in which the elevation being so much smaller, the melted matter is carried up into the crater, where it is dislodged without forming any new mountain, but only adding to the height of the old one; till at length the lava, rising near the summit, bursts the side of the crater. But Etna being upon a much larger scale, one crater is not sufficient to give vent to such immense oceans of liquid fire.

Many striking remains of the great eruption in 1669 are still to be seen, and will long continue as memorials of that dreadful event which overwhelmed Catania, and all the adjacent country. Tremendous earthquakes shook the island, and subterraneous bellowings were heard in the mountain. During some weeks, the sun ceased to appear, and the day seemed changed into night. Borelli, who was a witness to these terrible phenomena, says, that at length a rent, twelve miles in length, was opened in the mountain, in some places of which, when they threw down stones, they could not hear them reach the bottom. Burning rocks, sixty palms in length, were thrown to the distance of a mile, and lesser stones were carried three miles. After the most violent struggles, and a shaking of the whole island, an immense torrent of lava gushed from the rent, and sprung up into the air to the height of sixty palms, whence it poured down the mountain, and overwhelmed every object in its way in one promiscuous ruin.

This destructive torrent, which burst from the side of Etna, at a place called Ricini, rushed impetuously against the beautiful mountain of Montpelieri, and pierced into the ground to a considerable depth; then dividing and surrounding the mountain, it united again on the south side, and poured desolation upon the adjacent country. The progress of the torrent was at first at the rate of seven miles a day, but it afterwards took four days to travel sixteen: wherever it directed its course, the whole appearance of nature was changed, several hills were formed in places which were formerly valleys, and a large lake was so entirely filled up by the melted mass, as not to leave a vestige remaining. In its course it descended upon a vineyard, belonging to a convent of Jesuits, which was formed upon an antient, and probably a very thin, layer of lava, with a number of caverns and crevices under it. The liquid mass entering into these excavations soon filled them up, and by degrees bore up the vineyard, which in a short time, to the great astonishment of the spectators, began to move away, and was carried by the torrent to a considerable distance. In 1770 some remains of this vineyard were still to be seen, but the greater part of it was entirely destroyed.

After destroying several convents, churches, and villages, this fiery current directed its course to Catania, where it poured impetuously over the ramparts, which are near sixty feet in height, and covered up five of its bastions, with the intervening curtains. After laying waste a great part of this beautiful city, and entirely destroying several valuable remains of antiquity, its further progress was stopped by the ocean, over whose banks it poured its destructive current. In its course from the rent in the mountain, till its arrival in the sea, it is said to have totally destroyed the property of near thirty thousand persons. Twenty-four years after the fatal eruption of 1669, a violent earthquake, which extended along all the eastern coast, and destroyed in one hour more than sixty thousand persons, overthrew the remaining buildings of Catania, and buried a very considerable number of its inhabitants under the ruins of their houses and churches.

The celebrated bishop Berkeley has described an eruption of mount Vesuvius, of which he was a witness in the year 1717, and the reader will find his narrative in the first volume of Dr. Goldsmith's History of the Earth and Animated Nature, p. 94. But the most complete and philosophical account of this formidable phenomenon, a volcanic explosion, is that with which sir William Hamilton has favoured the public, in describing the dreadful eruption of that mountain in 1794, and this we shall endeavour to give, as nearly as possible, in his own words.

Sir William begins his narrative with remarking that the frequent slight eruptions of lava for some years past had issued from near the summit, and ran in small channels in different directions down the flanks of the mountain, and from running in covered channels, had often an appearance as if they came immediately out of the sides of Vesuvius, but such lavas had not sufficient force to reach the cultivated parts at the foot of the mountain. In the year 1779, the whole quantity of the lava in fusion having been at once thrown up with violence out of the crater of Vesuvius, and a great part of it falling, and cooling on its cone, added much to the solidity of the walls of this huge natural chimney, and had not of late years allowed of a sufficient discharge of lava to calm that fermentation, which by the subterraneous noises heard at times, and by the explosions of scoriæ and ashes, was known to exist within the bowels of the volcano. The eruptions, therefore, of late years, before this last, were simply from the lava having boiled over the crater, the sides being sufficiently strong to confine it, and oblige it to rise and overflow. The mountain had been remarkably quiet for seven months before the late eruption, nor did the usual vapour issue from its crater, but at times it emitted small clouds of smoke that floated in the air in the shape of little trees. It was remarked by father Antonio di Petrizzi, a Capuchin friar, (who printed an account of the late eruption,) from his convent close to the unfortunate town of Torre del Greco, that for some days preceding this eruption, a thick vapour was seen to surround the mountain, about a quarter of a mile beneath its crater, and it was observed by him and others at the same time that both the sun and the moon had often an unusual reddish cast.

The water of the great fountain at Torre del Greco began to decrease some days before the eruption, so that the wheels of a corn-mill, wrought by that water, moved very slowly; it was necessary in all the other wells of the town and its neighbourhood to lengthen the ropes daily, in order to reach the water; and some of the wells became quite dry. Although most of the inhabitants were sensible of this phenomenon, not one of them seems to have been sensible of the true cause. Eight days also before the eruption, a man and two boys being in a vineyard above Torre del Greco (and precisely on the spot where one of the new mouths opened, whence the principal current of lava that destroyed the town issued), were much alarmed by a sudden puff of smoke which issued from the earth close to them, and was attended with a slight explosion.

Had this circumstance, with that of the subterraneous noises heard at Resina for two days before the eruption (with the additional one of the decrease of water in the wells), been communicated at the time, it would have required no great foresight to have been certain that an eruption of the volcano was near at hand, and that its force was directed particularly towards that part of the mountain.

On the 12th of June 1794, in the morning, there was a violent fall of rain, and soon after the inhabitants of Resina, situated directly over the antient town of Herculaneum, were sensible of a rumbling subterraneous noise, which was not heard at Naples.

From the month of January to the month of May, the atmosphere had been generally calm, and there was continued dry weather. In the month of May there was a little rain, but the weather was unusually sultry. For some days preceding the eruption, the duke della Torre, a learned and ingenious nobleman, who published two letters upon the subject of the eruption, observed by his electrometers, that the atmosphere was charged with an excess of the electric fluid, and thus it continued for several days during the eruption.

About eleven o'clock on the night of the 12th of June, the inhabitants of Naples were all sensible of a violent shock of an earthquake; the undulatory motion was evidently from east to west, and appeared to have lasted near half a minute. The sky, which had been quite clear, was soon after covered with black clouds. The inhabitants of the towns and villages, which are very numerous at the foot of Vesuvius, felt this earthquake still more sensibly, and say, that the shock at first was from the bottom upwards, after which followed the undulation from east to west. This earthquake extended all over the Campagna Felice; and the royal palace at Caserta, which is fifteen miles from Naples, and one of the most magnificent and solid buildings in Europe (the walls being eighteen feet thick), was shaken in such a manner as to cause great alarm, and all the chamber bells rang. It was likewise much felt at Beneventum, about thirty miles from Naples; and at Ariano in Puglia, which is at a much greater distance; both these towns, indeed, have been often afflicted with earthquakes.

On Sunday the 15th of June, soon after ten o'clock at night, another shock of an earthquake was felt at Naples, but did not appear to be quite so violent as that of the 12th, nor did it last so long; at the same moment a fountain of bright fire, attended with a very black smoke and a loud report, was seen to issue, and to rise to a great height, from about the middle of the cone of Vesuvius. Soon after another of the same kind broke out at some little distance lower down; then, as is supposed, by the blowing up of a covered channel full of red-hot lava, it had the appearance as if the lava had taken its course directly up the steep cone of the volcano. Fresh fountains succeeded one another hastily, and all in a direct line, tending, for about a mile and a half, down towards the towns of Resina and Torre del Greco. Sir William Hamilton could count fifteen of them, but believes there were others obscured by the smoke. It seems probable, that all these fountains of fire, from their being in such an exact line, proceeded from one and the same long fissure down the flanks of the mountain, and that the lava and other volcanic matter forced its way out of the widest parts of the crack, and formed there the little mountains and craters that will be described in their proper place. It is impossible that any words can give an idea of the blazing scene, or of the horrid noises that attended this great operation of nature. It was a mixture of the loudest thunder, with incessant reports, like those from a numerous heavy artillery, accompanied by a continued hollow murmur, like that of the roaring of the ocean during a violent storm; and, added to these was another blowing noise, like that of the ascending of a large flight of sky-rockets, or rather like that which is produced by the action of the enormous bellows on the furnace of the Carron iron-foundry in Scotland. The frequent falling of the huge stones and scoriæ, which were thrown up to an incredible height from some of the new mouths, (one of which, having been since measured by the abbé Tata, was found to be ten feet high, and thirty-five in circumference), contributed undoubtedly to the concussion of the earth and air. As the lava did not appear to have yet a sufficient vent, and it was now evident that the earthquakes already felt had been occasioned by the air and fiery matter confined within the bowels of the mountain, and probably at no small depth, considering the extent of those earthquakes, sir William recommended to the company that was with him, who began to be much alarmed, rather to go and view the mountain at some greater distance, and in the open air, than to remain in the house, which was on the sea-side, and in the part of Naples which is nearest and most exposed to Vesuvius. They accordingly proceeded to Posilippo, and viewed the conflagration, now become still more considerable, from the sea-side under that mountain; but whether from the eruption having increased, or from the loud reports of the volcanic explosions being repeated by the mountain behind them, the noise was much louder and more alarming than that they had heard in their first position, at least a mile nearer to Vesuvius. After some time, about two o'clock in the morning of the 16th, it was observed that the lavas ran in abundance, freely, and with great velocity, having made a considerable progress towards Resina, the town which it first threatened, and that the fiery vapours which had been confined had now free vent through many parts of a crack of more than a mile and a half in length, as was evident from the quantity of inflamed matter and black smoke, which continued to issue from the new mouths. Our author therefore concluded that at Naples all danger from earthquakes, which had been his greatest apprehension, was totally removed, and he returned to his former station at St. Lucia near that city.

During all this time there was not the smallest appearance of fire or smoke from the crater on the summit of Vesuvius; but the black smoke and ashes issuing continually from so many new mouths or craters, formed an enormous and dense body of clouds over the whole mountain, and began to give signs of being replete with the electric fluid, by exhibiting flashes of that sort of zig-zag lightning, which in the volcanic language of the country is called ferilli, and which is the constant attendant on the most violent eruptions.

Sir William Hamilton proceeds to remark, that during a thirty years residence at Naples, and during which time he had been witness to many eruptions of Vesuvius, he never before saw the cloud of smoke replete with the electric fire, except in the two great eruptions of 1767, and in that of 1779. The electric fire, in the year 1779, which played constantly within the enormous black cloud over the crater of Vesuvius, and seldom quitted it, was exactly similar to that which is produced, on a very small scale, by the conductor of an electrical machine communicating with an insulated plate of glass, thinly spread over with metallic filings, &c. when the electric matter continues to play over it in zig-zag lines without quitting the surface. He was not sensible of any noise attending that operation in 1779; whereas the discharge of the electrical matter from the volcanic clouds during this eruption, and particularly on the second and third days, caused explosions like those of the loudest thunder; and indeed the storms raised evidently by the sole power of the volcano, resembled in every respect all other thunderstorms; the lightning falling, and destroying every thing in its course. The house of the marquis of Berio at St. Jurio, situated at the foot of Vesuvius, during one of these volcanic storms was struck with lightning, which having shattered many doors and windows, and damaged the furniture, left for some time a strong smell of sulphur in the rooms it passed through. Out of these gigantic volcanic clouds, besides the lightning, the author adds, he had, with many others, both during this eruption, and in 1779, seen balls of fire issue, and some of a considerable magnitude, which bursting in the air, produced nearly the same effect as that from the air-balloons in fireworks; the electric fire, as it came out, having the appearance of the serpents with which those firework-balloons are often filled. The day on which Naples was in the greatest danger from the volcanic clouds, two small balls of fire, joined together by a small link like a chain-shot, fell close to his casino at Posilippo; they separated, and one fell in the vineyard above the house, and the other in the sea, so close to it that he heard the splash in the water. The abbé Tata, in his printed account of this eruption, mentions an enormous ball of this kind which flew out of the crater of Vesuvius while he was standing on the edge of it, and which burst in the air at some distance from the mountain, soon after which he heard a noise like the fall of a number of stones, or of a heavy shower of hail.

About four o'clock in the morning of the 16th, the crater of Vesuvius began to shew signs of being open, by some black smoke issuing out of it; and at day-break another body of smoke, tinged with red, issued from an opening near the crater. On the other side of the mountain, and opposite the town of Ottaiano, it became evident that a new mouth had opened, from which a considerable stream of lava issued, and ran with great velocity through a wood, which it burnt; and having run about three miles in a few hours, it stopped before it arrived at the vineyards and cultivated lands. The crater, and all the conical part of Vesuvius, were soon involved in clouds and darkness, and remained so for several days; but above these clouds, although of a great height, fresh columns of smoke were seen from the crater, rising furiously still higher, until the whole mass remained in the usual form of a pine-tree; and in that gigantic mass of heavy clouds the ferilli, or volcanic lightning, was frequently visible, even in the daytime.

About five o'clock in the morning of the 16th, the lava which had first broken out from the several new mouths on the south side of the mountain, had reached the sea, and was running into it, having overwhelmed, burnt, and destroyed, the greatest part of Torre del Greco, the principal stream of lava having taken its course through the very centre of the town.

Soon after the beginning of this eruption, ashes fell thick at the foot of the mountain, all the way from Portici to Torre del Greco; and what is remarkable, although there were not at that time any clouds in the air, except those of smoke from the mountain, the ashes were wet, and accompanied with large drops of water, which to the taste were very salt; the road, which is paved, was as wet as if there had been a heavy shower of rain. These ashes were black and coarse, like the sand of the sea-shore; whereas those which fell there and at Naples some days after, were of a light-grey colour, and as fine as Spanish snuff, or powdered bark. They contained many saline particles; and those ashes which lay on the ground, exposed to the burning sun, had a coat of the whitest powder on their surface, which to the taste was extremely salt and pungent.

By the time that the lava had reached the sea, between five and six o'clock in the morning of the 16th, Vesuvius was so completely involved in darkness, that the violent operation of nature which was going on there could no longer be discerned, and so it remained for several days; but the dreadful noise, and the red tinge on the clouds over the top of the mountain, were evident signs of the activity of the fire underneath. The lava ran but slowly at Torre del Greco after it had reached the sea; and on the 17th of June in the morning, its course was stopped; excepting that at times a little rivulet of liquid fire issued from under the smoking scoriæ into the sea, and caused a hissing noise, and a white smoke; at other times a quantity of large scoriæ were pushed off the surface of the body of the lava into the sea, discovering that it was red-hot under that surface. Even to the latter end of August the centre of the thickest part of the lava that covered the town retained its red heat. The breadth of the lava that ran into the sea, and formed a new promontory there, after having destroyed the greatest part of the town of Torre del Greco, having been exactly measured by the duke della Torre, is 1204 English feet. Its height above the sea is twelve feet, and as many feet under water; so that its whole height is twenty-four feet: it extends into the sea 626 feet. The sea-water was boiling as in a cauldron, where it washed the foot of this new-formed promontory.

The rapid progress of the lava, however, was such, after it had altered its course from Resina, which town it first threatened, and had joined a fresh lava that issued from one of the new mouths in a vineyard, about a mile from the town, that it ran like a torrent over the town of Torre del Greco, allowing the unfortunate inhabitants scarcely time to save their lives. Their goods and effects were totally abandoned; and indeed several of the inhabitants, whose houses had been surrounded with lava while they remained in them, escaped from them, and saved their lives the following day, by coming out of the tops of their houses, and walking over the scoriæ on the surface of the red-hot lava. The lava over the cathedral, and in other parts of the town, is said to be upwards of forty feet in thickness; the general height of the lava during its whole course was about twelve feet, and in some parts not less than a mile, in breadth.

On Wednesday June 18, the wind having for a short space of time cleared away the thick cloud from the top of Vesuvius, it was now discovered that a great part of its crater, particularly on the west side opposite Naples, had fallen; in which it probably did about four o'clock in the morning of that day, as a violent shock of an earthquake was felt at that moment at Resina, and other parts at the foot of the volcano. The clouds of smoke, mixed with the ashes, were of such a density as to appear to have the greatest difficulty in forcing their passage out of the now widely-extended mouth of Vesuvius, which, since the top fell in, is described as not much short of two miles in circumference. One cloud heaped on another, and succeeded one another incessantly, formed in a few hours such a gigantic and elevated column of the darkest hue over the mountain, as seemed to threaten Naples with immediate destruction; having at one time been bent over the city, and appearing to be much too massive and ponderous to remain long suspended in the air. It was, besides, replete with the ferilli, or volcanic lightning, which was stronger than common lightning; just as Pliny the Younger describes it in one of his letters to Tacitus, when he says "fulgoribus illæ et similes et majores erant."

Vesuvius was at this time completely covered, as were all the old black lavas, with a thick coat of those fine light-grey ashes already fallen, which gave it a cold and horrid appearance; and in comparison of the enormous mass of clouds (which certainly, however it may contradict our idea of the extension of our atmosphere, rose many miles above the mountain), it appeared like a molehill, although the perpendicular height of Vesuvius, from the level of the sea, is more than three thousand six hundred feet. The abbé Braccini, as appears in his printed account of the eruption of mount Vesuvius in 1631, measured with a quadrant the elevation of a mass of clouds of the same nature, which was formed over Vesuvius during that great eruption, and found it to exceed thirty miles in height. Dr. Scotti, in his printed account of this eruption, says that the height of this threatening cloud of smoke and ashes, measured from Naples, was found to be of an elevation of thirty degrees.

The laudable curiosity of our author induced him to go upon mount Vesuvius, as soon as it was consistent with any degree of prudence, which was not until the 30th of June, and even then it was attended with some risk. The crater of Vesuvius, except at short intervals, had been continually obscured by the volcanic clouds from the 16th; and was so on that day, with frequent flashes of lightning playing in those clouds, and attended as usual with a noise like thunder; and the fine ashes were still falling on Vesuvius, but still more on the mountain of Somma. Sir William went up the usual way by Resina, and observed, in his way through that village, that many of the stones of the pavement had been loosened, and were deranged by the earthquakes, particularly by that of the 18th, which attended the falling in of the crater of the volcano, and which had been so violent as to throw many people down, and obliged all the inhabitants of Resina to quit their houses hastily, to which they did not dare to return for two days. The leaves of all the vines were burnt by the ashes that had fallen on them; and many of the vines themselves were buried under the ashes, and great branches of the trees that supported them had been torn off by their weight. In short, nothing but ruin and desolation was to be seen. The ashes at the foot of the mountain were about ten or twelve inches thick on the surface of the earth; but in proportion as he ascended, their thickness increased to several feet, not less than nine or ten in some parts; so that the surface of the old rugged lavas, which before was almost impracticable, was now become a perfect plain, over which he walked with the greatest ease. The ashes were of a light-grey colour, and exceedingly fine, so that by the footsteps being marked on them as on snow, he learnt that three small parties had been up before him. He saw likewise the track of a fox, which appeared to have been quite bewildered, to judge from the many turns he had made. Even the traces of lizards and other little animals, and of insects, were visible on these fine ashes. Sir William and his companion ascended to the spot whence the lava of the 15th first issued, and followed the course of it, which was still very hot (although covered with such a thick coat of ashes) quite down to the sea at Torre del Greco, which is more than five miles. It was not possible to get up to the great crater of Vesuvius, nor had any one yet attempted it. The horrid chasms that existed from the spot where the late eruptions first took place, in a straight line for near two miles towards the sea, cannot be imagined. They formed valleys more than two hundred feet deep, and from half a mile to a mile wide; and where the fountains of fiery matter issued during the eruption, were little mountains with deep craters. Ten thousand men, in as many years, could not make such an alteration on the face of Vesuvius. Except the exhalations of sulphureous vapours, which broke out from different spots of the line above-mentioned, and tinged the surface of the ashes and scoriæ in those parts with either a deep or pale yellow, with a reddish ochre-colour, or a bright white, and in some parts with a deep green and azure blue (so that the whole together had the effect of an iris), all had the appearance of a sandy desert. Our adventurers then went on the top of seven of the most considerable of the new-formed mountains, and looked into their craters, which on some of them appeared to be little short of half a mile in circumference; and although the exterior perpendicular height of them did not exceed two hundred feet, the depth of their inverted cone within was three times as great. It would not have been possible to have breathed on these new mountains near their craters, if they had not taken the precaution of tying a double handkerchief over their mouths and nostrils; and even with that precaution they could not resist long, the fumes of the sulphureous acid were so exceedingly penetrating, and of such a suffocating quality. They found in one a double crater, like two funnels joined together; and in all there were some little smoke and deposition of salts and sulphurs, of the various colours above-mentioned, as is commonly seen adhering to the inner walls of the principal crater of Vesuvius.

Two or three days after they had been there, one of the new mouths into which they had looked, suddenly made a great explosion of stones, smoke, and ashes, which would certainly have proved fatal to any person who might unfortunately have been present at the time of the explosion. While they were on the mountain, two whirlwinds, exactly like those that form water-spouts at sea, made their appearance; and one of them, which was very near, made a strange rushing noise; and having taken up a great quantity of the fine ashes, formed them into an elevated spiral column, which, with a whirling motion and great rapidity, was carried towards the mountain of Somma, where it broke and was dispersed. One of our author's servants, employed in collecting of sulphur, or sal ammoniac, which crystallizes near the fumaroli as they are called (which are the spots whence the hot vapour issues out of the fresh lavas), found to his great surprise, an exceeding cold wind from a fissure very near the hot fumaroli, upon his leg. In a vineyard not in the same line with the new-formed mountains just described, but in a right line from them, at the distance of little more than a mile from Torre del Greco, they found three or more of these new-formed mountains with craters, out of which the lava flowed; and by uniting with the streams that came from the higher mouths, and adding to their heat and fluidity, enabled the whole current to make so rapid a progress over the unfortunate town.

In the town of Somma, our author found four churches and about seventy houses without roofs, and full of ashes. The great damage on that side of the mountain, by the fall of the ashes and the torrents, happened on the 18th, 19th, and 20th of June, and on the 12th of July. The 19th, the ashes fell so thick at Somma, that unless a person kept in motion, he was soon fixed to the ground by them. This fall of ashes was accompanied also with loud reports, and frequent flashes of the volcanic lightning; so that, surrounded by so many horrors, it was impossible for the inhabitants to remain in the town, and they all fled; the darkness was such, although it was mid-day, that even with the help of torches it was scarcely possible to keep in the high road. On the 16th of July, signor Guiseppe Sacco went up to the crater; and, according to his account, which was printed at Naples, the crater is now of an irregular oval form, and as he supposes (not having been able to measure it) of about a mile and a half in circumference; the inside, as usual, in the shape of an inverted cone, the inner walls of which on the eastern side are perpendicular; but on the western side of the crater, which is lower, the descent was practicable, and Sacco with some of his companions actually went down one hundred and seventy-six palms; from which spot having lowered a cord with a stone tied to it, they found the whole depth of the crater to be about five hundred palms. Such observations, however, on the crater of Vesuvius, are of little consequence, as both its form and apparent depth are subject to great alterations from day to day.

On the 22d of July, one of the new craters, which is the nearest to the town of Torre del Greco, threw up both fire and smoke; which circumstance, added to that of the lava's retaining its heat much longer than usual, seemed to indicate that there was still some fermentation under that part of the volcano. The lava in cooling often cracks, and causes a loud explosion, just as the ice does in the glaciers in Swisserland; such reports were frequently heard at this time at the Torre del Greco; and a vapour was often seen to issue from the body of the lava, and taking fire in the air, fall like those meteors vulgarly called falling stars.

The archbishop of Taranto, in a letter to Naples, and dated from that city the 18th of June, observes: "We are involved in a thick cloud of minute volcanic ashes, and we imagine that there must be a great eruption either at mount Etna or of Stromboli. The bishop did not suspect their having proceeded from Vesuvius, which is about two hundred and fifty miles from Taranto. Ashes also fell, during the late eruption, at the very extremity of the province of Lecce, which is still farther off; and at Martino, near Taranto, a house was struck and much damaged by the lightning from one of the clouds. In the accounts of the great eruption of Vesuvius in 1631, mention is made of the extensive progress of the ashes from Vesuvius; and of the damage done by the ferilli, or volcanic lightning, which attended them in their course."

Our author in this place mentions a very extraordinary circumstance, which happened near Sienna, on the Tuscan state, about eighteen hours after the commencement of the late eruption of Vesuvius on the 15th of June, although he adds, that phenomenon must have no relation to the eruption; it was communicated to him in the following words by the earl of Bristol, bishop of Derry, in a letter dated from Sienna, July 12, 1794: "In the midst of a most violent thunder-storm, about a dozen stones of various weights and dimensions fell at the feet of different people, men, women, and children; the stones are of a quality not found in any part of the Siennese territory; they fell about eighteen hours after the enormous eruption of Vesuvius, which circumstance leaves a choice of difficulties in the solution of this extraordinary phenomenon: either these stones have been generated in this igneous mass of clouds, which produced such unusual thunder; or, which is equally incredible, they were thrown from Vesuvius at a distance of at least two hundred and fifty miles; judge then of its parabola." One of the largest stones, when entire, weighed upwards of five pounds. The outside of every stone that was found, and ascertained to have fallen from the cloud near Sienna, was evidently fresh-vitrified, and black, with indubitable signs of having passed through an extreme heat; when broken, the inside was found of a light-grey colour mixed with black spots, and some shining particles, supposed to be pyrites. Stones of the same nature, at least as far as the eye can judge of them, are frequently found on mount Vesuvius; and should similar stones be found there, with the same vitrified coat on them, the question would be decided in favour of Vesuvius; unless it could be proved that there had been, about the time of the fall of these stones in the Siennese territory, some nearer opening of the earth, attended with an emission of volcanic matter; which might very possibly happen, as the mountain of Radicofani, within fifty miles of Sienna, is certainly volcanic. The celebrated father Ambrogio Soldani, professor of mathematics in the university of Sienna, has printed there a dissertation upon this extraordinary phenomenon: and, it is said, has decided that those stones were generated in the air independantly of volcanic assistance. See METEORIC STONES.

Until after the 7th of July, when the last cloud broke over Vesuvius, and formed a tremendous torrent of mud, which took its course across the great road between Torre del Greco and the Torre dell' Annunziata, and destroyed many vineyards, the eruption could not be said to have finished, although the force of it was over the 22d of June. The power of attraction in mountains is well known; but whether the attractive power of a volcanic mountain is greater than that of any other mountain, is a question. During this eruption, however, it appeared that every watery cloud was evidently attracted by Vesuvius, and the sudden dissolution of those clouds left marks of their destructive power on the face of the country all round the basis of the volcano. After the mouth of Vesuvius was enlarged, our author says he has seen a great cloud passing over it, which not only was attracted, but even sucked in, and disappeared in a moment.

After every violent eruption of mount Vesuvius, we read of damage done by a mephitic vapour; which proceeding from under the ancient lavas, insinuates itself into low places, such as the cellars and wells of the houses situated at the foot of the volcano. After the eruption of 1767, there were several instances, as in this, of people, going into their cellars at Portici, and other parts of that neighbourhood, having been struck down by this vapour, and who would have expired if they had not been hastily removed. These occasional vapours, or mojete, are of the same quality as that permanent one in the Grotto del Cane, near the lake of Agnano, and which has been proved to consist chiefly of fixed air. The vapours which, in the volcanic language of Naples, are called fumaroli, are of another nature, and issue from spots all over the fresh and hot lavas while they are cooling; they are sulphureous, and so suffocating, that often the birds which are flying over them are overpowered, and fall down dead.

The interior of a volcano, that immense treasury of devastation, must undoubtedly be an object of philosophical curiosity: yet when we consider the nature of the attempt; that the incompact state of the materials, by affording no proper support, may hurry the incautious adventurer into the burning abyss; that the mephitic vapours may produce instantaneous suffocation; or that a sudden explosion may overwhelm him with destruction; we cannot wonder that so few have engaged in an exploit so replete with danger.

We should have remained ignorant of this state of this immense natural furnace, had not the spirit or temerity of eight Frenchmen, in the year 1801, enabled them successfully to explore this cavern of destruction. The mouth, or upper base, of the centre of Vesuvius, which is a little inclined to its axis, is represented by these travellers as 5720 feet in circumference. After walking round the aperture of the volcano, in order to chuse the most commodious part for descending, M. Dampiene, adjutant commandant, and M. Wickar, a painter, first descended without any accident at the determined point; when, however, they found themselves stopped by an excavation of 50 feet, which it was necessary to pass. Finding it impossible to obtain a fixed support on ashes so moveable, and being convinced that the friction of ropes would have destroyed both the point of support and the neighbouring masses, they resolved to return. Some stones at the same moment rolled from the summit, and occasioned a general agitation as they passed; the ground shook under their feet, and they had scarcely quitted it when it disappeared and fell in.

After walking once more round the mouth of the crater, they discovered at length a long declivity, smooth though steep, which appeared to conduct to the focus. When they had proceeded half-way, amidst a torrent of ashes which rolled down along with them, they found means to fix themselves on the edge of the precipice, twelve feet in height, which it was necessary to pass. With one of the lazaroni, however, they plunged down this precipice; and found themselves on the brink of another, which, however, not being quite so high, they passed with more ease. At length, amidst showers of falling lava, ashes, and stones, they reached the bottom of the crater.

They found the immense furnace still smoking in several places. The bottom of the crater, which from above appeared perfectly smooth, was found on the contrary, when they reached it, exceedingly rough and uneven. They passed over lava very porous, in general hard, but in some places, and particularly where they entered, still soft, so as even to yield under their feet. The spectacle, however, which most attracted them was the spiracles; which either at the bottom or interior sides, suffer the vapours to escape. These vapours, however, did not appear of a noxious quality. In traversing the crater they perceived a focus half-covered by a large mass of pumice stone, and which from its whole circumference emitted a strong heat. Reaumur's thermometer, on the summit of Vesuvius, stood at twelve degrees; in the crater it rose to sixteen; placed at one of the spiracles it indicated fifty-four, at another only twenty-two; and at the entrance of the focus it never rose higher than twenty-two degrees.

The volcanic productions in the crater were lava, exceedingly porous, and reduced by the fire in some places to scoriæ. It was of a dark-brown colour in general; and in some places reddish, with a very little white. The substances nearest the spiracles were covered or impregnated with sulphur, which sometimes was in a state of oxygenation. Some basaltic lava was also found, but in a small quantity. The burning focus produced the same results.

On the north side of the crater there were two large fissures, one of which was twenty feet in depth, the other fifteen. They were shaped like an inverted cone, and the matter with which they were covered was similar to the rest of the surface, but they emitted neither smoke nor heat.

The ascent of our adventurers was accomplished with more difficulty, though perhaps with less danger, than the descent. It also occupied a greater space of time; for they could only ascend one at a time after considerable intervals, for fear of burying, under torrents of dust and volcanic matters, those who immediately succeeded.

As the theory of volcanoes is by no means ascertained, we have thought it better to present our readers with facts than speculations, and the narrations which we have selected contain the most striking and best authenticated facts extant relative to these terrible phenomena. On these future philosophers may reflect, and possibly may elicit a more satisfactory explanation of them than any which has hitherto been presented to the public.

VOLKAMERIA, a genus of the didynamia angiospermia class of plants, the corolla whereof consists of a ringent, single petal: the tube is cylindric, and twice the length of the cup; the limb is divided into five plain segments; the fruit is a roundish bilocular capsule; the seed is a single bilocular nut. There are eight species.

VOLVOX, in zoology, a genus of animals belonging to the order of vermes infusoria. The body is round, simple, and pellucid. There are ten species, all of which live in water.

VOLUTA, in natural history, a genus of animals belonging to the class and order of vermes testacea. There are 144 species. The animals are of the slug kind; the shell is unilocular and spiral; the aperture narrow and without a beak; the columella plaited.

VOLUTE, a spiral scroll, used in the Ionic and composite capitals, whereof it makes the principal characteristic and ornament. See ARCHITECTURE.

VOMITING. See MEDICINE.

VORTEX, in the Cartesian philosophy, is a system or collection of particles of matter moving the same way, and round the same axis.

VORTICELLA, a genus of vermes infusoria. The generic character is, body contractile, naked, and furnished with ciliate rotatory organs. There are nearly sixty species of this genus. See Adams on the Microscope.

VOUCHER, a term of art, when the tenant in a writ of right calls another into the court who is bound to him to warranty, and that is either to defend the right against the demandant, or to yield him other lands, &c. in value, and extends to lands or tenements of freehold or inheritance. He that vouches is called voucher, and he that is vouched is called the vouchee. See RECOVERY.

VOWEL, in grammar, a letter which affords a complete sound in itself. In our language they are six in number.

The following views of the laxity with which the vowels are managed, and of their very great *convertibility*, in our language, have lately been given. Their different sounds are designated by the marks respectively used in these words:

Vowels:—án, àbly, ânt; béd, bè; ít, hìgh; ón, sò, ôff; ús, trùth, mūsic, fûll.

Diphthongs:—*oi*l; *ou*t.

Consonantal:—*w*it; *y*on.

UPUPA, in ornithology, a genus belonging to the order of picæ. The beak is arcuated, convex, and something blunt; the tongue is obtuse, triangular, entire, and very short; and the feet are fitted for walking. There are ten species, one of which, the epops, hoopoe, or dung-bird, is frequently seen in Britain. It may be readily distinguished from all others that visit this island by its beautiful crest, which it can erect or depress at pleasure. It is in length fifteen inches; the bill is black, two inches and a half long, slender, and incurvated; the irides are hazel: the crest consists of a double row of feathers, the highest about two inches long; the tips are black, their lower part of a pale orange colour: the neck is of a pale reddish brown, the breast and belly white; the lesser coverts of the wings are of a light brown; the back, scapulars, and wings, crossed with broad bars of white and black; the rump is white; the tail consists of only ten feathers, white marked with black, in form of a crescent, the horns pointing towards the end of the feathers. The legs are short and black; the exterior toe is closely united at the bottom to the middle toe. See Plate Nat. Hist. fig. 413.

According to Linnæus, it takes its name from its note, which has a sound similar to the word; or it may be derived from the French, huppé, or "crested:" it breeds in hollow trees, and lays two ash-coloured eggs: it feeds on insects, which it picks out of ordure of all kinds. Dr. Pallas affirms, that it breeds in preference in putrid carcases; and that he had seen the nest of one in the privy of an uninhabited house, in the suburbs of Tzaritsyn. Ovid says that Tereus was changed into this bird.

URANIA, a genus of the hexandria monogynia class and order of plants. There is no calyx; the corolla is two-petalled; nectarine two-leaved; capsule two-celled, many-seeded. There is one species.

URANIUM, a mineral found in Saxony, partly in a pure and partly in a mixed state. There are two varieties of these; the first of a blackish colour, quite opaque, tolerably hard, and with a specific gravity of about 7.5. The second is distinguished by a finer black colour, with here and there a reddish cast; by a stronger lustre, not unlike that of pitcoal; by an inferior hardness; and by a shade of green, which tinges its black colour when it is reduced to powder.

This fossil was called pechblende; and mineralogists, misled by the name, had taken it for an ore of zinc, till the celebrated Werner, convinced from its texture, hardness, and specific gravity, that it was not a blende, placed it among the ores of iron. Afterwards he suspected that it contained tungsten; and this conjecture was seemingly confirmed by the experiments of some German mineralogists, published in the Miners' Journal. But Klaproth, the most celebrated analyst in Europe, examined this ore in 1789, and found that it consists chiefly of sulphur combined with a peculiar metal, to which he gave the name of uranium.

Uranium is of a dark-grey colour; internally it is somewhat inclined to brown.

Its malleability is unknown. Its hardness is about 6. It requires a stronger heat for fusion than manganese. Indeed Klaproth only obtained it in very small conglutinated metallic grains, forming all together a porous and spongy mass. Its specific gravity is 6.440.

When exposed for some time to a red heat, it suffers no change. By means of nitric acid, however, it may be converted into a yellow powder. This is the peroxide or yellow oxide of uranium, which seems to be composed of about 56 parts of uranium and 44 of oxygen. This oxide is found native, mixed with the mineral above described. From the experiments of Proust, we learn that this metal is capable of forming only two oxides, but no description of the protoxide has been published; and the ore is so scarce that it is not every chemist who can gratify his curiosity by an examination of uranium.

Uranium is capable of combining with sulphur. The mineral from which Mr. Klaproth first obtained it is a native sulphuret of uranium.

URANOSCOPUS, star-gazer, a genus of fishes of the order jugulares. The generic character is, head large, depressed, rough; mouth furnished with an internal cirrus; gill-covers edged by a ciliated border; gill-membrane five-rayed.

Uranoscopus scaber, bearded star-gazer. The head of this fish is large, squarish, and covered by a strong bony case, roughened by an infinite number of small warts or protuberances: each side of this case is terminated above by two spines, the hindermost of which is the strongest, and covered by a skin: the under part has five spines, smaller than those above: the mouth, which is wide, opens in an almost vertical direction: the tongue is thick, short, and roughened with numerous small teeth: near the interior tip of the lower jaw is a membranaceous process which terminates in a long cirrus or beard extending to some distance beyond the lips, which are themselves edged with smaller ones: the eyes are situated very near each other on the top of the head: the body is of a somewhat squarish form as far as the vent, and thence becomes cylindric: it is covered with small scales, and marked near the back by a lateral line composed of small pores or points bending from the neck to the pectoral fins on each side, and thence in a straight line to the tail: on the back are two fins, of which the first is much shorter than the latter, and furnished with stronger spines: the pectoral fins are large, with soft rays: the ventral fins are small; the tail of moderate size, and rounded at the end. The colour of the body is brown, with a whitish or silvery cast towards the abdomen; the head, pectoral fins, and tail, having a strong ferruginous cast, and the first dorsal fin being marked towards its hind part by a large black spot.

The star-gazer is an inhabitant of the Mediterranean and northern seas, chiefly frequenting the shallow parts near the shores, where it lies concealed in the mud, with the tip of the head alone exposed: in this situation it waves the beards of the lips, and particularly the long cirrus of the mouth, in various directions, thus alluring the smaller fishes and marine insects which happen to be swimming near, and which mistaking these organs for worms, are instantly seized by their concealed enemy. The usual length of this fish is about twelve inches. It is in no esteem as an article of food, being generally considered as coarse and of an ill flavour: the gall was anciently considered as of peculiar efficacy in external disorders of the eyes. There are only two species, viz. the scaber and Japanicus.

UREA, the constituent and characteristic matter of urine, may be obtained by the following process: Evaporate by a gentle heat a quantity of human urine, voided six or eight hours after a meal, till it is reduced to the consistence of a thick syrup. In this state, when put by to cool, it concretes into a crystalline mass. Pour at different times upon this mass four times its weight of alcohol, and apply a gentle heat; a great part of the mass will be dissolved, and there will remain only a number of saline substances. Pour the alcohol solution into a retort, and distil by the heat of a sand-bath till the liquid, after boiling some time, is reduced to the consistence of a thick syrup. The whole of the alcohol is now separated, and what remains in the retort crystallizes as it cools. These crystals consist of the substance known by the name of urea.

Urea, obtained in this manner, has the form of crystalline plates crossing each other in different directions. Its colour is yellowish white: it has a fetid smell, somewhat resembling that of garlic or arsenic; its taste is strong and acrid, resembling that of ammoniacal salts; it is very viscid and difficult to cut, and has a good deal of resemblance to thick honey. When exposed to the open air, it very soon attracts moisture, and is converted into a thick brown liquid. It is extremely soluble in water; and during its solution a considerable degree of cold is produced. Alcohol dissolves it with facility, but scarcely in so large a proportion as water. The alcohol solution yields crystals much more readily on evaporation than the solution in water.

When nitric acid is dropt into a concentrated solution of urea in water, a great number of bright pearl-coloured crystals are deposited, composed of urea and nitric acid. No other acid produces this singular effect. The concentrated solution of urea in water is brown, but it becomes yellow when diluted with a large quantity of water. The infusion of nutgalls gives it a yellowish-brown colour; but causes no precipitate; neither does the infusion of tan produce any precipitate.

When heat is applied to urea, it very soon melts, swells up, and evaporates with an insupportably fetid odour. When distilled, there come over first benzoic acid, then carbonat of ammonia in crystals, some carbureted hydrogen gas, with traces of prussic acid and oil; and there remains behind a large residuum, composed of charcoal, muriat of ammonia, and muriat of soda. The distillation is accompanied with an almost insupportable fetid alliaceous odour. Two hundred and eighty parts of urea yield by distillation 200 parts of carbonat of ammonia, 10 parts of carbureted hydrogen gas, 7 parts of charcoal, and 68 parts of benzoic acid, muriat of soda, and muriat of ammonia. These three last ingredients Fourcroy and Vauquelin consider as foreign substances, separated from the urine by the alcohol at the same time with the urea. Hence it follows, that 100 parts of urea, when distilled, yield

92.027	carbonat of ammonia
4.608	carbureted hydrogen gas
3.225	charcoal
99.860	

Now 200 parts of carbonat of ammonia, according to Fourcroy and Vauquelin, are composed of 86 ammonia, 90 carbonic acid gas, and 24 water. Hence it follows that 100 parts of urea are composed of

39.5	oxygen
32.5	azote
14.7	carbon
13.3	hydrogen
100.0	

But it can scarcely be doubted that the water which was found in the carbonat of ammonia existed ready-formed in the urea before the distillation.

When the solution of urea in water is kept in a boiling heat, and new water is added as it evaporates, the urea is gradually decomposed, a very great quantity of carbonat of ammonia is disengaged, and at the same time acetic acid is formed, and some charcoal precipitates.

When a solution of urea in water is left to itself for some time, it is gradually decomposed. A froth collects on its surface; and air-bubbles are emitted which have a strong disagreeable smell, in which ammonia and acetic acid are distinguishable. The liquid contains a quantity of acetic acid. The decomposition is much more rapid if a little gelatine is added to the solution. In that case more ammonia is disengaged, and the proportion of acetic acid is not so great.

When the solution of urea is mixed with one-fourth of its weight of diluted sulphuric acid, no effervescence takes place; but, on the application of heat, a quantity of oil appears on the surface, which concretes upon cooling; the liquid which comes over into the receiver contains acetic acid, and a quantity of sulphat of ammonia remains in the retort dissolved in the undistilled mass. By repeated distillations, the whole of the urea is converted into acetic acid and ammonia.

When nitric acid is poured upon crystallized urea, a violent effervescence takes place, the mixture froths, assumes the form of a dark-red liquid, great quantities of nitrous gas, azotic gas, and carbonic acid gas, are disengaged. When the effervescence is over, there remains only a concrete white matter, with some drops of reddish liquid. When heat is applied to this residuum, it detonates like nitrat of ammonia. Into a solution of urea, formed by its attracting moisture from the atmosphere, an equal quantity of nitric acid, of the specific gravity 1.460, diluted with twice its weight of water, was added; a gentle effervescence ensued: a very small heat was applied, which supported the effervescence for two days. There was disengaged the first day a great quantity of azotic gas and carbonic acid gas; the second day, carbonic acid gas; and at last nitrous gas. At the same time with the nitrous gas the smell of the oxyprussic acid of Berthollet was perceptible. At the end of the second day, the matter in the retort, which was become thick, took fire, and burnt with a violent explosion. The residuum contained traces of prussic acid and ammonia. The receiver contained a yellowish acid liquor, on the surface of which some drops of oil swam.

Muriatic acid dissolves urea, but does not alter it. Oxymuriatic acid gas is absorbed very rapidly by a diluted solution of urea; small whitish flakes appear, which soon become brown, and adhere to the sides of the vessel like a concrete oil. After a considerable quantity of oxymuriatic acid had been absorbed, the solution, left to itself, continued to effervesce exceedingly slowly, and to emit carbonic acid and azotic gas. After this effervescence was over, the liquid contained muriat and carbonat of ammonia.

Urea is dissolved very rapidly by a solution of potass or soda, and at the same time a quantity of ammonia is disengaged; the same substance is disengaged when urea is treated with barytes, lime, or even magnesia. Hence it is evident, that this appearance must be ascribed to the muriat of ammonia, with which it is constantly mixed. When pure solid potass is triturated with urea, heat is produced, a great quantity of ammonia is disengaged, the mixture becomes brown, and a substance is deposited, having the appearance of an empyreumatic oil. One part of urea and two of potass, dissolved in four times its weight of water, when distilled, gives out a great quantity of ammoniacal water; the residuum contains acetat and carbonat of potass.

When muriat of soda is dissolved in a solution of urea in water, it is obtained by evaporation, not in cubic crystals, its usual form, but in regular octahedrons. Muriat of ammonia, on the contrary, which crystallizes naturally in octahedrons, is converted into cubes by dissolving and crystallizing it in the solution of urea.

URENA, a genus of the monadelphia polyandria class of plants, the corolla whereof consists of five oblong, obtuse, connated petals, broader than the apex, and narrower at the base; the fruit is a round echinated capsule, with five angles, consisting of five cells, and made up of five valves; the seeds are solitary, roundish, and compressed. There are eight species.

URETERS. See ANATOMY.

URETHRA. See ANATOMY.

URIC ACID. Uric or lithic acid was discovered by Scheele in 1776. It is the most common constituent of urinary calculi, and exists also in human urine. That species of calculus which resembles wood in its colour and appearance is composed entirely of this substance. It was called at first lithic acid; but this name, in consequence of the remarks made by Dr. Pearson on its impropriety, has been laid aside, and that of uric acid substituted in its place.

Uric acid in this state has a brown colour; it is hard, and crystallized in small scales. It has neither taste nor smell, is insoluble in cold water, but soluble in 360 parts of boiling water. The solution reddens vegetable blues, especially the tincture of turnsol. A great part of the acid precipitates again as the water cools. It combines readily with alkalies and earths; but the compound is decomposed by every other acid. Muriatic acid has no action on it, neither has sulphuric acid while cold, but when assisted by heat it decomposes it entirely.

When triturated with potass or soda, it forms a saponaceous paste, very soluble in water when there is an excess of alkali, but sparingly when the alkali is neutralized. The urat of potass or of soda is nearly tasteless. The last is found crystallized, constituting gouty concretions. Ammonia does not dissolve uric acid, but it combines with it, and forms a salt not more soluble than the pure acid, and resembling it in its external characters. Neither does uric acid dissolve in lime-water; the alkaline carbonats have no action whatever on it.

Nitric acid dissolves it readily; the solution is of a pink-colour, and has the property of tinging animal substances, the skin for instance, of the same colour. When this solution is boiled, a quantity of azotic gas, carbonic acid gas, and of prussic acid, is disengaged. When oxymuriatic acid gas is made to pass into water containing this acid suspended in it, the acid assumes a gelatinous appearance, then dissolves; carbonic acid gas is emitted, and the solution yields by evaporation muriat of ammonia, superoxalat of ammonia, muriatic acid, and malic acid.

When uric acid is distilled, about a fourth of the acid passes over a little altered, and is found in the receiver crystallized in plates; a few drops of thick oil make their appearance; $\frac{1}{8}$th of the acid of concrete carbonat of ammonia, some prussiat of ammonia, some water, and carbonic acid, pass over; and there remains in the retort charcoal, amounting to about $\frac{1}{80}$th of the weight of the acid distilled.

These facts are sufficient to shew us that uric acid is composed of carbon, azote, hydrogen, and oxygen; and that the proportion of the two last ingredients is much smaller than of the other two.

URINE. No animal substance has attracted more attention than this, both on account of its supposed connection with various diseases, and on account of the singular products obtained from it. In general, healthy urine is a transparent liquid of a light amber-colour, an aromatic smell, and a disagreeable bitter taste. Its specific gravity varies, according to Mr. Cruikshank, from 1.005 to 1.033. When it cools, the aromatic smell leaves it, and is succeeded by another, well known by the name of urinous smell. This smell is succeeded in two or three days by another, which has a considerable resemblance to that of sour milk. This smell gradually disappears in its turn, and is succeeded by a fetid alkaline odour.

Urine reddens paper stained with turnsole and with the juice of radishes, and therefore contains an acid.

If a solution of ammonia is poured into fresh urine, a white powder precipitates, which has the properties of phosphat of lime. The presence of this substance in urine was first discovered by Scheele. If lime-water is poured into urine, phosphat of lime precipitates in greater abundance than when ammonia is used; consequently urine contains phosphoric acid. Thus we see that the phosphat of lime is kept dissolved in urine by an excess of acid, or it is in the state of super-phosphat. This also was first discovered by Scheele. This substance is most abundant in the urine of the sick. Berthollet has observed, that the urine of gouty people is less acid than that of people in perfect health. The average quantity of phosphat of lime in healthy urine is, as Cruikshank has ascertained, about $\frac{1}{900}$ of the weight of the urine.

If the phosphat of lime precipitated from urine is examined, a little magnesia will be found mixed with it. Fourcroy and Vauquelin have ascertained that this is owing to a little phosphat of magnesia which urine contains, and which is decomposed by the alkali or lime employed to precipitate the phosphat of lime.

Proust informs us that carbonic acid exists in urine, and that its separation occasions the froth which appears during the evaporation of urine. Fourcroy and Vauquelin, on the other hand, consider this acid as formed during the evaporation, by the decomposition of the urea. The observations of Proust confirm those which had been made by Priestley and Percival.

Proust has observed, that urine kept in new casks deposits small crystals which effloresce in the air and fall to powder. These crystals possess the properties of carbonat of lime. Hence we must conclude that urine contains carbonat of lime; a very extraordinary fact, if we reflect that super-phosphat of lime is also present.

When fresh urine cools, it often lets fall a brick-coloured precipitate, which Scheele first ascertained to be crystals of uric acid. All urine contains this acid, even when no sensible precipitate appears when it cools. For if a sufficient quantity of clear and fresh urine is evaporated to $\frac{1}{178}$ of its weight, a subtle powder precipitates to the bottom, and attaches itself in part very firmly to the vessel. This part may be dissolved in pure alkali, and precipitated again by acetic acid. It exhibits all the properties of uric acid. The fact is, that the precipitate which usually falls when urine cools consists chiefly of phosphat of lime and uric acid. It may be dissolved in diluted nitric acid. If the solution is heated and evaporated to dryness, it assumes a fine rose-colour if uric acid is present. The proportion of uric acid varies considerably in urine. It crystallizes in small red prisms, partly on the surface, if urine is mixed with some nitric acid, and left exposed to the air.

During intermittent fevers, and especially during diseases of the liver, a copious sediment of a brick-red colour is deposited from urine. This sediment is the rosacic acid of Proust. Scheele considered this sediment as uric acid mixed with some phosphat of lime; and the same opinion has been entertained by other chemists: but Proust affirms that it consists chiefly of a different substance, to which he has given the name of rosacic acid from its colour, mixed with a certain proportion of uric acid and phosphat of lime. This rosacic acid, he informs us, is distinguished from the uric by the facility with which it dissolves in hot water, the violet precipitate which it occasions in muriat of gold, and by the little tendency which it has to crystallize.

If fresh urine is evaporated to the consistence of a syrup, and muriatic acid is then poured into it, a precipitate appears which possesses the properties of benzoic acid. Scheele first discovered the presence of benzoic acid in urine. He evaporated it to dryness, separated the saline part, and applied heat to the residuum. The benzoic acid was sublimed, and found crystallized in the receiver. Considerable quantities of benzoic acid may thus be obtained from the urine of horses and cows, where it is much more abundant than in human urine. In human urine it varies from $\frac{1}{1000}$ to $\frac{1}{10000}$ of the whole. Proust affirms that the acid obtained by Scheele's process is not the benzoic, but another possessed of similar properties; but differing in this circumstance, that nitric acid decomposes it, whereas it only whitens benzoic acid.

When an infusion of tan is dropt into urine, a white precipitate appears, having the properties of the combination of tan and albumen, or gelatine. Urine, therefore, contains albumen or gelatine. These substances had been suspected to be in urine, but their presence vas first demonstrated by Seguin, who discovered the above method of detecting them. Their quantity in healthy urine is very small. Cruikshank found that the precipitate afforded by tan in healthy urine amounted to $\frac{1}{240}$th part of the weight of the urine. It is to these substances that the appearance of the cloud, as it is called, or the mucilaginous matter, which is sometimes deposited as the urine cools, is owing. It is probable that healthy urine contains only gelatine, and not albumen, though the quantity is too small to admit of accurate examination; but in many diseases the quantity of these matters is very much increased. The urine of dropsical people often contains so much albumen, that it coagulates not only on the addition of acids, but even on the application of heat. In all cases of impaired digestion, the albuminous and gelatinous part of urine is much increased. This forms one of the most conspicuous and important distinctions between the urine of those who enjoy good and bad health.

If urine is evaporated by a slow fire to the consistence of a thick syrup, it assumes a deep brown colour, and exhales a fetid ammoniacal odour. When allowed to cool, it concretes into a mass of crystals, composed of all the component parts of urine. If four times its weight of alcohol is poured upon this mass at intervals, and a slight heat applied, the greatest part of it is dissolved. The alcohol, which has acquired a brown colour, is to be decanted off, and distilled in a retort in a sand-heat, till the mixture has boiled for some time, and acquired the consistence of a syrup. By this time the whole of the alcohol has passed off; and the matter, on cooling, crystallizes in quadrangular plates which intersect each other. This substance is urea, which composes $\frac{19}{20}$ of the urine, provided the watery part is excluded. To this substance the taste and smell of urine are owing. It is a substance which characterizes urine, and constitutes it what it is, and to which the greater part of the very singular phenomena of urine is to be ascribed. (See UREA.)

It may be detected by evaporating urine to the consistence of a syrup, and pouring into concentrated nitric acid. Immediately a great number of white shining crystals appear in the form of plates very much resembling crystallized boracic acid. These chrystals are urea combined with nitric acid.

The quantity of urea varies exceedingly in different urines. In the urine voided soon after a meal, very little of it is to be found, and scarcely any at all in that which hysterical patients void during a paroxysm.

According to Fourcroy and Vauquelin, the colour of urine depends upon the urea: the greater the proportion of urea, the deeper the colour. But Proust has detected a resinous matter in urine similar to the resin of bile; and to this substance he ascribes the colour of urine. If urine, evaporated to the consistence of an extract, is mixed with sulphuric acid and distilled, this resin, he informs us, separates during the distillation. What is first obtained is soft, but the last portions are in the state of a dry powder. The consistence and colour of this resin resemble castor: it is very soluble in alcohol, and precipitated from its solution by water: but it is also soluble in water; and, according to Proust, is the resin of bile, somewhat modified by its passage through the urinary organs.

If urine is slowly evaporated to the consistence of a syrup, a number of crystals make their appearance on its surface: these possess the properties of muriat of soda. Urine therefore contains muriat of soda. It is well known that muriat of soda crystallizes in cubes; but when obtained from urine it has the form of octahedrons. This singular modification of its form is owing to the action of urea. It has been long known that urine saturated with muriat of soda deposits that salt in regular octahedrons.

The saline residuum which remains after the separation of urea from crystallized urine by means of alcohol has been long known under the names of fusible salt of urine and microcosmic salt. Various methods of obtaining it have been given by chemists; from Boerhaave, who first published a process, to Rouelle and Chaulnes, who gave the method just mentioned. If the saline mass is dissolved in a sufficient quantity of hot water, and allowed to crystallize spontaneously in a close vessel, two sets of crystals are gradually deposited. The lowermost set has the figure of flat rhomboidal prisms; the uppermost, on the contrary, has the form of rectangular tables. These two may be easily separated by exposing them for some time to a dry atmosphere. The rectangular tables effloresce and fall to powder, but the rhomboidal prisms remain unaltered.

When these salts are examined, they are found to have the properties of phosphats. The rhomboidal prisms consist of phosphat of ammonia united to a little phosphat of soda; the rectangular tables, on the contrary, are phosphat of soda united to a small quantity of phosphat of ammonia. Urine, then, contains phosphat of soda and phosphat of ammonia.

When urine is cautiously evaporated, a few cubic crystals are often deposited among the other salts; these crystals have the properties of muriat of ammonia. Now the usual form of the crystals of muriat of ammonia is the octahedron. The change of its form in urine is produced also by urea. This salt is obtained in greater abundance when the crystals of urea obtained from the alcohol solution are distilled.

When urine is boiled in a silver bason it blackens the bason; and if the quantity of urine is large, small crusts of sulphuret of silver may be detached. Hence we see that urine contains sulphur. This sulphur exhales along with the carbonic acid when the urine putrefies; for the fumes which separate from urine in that state blacken paper stained with acetat of lead.

Urine, then, contains the following substances:

1. Water,
2. Phosphoric acid,
3. Phosphat of lime,
4. Phosphat of magnesia,
5. Carbonic acid,
6. Carbonat of lime,
7. Uric acid,
8. Rosacic acid,
9. Benzoic acid,
10. Gelatine and albumen,
11. Urea,
12. Resin,
13. Muriat of soda,
14. Phosphat of soda,
15. Phosphat of ammonia,
16. Muriat of ammonia,
17. Sulphur.

These are the only substances which are constantly found in healthy urine; but it contains also occasionally other substances. Very often muriat of potass may be distinguished among the crystals which form during its evaporation. The presence of this salt may always be detected by dropping cautiously some tartaric acid into urine. If it contains muriat of potass, there will precipitate a little tartar, which may easily be recognized by its properties.

Urine sometimes also contains sulphat of soda, and even sulphat of lime. The presence of these salts may be ascertained by pouring into urine a solution of muriat of barytes; a copious white precipitate appears, consisting of the barytes combined with phosphoric acid, and with sulphuric acid if any is present. This precipitate must be treated with a sufficient quantity of muriatic acid. The phosphat of barytes is dissolved, but the sulphat of barytes remains unaltered,

No substance putrefies sooner, or exhales a more detestable odour during its spontaneous decomposition, than urine; but there is a very great difference in this respect in different urines. In some, putrefaction takes place almost instantaneously as soon as it is voided; in others, scarcely any change appears for a number of days. Fourcroy and Vauquelin have ascertained that this difference depends on the quantity of gelatine and albumen which urine contains. When there is very little of these substances present, urine remains long unchanged; on the contrary, the greater the quantity of gelatine or albumen, the sooner does putrefaction commence. The putrefaction of urine, therefore, is in some degree the test of the health of the person who has voided it: for a superabundance of gelatine in urine always indicates some defect in the power of digestion.

The rapid putrefaction of urine, then, is owing to the action of gelatine on urea. We have seen already the facility with which that singular substance is decomposed; and that the new products into which it is changed are, ammonia, carbonic acid, and acetic acid. Accordingly, the putrefaction of urine is announced by an ammoniacal smell. Mucilaginous flakes are deposited, consisting of part of the gelatinous matter. The phosphoric acid is saturated with ammonia; and the phosphat of lime, in consequence, is precipitated. Ammonia combines with the phosphat of magnesia; and forms with it a triple salt, which crystallizes upon the sides of the vessel in the form of white crystals, composed of six-sided prisms, terminated by six-sided pyramids. The uric and benzoic acids are saturated with ammonia; the acetic acid, and the carbonic acid, which are the products of the decomposition of the urea, are also saturated with ammonia; and notwithstanding the quantity which exhales, the production of this substance is so abundant, that there is a quantity of unsaturated alkali in the liquid. Putrefied urine, therefore, contains chiefly the following substances, most of which are the products of putrefaction:

Ammonia,
Carbonat of ammonia,
Phosphat of ammonia,
Phosphat of magnesia and ammonia,
Urat of ammonia,
Acetat of ammonia,
Benzoat of ammonia,
Muriat of soda,
Muriat of ammonia;

besides the precipitated gelatine, and phosphat of lime.

The distillation of urine produces almost the same changes: for the heat of boiling water is sufficient to decompose urea, and to convert it into ammonia, carbonic, and acetic acids. Accordingly, when urine is distilled, there come over water, containing ammonia dissolved in it, and carbonat of ammonia in crystals; the acids contained in urine are saturated with ammonia, and the gelatine and phosphat of lime precipitate.

Such are the properties of human urine in a state of health: but this excretion is singularly modified by disease; and the changes to which it is liable have attracted the attention of physicians in all ages, because they serve in some measure to indicate the state of the patient and the progress of the disease under which he labours. The following are the most remarkable of these changes that have been observed:

1. In inflammatory diseases the urine is of a red colour, and peculiarly acrid; it deposits no sediment on standing, but with oxymuriat of mercury it yields a copious precipitate.

2. During jaundice the urine has an orange-yellow colour, and communicates the same tint to linen. Muriatic acid renders this urine green, and thus detects the presence of a little bile.

3. About the end of inflammatory diseases the urine becomes abundant, and deposits a copious pink-coloured sediment, composed of rosacic acid, a little phosphat of lime, and uric acid.

4. During hysterical paroxysms, the urine usually flows abundantly. It is limpid and colourless, containing much salt, but scarcely any urea or gelatine.

5. Mr. Berthollet observed that the urine of gouty persons contains usually much less phosphoric acid than healthy urine. But during a gouty paroxysm it contains much more phosphoric acid than usual; though not more than constantly exists in healthy urine.

6. In general dropsy, the urine is loaded with albumen, and becomes milky, or even coagulates, when heated, or at least when acids are mixed with it. In dropsy from diseased liver, no albumen is present, the urine is scanty, high-coloured, and deposits the pink-coloured sediment.

7. In dyspepsia, the urine always yields a copious precipitate with tan, and putrefies rapidly.

8. The urine of rickety patients is said to be loaded with phosphat of lime, or, according to others, with oxalat of lime.

9. In diabetes, the urine is sweet-tasted and often loaded with saccharine matter. In one case, the urine emitted daily by a diabetic patient, according to the experiments of Cruikshank, contained 29 ounces of sugar.

The urine of other animals differs considerably from that of man. For the analyses of the urine of quadrupeds hitherto made, we are chiefly indebted to Rouelle junior. The following facts have been ascertained by that chemist, and by the late experiments of Fourcroy and Vauquelin:

I. The urine of the horse has a peculiar odour: after exercise it is emitted thick and milky; at other times it is transparent, but becomes muddy soon after its emission. When exposed to the air, its surface becomes covered with a crust of carbonat of lime. It gives a green colour to syrup of violets, and has the consistence of mucilage. The following are its constituents as estimated by Fourcroy and Vauquelin from their experiments:

Carbonat of lime	0.011
Carbonat of soda	0.009
Benzoat of soda	0.024
Muriat of potass	0.009
Urea	0.007
Water and mucilage	0.940
	1.000

From the late experiments of Mr. Giese, we learn that the quantity of benzoat of soda varies considerably in the urine of horses. In some specimens he found it in abundance, and easily precipitated by muriatic acid. In others there was little or none. He could detect no benzoic acid in the food of horses. Hence he considers it as formed within the animal, and he thinks that it appears only in cases of disease.

II. The urine of the cow has a strong resemblance to that of the horse; it has nearly the same odour, and the same mucilaginous consistence It tinges syrup of violets green, and deposits a gelatinous matter. On standing, small crystals are formed on its surface. It contains, according to Rouelle,

1. Carbonat of potass,
2. Sulphat of potass,
3. Muriat of Potass,
4. Benzoic acid,
5. Urea.

III. The urine of the camel was also examined by Rouelle. Its odour resembles that of the urine of the cow; its colour is that of beer; it is not mucilaginous, and does not deposit carbonat of lime. It gives a green colour to syrup of violets, and effervesces with acids like the urine of the horse and cow. Rouelle obtained from it,

1. Carbonat of potass,
2. Sulphat of potass,
3. Muriat of potass,
4. Urea.

IV. The urine of the rabbit has been lately analysed by Vauquelin. When exposed to the air, it becomes milky, and deposits carbonat of lime. It gives a green colour to syrup of violets, and effervesces with acids. That chemist detected in it the following substances:

1. Carbonat of lime,
2. Carbonat of magnesia,
3. Carbonat of potass,
4. Sulphat of potass,
5. Sulphat of lime,
6. Muriat of potass,
7. Urea,
8. Gelatine,
9. Sulphur.

V. Vauquelin has also made some experiments on the urine of the guinea-pig, from which it appears that it resembles the urine of the other quadrupeds. It deposits carbonat of lime, gives a green colour to syrup of violets, and contains carbonat and muriat of potass, but no phosphat nor uric acid.

Thus it appears that the urine of the graminivorous quadrupeds agrees with the human in containing urea, but differs from it materially in being destitute of phosphoric acid, phosphats, and uric acid. Whether the urine of carnivorous quadrupeds contains these last substances has not been ascertained, but it is probable that it does.

URSA, the *bear*, in astronomy, a name common to two constellations of the northern hemisphere, near the pole, distinguished by major and minor. The ursa major, or the great bear, according to Ptolemy's catalogue, consists of thirty-five stars: according to Tycho's, of fifty-six: but in the Britannic catalogue we have two hundred and fifteen.

The ursa minor, or little bear called also Charles's wain, and by the Greeks cynosura, by its neighbourhood to the north pole, gives the denomination αρκτος, bear, thereto. Ptolemy and Tycho make it to consist of eight stars, but Flamsteed of fourteen.

URSUS, *bear*, a genus of quadrupeds of the order feræ: the generic character is, front teeth six both above and below: the two lateral ones of the lower jaw longer than the rest and lobed; with smaller or secondary teeth at their internal bases; canine teeth solitary; grinders five or six on each side, the first approximated to the canine teeth; tongue smooth; snout prominent; eyes furnished with a nictitating membrane. There are ten species.

1. Ursus arctos. The common bear, with some variation as to size and colour, is a native of almost all the northern parts of Europe and Asia, and is even said to be found in some of the Indian islands, as Ceylon, &c. It inhabits woods and unfrequented places, and feeds chiefly on roots, fruits, and other vegetable substances, but occasionally preys on animals. In the Alpine regions the bear is brown; in some other parts of Europe, black; and in some parts of Norway has been seen of a grey colour, and even perfectly white: this latter change of colour sometimes takes place, as is well known, in several other animals, and most frequently in such as are naturally black or of very dark colours. The brown, the black, the grey, and the white land bears are, therefore, to be considered as of the same species: yet it is observed that the brown and black varieties differ somewhat in their manner of life; the black confining itself almost entirely to vegetable food; the brown, on the contrary, frequently attacking and preying upon other animals, and destroying lambs, kids, and even sometimes cattle, and sucking the blood in the manner of the cat and weasel tribes. Linnæus adds, that the bear has a way of blowing up his prey, and of hiding or burying a part of it. Bears are reported to be particularly fond of honey, in search of which they will climb trees, in order to get at the nests of wild bees; for the bear, notwithstanding his awkward form, is expert in climbing, and sometimes takes up his residence in the hollow of a very large tree. The bear will also catch and devour fish, occasionally frequenting the banks of rivers for that purpose.

The bear passes a considerable part of the winter in a state of repose and abstinence; emerging only at distant intervals from his den, and again concealing himself in his retreat till the approach of the vernal season. The females are said to continue in this state much longer than the males, and it is during this period that they bring forth their young, which are commonly two in number. These the antients imagined to be nearly shapeless masses, gradually licked and fashioned into regular form by the parent; an opinion now sufficiently exploded. The young, however, though not shapeless, have a different aspect from the grown animal; the snout being much sharper, and their colour yellowish: they are said to be blind for nearly the space of a month.

2. Ursus Americanus, American bear. This, which is now considered as a distinct species, and not to be confounded with the black bear of Europe, has a long, pointed nose, and narrow forehead: the cheeks and throat of a yellowish-brown colour; the hair on the whole body and limbs of a glossy black, smoother and shorter than that of the European kind. It is also said to be, in general, smaller than the European bear, though instances have been known in which its size, at least, equalled the European, since Mr. Bartram assures us, that a bear was killed in Florida which weighed four hundred pounds.

This animal inhabits all the northern parts of America, migrating occasionally from the northern to the more southerly parts in quest of food, which is said to be entirely vegetable; and it is even affirmed, that, when pressed by extreme want, they will still neglect all animal food whenever they can obtain a supply of roots and grain. They, however, sometimes destroy fish, and particularly herrings, when these fish happen to come up into the creeks in shoals. They are said to continue in their winter retreats, either in dens beneath the snow under ground, or in the hollows of old trees, for the space of five or six weeks without food.

3. Ursus maritimus, polar bear. This is a far larger species than the common bear, and is said to have been sometimes found of the length of twelve feet. The head and neck are of a more lengthened form than in the common bear, and the body itself is longer in proportion. The whole animal is white, except the tip of the nose and the claws, which are jet-black: the ears are small and rounded; the eyes small; the teeth of extraordinary magnitude: the hair is of a great length, and the limbs are extremely large and strong. See Plate Nat. Hist. fig. 415. It seems confined to the very coldest parts of the globe; being found within 80 degrees of north latitude, as far as any navigators have yet penetrated. The shores of Hudson's-bay, Greenland, and Spitsbergen, are its principal places of residence; but it is said to have been accidentally carried on floating ice as far south as Newfoundland. This species seems to have been often confounded by authors with the white variety of the common bear, which is occasionally found in the northern regions.

The polar bear is an animal of tremendous strength and fierceness. Barentz, in his voyage in search of a north-east passage to China, had proofs of the ferocity of these animals, in the island of Nova Zembla, where they attacked his seamen, seizing them in their mouths, carrying them off with the utmost ease, and devouring them in the sight of their comrades. It is said that they will attack and attempt to board armed vessels, at a great distance from shore; and have sometimes been with much difficulty repelled. Their usual food consists of seals, fish, and the carcases of whales; but, when on land, they prey on deer, and other animals, as hares, young birds, &c. they also eat various kinds of berries which they happen to find. They are said to be frequently seen in Greenland in great droves, allured by the scent of the flesh of seals: and will sometimes surround the habitations of the natives, and attempt to break in; and it is added, that the most successful method of repelling them is by the smell of burnt feathers. They grow extremely fat, a hundred pounds of fat having been taken from a single beast. The flesh is said to be coarse, but the skin is valued for coverings of various kinds, and the Greenlanders often wear it as a clothing. The split tendons are said to form an excellent thread. During the summer they reside chiefly on the ice-islands, and pass frequently from one to another; being extremely expert swimmers. They have been seen on these ice-islands at the distance of more than eighty miles from land, preying and feeding as they float along. They lodge in dens, formed in the vast masses of ice, which are piled in a stupendous manner, leaving great caverns beneath: here they breed, and bring one or two young at a time, and sometimes, but very rarely, three. The affection between parent and young is so great, that they will sooner die than desert each other. They follow their dams a very long time, and grow to a large size before they quit them.

During winter they retire, and bed themselves deep beneath the snow, or else beneath the fixed ice of some eminence, where they pass in a state of torpidity the long and dismal arctic night, appearing only with the return of the sun.

The skins of the polar bear, says Mr. Pennant, were formerly offered by the hunters in the arctic regions to the high altars of cathedrals and other churches, for the priest to stand on during the celebration of mass in winter.

4. Ursus gulo, glutton. This animal is a native of the most northern parts of Europe and Asia, occurring in Sweden, Norway, Lapland, and Siberia, as well as in some of the Alpine regions, and in the forests of Poland and Courland. It is also found in the northern parts of America, being not uncommon about Hudson's-bay.

The glutton is considerably larger than a badger, measuring about a yard from nose to tail, and the tail about a foot; but it seems to vary in size, and is often less than this. The muzzle, as far as beyond the eyes, is blackish brown, and covered with hard shining hair: over the forehead, down the sides of the head, between the eyes and ears, runs a whitish or ash-coloured band or fillet: the top of the head and whole length of the back are black-brown, the colour widening somewhat over the sides as it passes on, and again lessening or contracting towards the tail. In the American variety a whitish or ash-coloured band or border runs along the body, in the same manner as the ferruginous one in the European kind.

The glutton, as its name imports, has the character of a very voracious animal, preying indiscriminately both on fresh prey and carrion. One of which was kept at Dresden would eat thirteen pounds of flesh in a day, without being satisfied. It attacks deer, birds, field-mice, &c. and even sometimes the larger cattle; and it is said to sit on the branches of trees, and suddenly to spring down on such animals as happen to pass beneath; tearing them, and sucking the blood, till they fall down through faintness, when it begins to devour the spoil. In winter it seeks out and catches ptarmigans under the snow. What it cannot devour at once, it is said to hide under ground, or in the cavity of some tree. It is said to be an animal of uncommon fierceness and strength; and will sometimes dispute the prey both with the wolf and bear. It is also extremely fetid. It breeds once a year, and brings from two to four young at a litter. The fur is much used for muffs, linings, &c. Those skins are said to be preferred which have least of the ferruginous tinge, and for this reason the Siberian variety, which is blacker than the rest, is most esteemed. The ursus luscus, or wolverene, appears to be a variety of this animal.

5. Ursus lotor, the raccoon, is a native of the new world, and is principally an inhabitant of the northern parts of that continent. It is also found in some of the West Indian islands. Its colour is grey; the face white; the eyes each imbedded in a large patch of black, which forms a kind of band across the forehead, and is crossed by a dusky stripe running down the nose. The visage is shaped like that of a fox, the forehead being broad and the snout sharp; the eyes are large and greenish: the ears short and slightly rounded; and the upper jaw is longer than the lower: the tail, which is covered with bushy hair, tapers to the end, and is annulated with several black bars: the body is broad, the back arched, the limbs rather short, and the fore legs shorter than the hinder; the animal is covered with thick and long hair, which has a somewhat upright growth: the feet are dusky, and have five toes with very sharp claws. The colour of the raccoon is generally a dark grey. The length of the animal is two feet from nose to tail, and the tail about one foot. See Plate Nat. Hist. fig. 414. The food of the raccoon, in its wild state, consists chiefly of maize, which it eats while the ears are tender, as well as sugar-canes, various sorts of fruit, as apples, chesnuts, &c. It is also supposed to devour birds and their eggs, and is, therefore, considered as an enemy to poultry. It chiefly feeds by night, and by day keeps in its hole, except in dull weather. In winter, and in very bad weather, it keeps altogether within, and is popularly believed to live like the bear, by sucking its paws. The raccoon, however, is an active and sprightly animal when taken into a state of domestication. It has a kind of oblique gait in walking, can leap and climb with great ease, and is very frequently seen on trees. It is easily tamed, and is frequently kept in houses by the Americans, and will live on bread, milk, fish, eggs, &c. It is particularly delighted with sweets of every kind, and has as great a dislike to acids. In eating, it commonly sits on its hind legs, and uses its fore feet in the manner of hands. It has a way of dipping

all manner of dry food that is given it into water before it eats it; as well as of rolling it between its paws for some time. When it kills birds, it proceeds exactly in the manner of a polecat; first biting off the head, and then sucking out the blood. It drinks but little, and is a very cleanly animal. It is extremely expert in opening oysters, on which, as well as on crabs and various other kinds of shell-fish, it frequently feeds in its wild state. It is, when tamed, extremely active and playful: but is of a capricious disposition, and not easily reconciled when offended. When angry, its voice is like a hoarse bark, and at other times soft and sharp. In its wild state it generally inhabits the hollows of trees; but in a domestic state shews no particular inclination for warmth; nor is it observed to be desirous of lying on straw, or any other substance, in preference to the bare ground. It sleeps from about midnight to noon, at which time it comes out for food and exercise. According to Linnæus, the raccoon has a wonderful antipathy to hogs' bristles, and is much disturbed at the sight of a brush. It produces from two to three young at a birth: this commonly takes place in the month of May. The fur of the raccoon is used by the hatters, and is considered as next in merit for this purpose to that of the beaver.

6. Ursus meles, the badger, is an inhabitant of all the temperate parts of Europe and Asia. Its usual length is about two feet from the nose to the tail, which measures six inches. It is an animal of very clumsy make, being thick-necked and thick-bodied, with very short legs. It commonly resides in a hole or den under ground, out of which it emerges by night in quest of food; feeding chiefly on roots and fruits; but it will also devour frogs, worms, &c. The badger is of an uniform grey colour on the upper parts; and the throat, breast, belly, and legs, are black: the face is white, and along each side of the head runs a long and somewhat triangular or pyramidal band of black, including the eyes and ears: the eyes are small, and the ears short and rounded: the claws on the fore feet are very long and straight, and it is principally from this circumstance that Mr. Pennant ranks it under a separate genus, instead of including it under that of ursus, or bear. Authors have sometimes made a distinction between what they call the sow badger and the dog badger; but this is supposed to be perfectly untenable, and if there is any perceptible variation, is probably no other than a mere sexual difference. The hair of the badger, both on the body, limbs, and tail, is very thick; and the teeth, legs, and claws, are very strong; so that he makes a very vigorous defence when attacked. When taken young, the badger may be easily tamed, and generally prefers raw flesh to every other food in a state of captivity. It is a very cleanly animal, and is observed to keep its subterraneous mansion extremely neat. The female produces about three or four young: this happens in summer; and, according to the count de Buffon, the parent seizes on young rabbits, which she drags out of their burrows, birds, eggs, snakes, and many other animals, in order to feed her young. Like the bear, this animal is also fond of honey, and will attack hives in order to obtain it. The badger sleeps a great deal, especially during winter, when he imitates the practice of the bear, confining himself to his den in a state of semi-torpidity.

7. Ursus labradorius, American badger. In its general appearance this extremely resembles the common badger, and might almost pass for a variety only: it is, however, somewhat smaller, and the black bands on the face are much narrower and do not include the eyes, but commence behind them, and run along the top of the neck: the ears are surrounded with black: the upper parts of the body are nearly of the same colour as in the common badger, but rather paler, and with a slight yellowish cast; and the breast and belly are of a light ash-colour, instead of black: the legs are of a dusky brown: the claws are at least as long and strong as in the European badger, if not more so. This species is rather scarce in America. It is found in the neighbourhood of Hudson's-bay, and in Terra di Librador, and as Mr. Pennant suspects, as low as Pennsylvania, where it is called the ground-hog.

URTICA, a genus of plants of the class monœcia, and order tetrandria; and in the natural system classed under the 53d order, scabridæ. The male flower has a calyx of four leaves; no corolla; a nectarium minute, central, urn-fashioned. The female a bivalve calyx; and a single, oval, glossy seed. There are 59 species, three of which are British plants: 1. The pilulifera, Roman nettle, has a stalk branched, two or three feet high. Leaves opposite, oval, serrated, stinging. Fruit globose. 2. The urens, less stinging nettle, has a stem a foot high. Leaves roundish, deeply serrated, opposite. The stings are very curious microscopic objects: they consist of an exceedingly fine-pointed, tapering, hollow substance, with a perforation at the point, and a bag at the base. When the spring is pressed upon, it readily perforates the skin, and at the same time forces up some of the acrimonious liquor contained in the bag into the wound. 3. The dioica, common nettle, has a square firm stem, three or four feet high. Leaves heart-shaped, long-pointed, serrated, beset with stings. Flowers in long catkins. The aculei, or stings of the nettle, have a small bladder at their base full of a burning corrosive liquor: when touched, they excite a blister, attended with a violent itching pain, though the sting does not appear to be tubular, or perforated at the top, nor any visible liquor to be infused into the puncture made by it in the flesh. It seems certain, however, that some of this liquor is insinuated into the wound, though invisibly, since the stings of the dried plant excite no pain.

Nettle-tops in the spring are often boiled and eaten by the common people instead of cabbage-greens. In Arran, and other islands, a rennet is made of a strong decoction of nettles: a quart of salt is put to three pints of the decoction, and bottled up for use. A common spoonful of this liquor will coagulate a large bowl of milk very readily and agreeably. The stalks of nettles are so like in quality to hemp, that in some parts of Europe and Siberia they have been manufactured into cloth, and paper has been made of them. The whole plant, particularly the root, is esteemed to be diuretic, and has been recommended in the jaundice and nephritic complaints. The roots boiled will dye yarn of a yellow colour. The larvæ, or caterpillars, of many species of butterflies, feed on the green plant; and sheep and oxen will readily eat it dried.

USAGE, in law, differs from custom and prescription: no man may claim a rent, common, or other inheritance, by usage, though he may by prescription. B. Co. 65.

USANCE, in commerce. See INTEREST.

USE, is a trust and confidence reposed in another who is tenant of the land, that he shall dispose of the land according to the intention of cestuy que use, or him to whose use it was granted, and suffer him to take the profits. 2 Black. 328.

By stat. 27 H. VIII. c. 10, commonly called the statute of uses, or the statute for transferring uses into possession, the cestuy que use is considered as the real owner of the estate; whereby it is enacted that, when any person is seized of lands to the use of another, the person intitled to the use in fee simple, fee-tail, for life or years, or otherwise, shall stand and be seized or possessed of the land, in the like estate, as he has of the use, trust, or confidence; and thereby the act makes cestuy que use complete owner both at law and in equity. 2 Black. 302.

USES, *superstitious*. See MORTMAIN.

USES *and customs of the sea*, are certain maxims or rules which form the basis of the maritime jurisprudence, by which the policy of navigation, and the commerce of the sea, are regulated.

These uses and customs consist of three kinds of regulations: the first called the laws or judgments of Oleron; the second, regulations made by the merchants of Wisbuy, a city in the island of Gothland, in the Baltic, antiently much famed for commerce; and the third, a set of regulations made at Lubec, by the deputies of the Hanse towns.

USQUEBAUGH, a strong compound liquor, chiefly taken by way of dram.

There are several different methods of making this liquor; but the following is esteemed one of the best: To two gallons of brandy, or other spirit, put a pound of Spanish liquorice, half a pound of raisins of the sun, four ounces of currants, and three of sliced dates; the tops of balm, mint, savoury, thyme, and the tops of the flowers of rosemary, of each two ounces; cinnamon and mace, well bruised, nutmegs, aniseeds, and coriander-seeds, bruised likewise, of each four ounces; citron, or lemon and orange peel, scraped, of each an ounce: let all these infuse forty-eight hours in a warm place, often shaking them together: then let them stand in a cool place for a week: after which the clear liquor is to be decanted off, and to it are to be put an equal quantity of neat white port, and a gallon of canary; after which it is to be sweetened with a sufficient quantity of double-refined sugar.

USTERIA, a genus of plants of the class and order monandria monogynia. The calyx is four-toothed; corolla funnel-form, four-toothed; capsule one-celled, two-seeded. There is one species, a shrub of North Guinea.

USURY, in a strict sense, is a contract upon the loan of money, to give the lender a certain profit for the use of it, upon all events;

whether the borrower made any advantage of it, or the lender suffered any prejudice for want of it, or whether it shall be repaid on the appointed time or not; and in a large sense, it seems, that all undue advantages, taken by a lender against a borrower, came under the notion of usury. Haw. 245.

The statute 12 Anne, c. 16, enacts that no person, upon any contract which shall be made, shall take for loan of any money, wares, &c. above the value of 5*l.* for the forbearance of 100*l.* for a year; and all bonds and assurances for the payment of any money to be lent upon usury, whereupon or whereby there shall be reserved or taken above five pounds in the hundred, shall be void; and every person who shall receive, by means of any corrupt bargain, loan, exchange, shift, or interest, of any wares or other things, or by any deceitful way, for forbearing or giving day of payment for one year, for their money or other things, above 5*l.* for 100*l.* for a year, &c. shall forfeit treble the value of the moneys or other things lent.

But if a contract, which carries interest, is made in a foreign country, our courts will direct the payment of interest according to the law of that country in which the contract was made. Thus Irish, American, Turkish, and Indian interest, have been allowed in our courts, to the amount each of 12*l.* per cent. For the moderation or exorbitance of interest depends upon local circumstances; and the refusal to enforce such contracts would put a stop to all foreign trade. 2 Black. 463.

In an action brought for usury, the statute made against it must be pleaded; and in pleading an usurious contract as a bar to an action, the whole matter is to be set forth specially, because it lies within the party's own privity; yet on an information on the statute for making such contract, it is sufficient to mention the corrupt bargain generally, because matters of this kind are supposed to be privily transacted; and such information may be brought by a stranger. 1 Hawk. P. C. 248. Likewise upon an information on the statute against usury, he that borrows the money may be a witness, after he has paid the same.

UTENSILS, in a military sense, are necessaries due to every soldier, and to be furnished by his host where he is in quarters, viz. bed with sheets, a pot, a glass or cup to drink out of, a dish, a place at the fire, and a candle.

Utensils, &c. directed to be provided for the use of regimental hospitals:

In page 19, of the Regulations for the Sick, it is stated, that each hospital ought to be furnished with a slipper-bath, or bathing-tub, two water-buckets, one dozen of Osnaburgh towels, one dozen of flannel cloths, half a dozen of large sponges, combs, razors, and soap; two large kettles, capable of making soup for 30 men, two large tea-kettles, two large tea-pots, two saucepans, 40 tin cans of one pint each, 40 spoons, one dozen of knives and forks, two close-stools, two bed-pans, and two urinals.

A regiment consisting of 1000 men, and provided with three medical persons, ought to be furnished with hospital necessaries and utensils for at least 40 patients. It should be provided with 40 cotton night-caps; 40 sets of bedding, in the proportion of four for every hundred men; each set consisting of one paillasse, one straw mattrass, one bolster, three sheets, two blankets, and one rug.

For regiments of smaller number, the quantity of hospital necessaries will of course be proportionally reduced.

Utensils, *bakery*. The following list of bakery utensils, being the proportion requisite for an army of 36,000 men, has been extracted from the British Commissary, to which useful treatise we refer the military reader for a specific description of field ovens, &c. and field bakery, page 16, &c.

12 double iron ovens, 11 feet long, 9 feet diameter, and 3 feet high; 28 troughs and their covers, 16 feet long, 3 feet wide, and 3 feet deep, to knead the dough.

12 large canvas tents (having double coverings), 32 feet long, and 24 feet wide, to make the bread in.

4 ditto, to cool and deposit the bread in.

2 ditto, to deposit the meal and empty sacks in.

2000 boards, 8 feet long, and 1½ foot wide, to carry the bread to the oven, and back when baked; 24 small scales to weigh the dough, with weights from half an ounce to 6lb.; 24 small lamps for night work; 24 small hatchets; 24 scrapers, to scrape the dough from the troughs; 12 copper kettles, containing each from ten to twelve pails of water; 12 trevets for ditto; 12 barrels with handles, to carry water, containing each from 6 to 7 pails.

12 pails, to draw water; 24 yokes and hooks, to carry the barrels by hand; 24 iron peles, to shove and draw the bread from the ovens; 24 iron pitchforks, to turn and move the firewood and coals in the ovens; 24 spare handles, 14 feet long, for the peles and pitchforks; 24 rakes, with handles of the same length, to clear away the coals and cinders from the ovens; 4 large scales, to weigh the sacks and barrels of meal, and capable of weighing 500lb.; 4 triangles for the said scales; to each must be added 500lb. of weights, 3 of 100lb. each, 2 of 50lb. each, and downwards to half a pound.

UTERUS. See Anatomy.

UTLAGATO *capiendo quando utlagatur in uno comitatu et postea fugit in alium.* A writ for the taking of an outlawed person in one county, who afterwards flies into another.

UTRICULARIA, a genus of plants of the class diandria, and order monogynia; and in the natural system arranged under the 24th order, corydales. The calyx is ringent, with a nectarium resembling a spur; the corolla diphyllous and equal; the capsule unilocular. There are 13 species, two of which are natives of Britain. They have been applied to no particular use.

UVARIA, a genus of plants of the class and order polyandria polygamia. The calyx is three-leaved; petals six; berries numerous, pendulous, four-seeded. There are eleven species, shrubs and trees of the East Indies.

VULTUR, a genus of birds belonging to the order of accipitres. The beak is straight, and crooked at the point; the head has no feathers, on the fore part there being only naked skin, and the tongue is generally bifid. There are twenty-one species. The most remarkable are,

1. Gryphus, the condor, which is not only the largest of this genus, but perhaps of all which are able to fly. The accounts of authors in regard to the strength of this bird, and its extent of wing, are various. From nine to eighteen feet from the tip of one wing to that of the other has been mentioned; and one gives it strength sufficient to carry off sheep, and boys of ten years old; while another ventures to affirm, that it can lift an elephant from the ground high enough to kill it by the fall! The account, however, given in Cook's Voyage, is very nearly, if not precisely, the truth, which states the extent of wing at about 11 feet. The bill is strong, moderately hooked, and blunt at the tip, which is white, the rest of it being of a dusky colour. On the top of the head runs a kind of carunculated substance, standing up like the comb of a cock. The head and neck are slightly covered with brown down, in some parts nearly bare, and here and there a carunculated part, as in the neck of a turkey. The lower part of the neck is surrounded with a ruff of a pure white and hairy kind of feathers. The upper parts of the body, wing, and garl, are black, except that the middle wing-coverts have whitish ends, and the greater coverts half black half white. The nine or ten first quills are black; the rest white, with the tips only black; and when the wings are closed, producing the appearance of the bird having the back white. The under parts of the body are rather slightly covered with feathers; but those of the thighs are pretty long. The legs are stout and brown; claws black and blunt.

These birds are said to make their nests among the inaccessible rocks, and to lay two white eggs, larger than those of a turkey; are very destructive to sheep, and will in troops often attempt calves; in which case, some of them first pick out the eyes, whilst others attack the poor animal on all sides, and soon tear him to pieces. This gives rise to the following stratagem, used by the peasants of Chili: One of them wraps himself up in the hide of a fresh-killed sheep or ox, and lies still on the ground; the condor, supposing it to be lawful prey, flies down to secure it, when the person concealed lays hold of the legs of the bird, his hands being well covered with gloves; and immediately his comrades, who are concealed at a distance, run in, and assist to secure the depredator, by falling on him with sticks till they have killed him.

2. The percnopterus, or Egyptian vulture. The appearance of this bird is as horrid as can well be imagined, viz. the face is naked and wrinkled; the eyes are large and black; the beak black and hooked; the talons large, and extending ready for prey; and the whole body polluted with filth: these are qualities enough to make the beholder shudder with horror. Notwithstanding this, the inhabitants of Egypt cannot be thankful enough to Providence for this bird. All the places round Cairo are filled with the dead bodies of asses and camels; and thousands of these birds fly about, and devour the carcases before they putrify and fill the air with noxious exhalations. The inhabitants of Egypt, and after them Maillet in his Description of Egypt, say, that they yearly follow the caravan to Mecca, and devour the

filth of the slaughtered beasts, and the carcases of the camels which die on the journey. They do not fly high, nor are they afraid of men. If one is killed, all the rest surround him in the same manner as do the Royston crows; they do not quit the places they frequent, though frightened by the explosion of a gun, but immediately return thither.

3. The aura, or carrion vulture, according to Latham, is about the size of a turkey, though it varies in size in different parts. The bill is white; the end black; irides bluish saffron-colour. The head, and part of the neck, are bare of feathers; and of a red, or rather rufous colour. The sides of the head warted, not unlike that of a turkey. The whole plumage is brown-black, with a purple and green gloss in different reflections; but in some birds, especially young ones, greatly verging to dirty-brown. The feathers of the quills and tail are blacker than the rest of the body. The legs are flesh-colour; the claws black.

4. The sagittarius, or secretary, is a most singular species, being particularly remarkable from the great length of its legs; which at first sight would induce one to think it belonged to the grallæ, or waders; but the characters of the vulture are so strongly marked, as to leave no doubt to which class it belongs. The bird, when standing erect, is full three feet from the top of the head to the ground. The bill is black, sharp, and crooked, like that of an eagle; the head, neck, breast, and upper parts of the body, are of a bluish ash-colour: the legs are very long, stouter than those of a heron, and of a brown colour; claws shortish, but crooked, not very sharp, and of a black colour; from the hind-head springs a number of long feathers, which hang loose behind like a pendant crest; these feathers arise by pairs, and are longer as they are lower down on the neck; this crest the bird can erect or depress at pleasure; it is of a dark colour, almost black; the webs are equal on both sides, and rather curled; and the feathers, when erected, somewhat incline towards the neck; the two middle feathers of the tail are twice as long as any of the rest. This singular species inhabits the internal parts of Africa, and is frequently seen at the Cape of Good Hope. It is also met with in the Philippine islands.

As to the manners of this bird, it is on all hands allowed that it principally feeds on rats, lizards, snakes, and the like; and that it will become familiar: whence Sonnerat is of opinion that it might be made useful in some of our colonies, if encouraged, towards the destruction of those pests. They call it at the Cape of Good Hope stangeater, *i. e.* snake-eater. A great peculiarity belongs to it, perhaps observed in no other; which is, the faculty of striking forwards with its legs, never backwards. Dr. Solander saw one of these birds take up a snake, small tortoise, or such-like, in its claws; when dashing it thence against the ground with great violence, if the victim was not killed at first, it repeated the operation till the end was answered; after which it ate it up quietly. Dr. J. R. Forster mentioned a further circumstance, which he says was supposed to be peculiar to this bird; that should it by any accident break the leg, the bone would never unite again.

The Editor of this work saw a secretary some years ago at Exeter-exchange. The dexterity with which it struck eels, &c. with its hard heel was surprising. How far it might have been tutored to this exercise is impossible to say.

5. The papa, or king vulture, inhabits South America; is the size of a hen turkey: feeds on serpents, lizards, frogs, rats and carrion; flies high. See Plate Nat. Hist. fig. 420.

VULVA. See Anatomy.

UVULA. See Anatomy.

UVULARIA, a genus of the hexandria monogynia class of plants, the flower of which consists of six very long lanceolated petals; and its fruit an ovate-oblong trilocular capsule, containing several roundish and compressed seeds. There are six species.

W.

W, or w, is the twenty-first letter of our alphabet.

WACHENDORFIA, a genus of plants of the class triandria, and order monogynia; and arranged in Linnæus's natural method of classification under the 6th order, ensatæ. The corolla is hexapetalous, unequal, and situated below the germen; the capsule trilocular and superior. There are five species, none of which are natives of Britain.

WACKEN, a mineral that occurs in mass; sometimes it forms strata, but more frequently it runs in veins. Colour dark greenish-grey, which often passes to mountain-green, or blackish-green. Specific gravity from 2.5 to 2.9. Easily melts before the blowpipe. Liable to spontaneous decomposition.

WAD, or Wadding, in gunnery, a stopple of paper, hay, straw, old rope-yarn, or tow, rolled firmly up like a ball, or a short cylinder, and forced into a gun upon the powder to keep it close in the chamber; or put up close to the shot, to keep it from rolling out, as well as, according to some, to prevent the inflamed powder from dilating round the sides of the ball, by its windage, as it passes along the chace, which it was thought would much diminish the effort of the powder. But, from the accurate experiments lately made at Woolwich, it has not been found to have any such effect.

WAFERS or Sealing-Wafers, are made thus: Take very fine flour, mix it with white of eggs, isinglass, and a little yeast; mingle the materials; beat them well together; spread, the batter being made thin with gum-water, on even tin plates, and dry them in a stove; then cut them out for use.

You may make them of what colours you please, by tinging the paste with brazil or vermilion for red; indigo or verditer, &c. for blue; saffron, tumeric, or gambooge, &c. for yellow.

WAGER OF LAW, is a particular mode of proceeding, whereby in an action of debt brought upon a simple contract between the parties, without any deed or record, the defendant may discharge himself by swearing in court in the presence of compurgators, that he owes the plaintiff nothing, in manner and form as he has declared, and his compurgators swear that they believe what he says is true. And this waging his law, is sometimes called making his law. 5 Bac. Abr. 428.

It being at length considered, that this waging of law offered too great a temptation to perjury, by degrees new remedies were devised, and new forms of action introduced, wherein no defendant is at liberty to wage his law.

Instead of an action of debt upon a simple contract, an action is now brought for the breach of a promise, or assumpsit; wherein though the specific debt cannot be recovered, yet damages may, equivalent to the specific debt; and this being an action of trespass, no law can be waged therein. So instead of an action of detinue to recover the very thing detained, an action of trespass upon the case, in trover and conversion, is usually brought, wherein though the specific thing cannot be had, yet the defendant shall pay damages for the conversion equal to the value thereof: and for this trespass also no wager of law is allowed. In the place of actions of account, a bill in equity is usually filed, wherein, though the defendant answers upon his oath, yet such oath is not conclusive to the plaintiff, but he may prove every article, by other evidence, in contradiction to what the defendant has sworn. So that wager of law is now quite out of use, being avoided by the mode of bringing the action, but still is not out of force. And therefore when a new statute inflicts a penalty, and gives an action of debt, it is usual to add that no wager of law will be allowed.

WAGERS. In general a wager may be considered as legal, if it is not an incitement to a breach of the peace, or to immorality; or if it does not affect the feelings or interest of a third person, or expose him to ridicule: or if it is not against sound policy. 2 Durnf. & East, 610. See Insurance.

WAGES, what is agreed upon by a master to be paid to a servant, or any other person that he hires to do his business for him. 2 Lil. Abr. 677. See MASTER AND SERVANT.

WAGTAIL, in ornithology. See MOTACILLA.

WAIFS, are goods which are stolen and waved by a felon in his flight from those who pursue him, which are forfeited; and though waif is generally spoken of goods stolen, yet if a man is pursued with hue and cry as a felon, and he flees and leaves his own goods, these will be forfeited as goods stolen; but they are properly fugitive's goods, and not forfeited till it is found before the coroner, or otherwise of record, that he fled for the felony. 2 Haw. 450. See ESTRAYS.

WAINAGE. The reasonableness of fines or amercements having been regulated by Magna Charta, that no person shall have a larger amercement imposed upon him than his circumstances or personal estate will bear, it is added, saving to the freeholder his contenement or land; to the trader his merchandize; and to the countryman his wainage, or team and instruments of husbandry. 4 Black. 379.

WAIVER, in law, signifies the passing by of a thing, or a refusal to accept it; sometimes it is applied to an estate, or something conveyed to a man, and sometimes to plea, &c. And a waiver or disagreement as to goods and chattels, in case of a gift, will be effectual. Lil. 710.

WAKE *of a ship*, is the smooth water astern when she is under sail: this shews the way she has gone in the sea, whereby the mariners judge what way she makes. For if the wake is right astern, they conclude she makes her way forwards; but if the wake is to leeward a point or two, then they conclude she falls to the leeward of her course. When one ship, giving chase to another, is got as far into the wind as she, and sails directly after her, they say she has got into her wake. A ship is said to stay to the weather of her wake, when in her staying she is so quick, that she does not fall to leeward upon a tack; but that when she is tacked, her wake is to the leeward; and it is a sign she feels her helm very well, and is quick of steerage.

WALE, or WALES, in a ship, those outermost timbers in a ship's side on which the sailors set their feet in climbing up. They are reckoned from the water, and are called her first, second, and third wale, or bend. See SHIP.

WALES. By stat. 27 H. VIII. c. 26, and other subsequent statutes, the dominion of Wales shall be incorporated with, and be part of, the realm of England; and all persons born in Wales shall enjoy all liberties and privileges as the subjects in England do. And the lands in Wales shall be inheritable after the English tenure, and not after any Welsh laws or customs. And the proceedings in all the law-courts shall be in the English tongue. A session is also to be held twice a year in every county, by judges appointed by the king, to be called the great sessions of the several counties in Wales; in which all pleas of real and personal actions shall be held, with the same form of process, and in as ample manner, as in the court of common-pleas at Westminster; and writs of error shall lie from judgments therein to the court of king's-bench at Westminster. But the ordinary original writs, or process of the king's courts at Westminster, do not run into the principality of Wales, though process of execution does, as also all prerogative writs, as writs of certiorari, quo minus, mandamus, and the like. 3 Black. 77.

Murders and felonies in any part of Wales may be tried in the next adjoining English county; the judges of assize having a concurrent jurisdiction throughout all Wales, with the justices of the grand sessions. Str. 553.

All local matters arising in Wales, triable in the king's-bench, are by the common law to be tried by a jury returned from the next adjoining county in England. Burr. 859.

No sheriff or officer in Wales shall, upon any process out of the courts at Westminster, hold any person to special bail, unless the cause of action is twenty pounds or upwards. 11 and 12 W. c. 9.

WALK. See GARDENING.

WALKERIA, a genus of plants of the class and order pentandria monogynia. The calyx is five-parted, inferior; corolla five-petalled; drupes five, one-seeded; nuts reniform. There is one species, a tree of the East Indies.

WALL, in gardening. Of all materials for building walls for fruit-trees, brick is the best, it being not only the handsomest, but the warmest and kindest for the ripening of fruit; and affording the best conveniency for nailing, as smaller nails will serve in brick than will in stone walls, where the joints are larger; and if the walls are caped with free-stone, and stone pilasters or columns at proper distances, to separate the trees, and break off the force of the winds; they are very beautiful, and the most profitable walls of any others. In some parts of England there are walls built both of brick and stone, which are found very commodious. The bricks of some places are not of themselves substantial enough for walls; and therefore some persons, that they might have walls both substantial and wholesome, have built these double, the outside being of stone, and the inside of brick; but there must be great care taken to bond the bricks well into the stone, otherwise they are very apt to separate one from the other, especially when frost comes after much wet.

There have been several trials made of walls built in different forms; some of them having been built semicircular; others in angles of various sizes; and projecting more towards the north, to screen off the cold winds; but there has not as yet been any method which has succeeded near so well as that of making the walls straight, and building them upright. Where persons are willing to be at the expence in the building of their walls substantial, they will find it answer much better than those which are slightly built, not only in duration, but in warmth; therefore a wall two bricks thick will be found to answer better than that of one brick and a half. The best aspect for ripening fruit is south, with a point to the east; and the next best due south. It is a great improvement to have a trellis of wood against the wall, to train the trees to, as it prevents the wall being spoiled by nails, &c.

WALLENIA, a genus of plants of the class and order tetrandria monogynia. The calyx is four-cleft; corolla tubular, four-cleft; berry one-seeded. There is one species, a tree of the West Indies.

WALRUS. See TRICHECUS.

WALNUT-TREE. See JUGLANS.

WALTHERIA, a genus of the monadelphia pentandria class of plants, the flower of which consists of five petals, vertically cordated and patent; the fruit is an unilocular bivalve capsule, vertically ovated; and the seed is single, obtuse, and broadest at the top. There are six species.

WANMANNIA, a genus of plants of the class octandria, order monogynia, and arranged in the natural classification with those plants the order of which is doubtful. The calyx is four-leaved, the corolla has four petals, and the capsule is bilocular and birostrated. There are four species, none of which are natives of Britain.

WAPENTAKE, from the Saxon, the same with what we call a hundred, and more especially used in the northern counties beyond the river Trent. There have been several conjectures as to the original of the word, one of which is, that antiently musters were made of the armour and weapons of the inhabitants of every hundred; and from those that could not find sufficient pledges of their good behaviour, their weapons were taken away, and given to others; whence it is said this word is derived. See HUNDRED.

WAR. The too frequent recurrence of this great and detestable calamity, unfortunately renders a definition of the word unnecessary. If we were called upon to define it, we should say, it is the wanton destruction, the cold-blooded slaughter, of the human race: we should call it an accumulation of every sin that degrades and vilifies mankind: we should mark it as a practice that diffuses misery and perpetuates vice: we should say, that if there is a burlesque upon the boasted reason of man it is this; when millions meet to murder each other for a quarrel in which, in general, they have not individually the smallest interest. The poet who wrote,

> "One murder makes a villain, millions a hero," &c.

deserves a statue of gold; and the writer of that verse may lift his head in the proudest assembly, and avow his principles in the face of the world.

The best and most respectable of the Christian sects have disclaimed war as inconsistent with their Christian calling and profession. There may however exist cases where war is self-defence; and if ever it is such, it is when an unprincipled tyrant, at the head of a disciplined banditti, endeavours to reduce the civilized world under one system of general despotism, and to plunder the property of unoffending nations and individuals, in the same manner as the highwayman, who by the laws of every well regulated community, is for such an offence destined to the rope. We leave our readers to make the application to the present circumstances of Europe, and we think they cannot long be at a loss.

In this view, as a means of defence, and as useful to the understanding of history, and not as giving our sanction to an irrational and antichristian practice, we insert the following article.

WAR, *art of*. As war, on the one hand, in respect to its effects, is intimately connected with the propriety and independance of nations; so, on the other, it requires infinite skill, combination, and management, when considered as an art. Its principles, founded on the sciences themselves, are fixed and certain: but these branch out into such a prodigious variety of ramifications, that men of extraordinary talents and genius only have been able to excel in it.

As two different elements constitute the theatre of its operations, war is naturally divided into naval and military arrangements.

Of naval warfare.

The art of arranging squadrons or fleets in order of battle, and regulating their movements in such a manner as may be deemed best calculated for attacking, defending, or retreating, to the greatest possible advantage, is termed naval tactics.

The antients seem to have excelled rather in land, than in sea engagements. On recurring to the history of remote periods, we are perpetually reminded of the state of savage nations at the present day; the canoes indeed of the Iroquois would have availed but little, yet the war-boats of Otaheite might not then have appeared contemptible.

The Mediterranean was the early scene of naval exploits; and galleys were the vessels originally used in engagements. These were propelled by the force of oars; and the combatants being made to approach, and sometimes to board each other by means of flying bridges, a battle at sea differed but little from a battle on land. But in progress of time, a superiority was attempted to be obtained by means of skill and management. The prows were armed with brazen spikes, or tridents, which were so contrived as to pierce the enemy's vessels under water, and by letting in the sea, expose them to the danger of sinking. Turrets were also erected between the poop and the forecastle, for the purpose of overlooking the foe, and annoying him by means of darts and slings. In process of time, other improvements took place, which we shall here endeavour briefly to enumerate.

1. The dolphin, which was a huge and massive piece of lead, formed into the shape of the fish from which it had derived its name. This being perfectly suspended by blocks and ropes from the mast-head or yard-arm, was allowed to drop, whenever an opportunity presented itself; and penetrating through the bottom of a vessel slightly constructed, it of course, by its own specific gravity, made a passage for the entering waves; and thus sometimes rendered even a retreat impossible.

2. Another engine in use, consisted of a scythe of iron, fixed at the top of a long pole; and was employed for the purpose of cutting asunder the slings of the sail-yards, so as to incommode during action, and prevent escape either then or afterwards.

3. Spears, or maces, of an extraordinary length, were constructed so as to annoy at a considerable distance; and thus, although stationary, to serve the purpose of a missile weapon.

4. The naval battering-ram, mentioned by Vegetius, consisted of a long beam, armed with a head of iron; and being suspended to the main-mast, was employed to good effect against the sides of the galleys.

5. A grappling-iron, which seized hold of any part of the opposing vessel, and facilitated the boarding of her.

6. The last, and most formidable of all their machines, was the balista; by which large stones could be thrown to a great distance, with a considerable degree of certainty, and the most terrible effects.

3

Having thus mentioned the engines made use of by the antients during naval combats, we next come to the disposition of their fleets. It was then, as now, considered a great advantage to obtain the weather-gage; and it was at the same time endeavoured to contrive so as to have the sun behind themselves, while it shone directly in the faces of their enemies. Instead of manœuvring by means of their sails, these were always lowered previously to action; and the prows being presented to the enemy, they advanced against each other by force of oars, and amidst the sound of trumpets. After expending their arrrows and javelins, recourse was at length had to the sword, so that courage alone decided the combat.

The code of signals, like the symbol by which they were regulated, was simple in the extreme. It consisted sometimes of a gilded shield, and sometimes of a red garment, or banner. During the elevation of this, the battle continued; its depression denoted defeat; and by its inclination either to one side or the other, an attack or retreat was pointed out.

In respect to the line of battle, the half-moon was generally the favourite position. During one memorable sea-fight, the galleys of the Romans were ranged so as to represent a wedge in front, while the Carthaginians drew up their fleet in such a manner as to form a rectangle on two sides of a square, for the purpose of annoying and inclosing the flank of the enemy; the former was the figure best calculated for attack, the latter for defence.

Notwithstanding the boasted greatness of the Roman people, yet when this country was invaded by Cesar, they appear to have obtained but little eminence in respect to naval affairs. A fleet on that occasion was not brought from the mouth of the Tiber, and the vessels built in Gaul exhibited nothing formidable or ingenious either in their management or construction. They must have been small and contemptible, in point of size, for they were drawn up on the beach, near to where the town of Deal now stands, and fortified like the camp, by means of a ditch and rampart.

On the departure of these invaders, who, as usual, at once conquered and civilized the barbarous tribes among whom they settled, the situation of the Britons must have been truly distressing. Reduced perhaps to the coracles, or boats made of skins stretched on osiers, they were able to derive little or no benefit from the ocean that surrounded them. On the neighbouring continent, however, the boats had made a greater progress, or at least left a deeper impression; for, doubtless, the keels of the Saxons must have appeared formidable to men whose vessels were ribbed with twigs.

The wars with the Danes rendered some attention to maritime affairs necessary; and Alfred is represented as having encouraged and employed foreign artificers and mariners, by means of whom he constructed vessels of a superior size. With these he scoured the coasts, which were then infested by pirates, freebooters, and enemies of all sorts: and this prince appears to have rescued his subjects from the incursions of pirates.

At length the depredations of the northern states became formidable. From being occasional visitors, for the sake of plunder, the Danes, and other nations bordering on the Baltic, began to think of settling in Britain, and in consequence of their power and numbers, they were finally enabled to place one of their own sovereigns on the throne. After this, either by land or sea, all contention necessarily ceased.

William the Norman obtained the crown by the gross mismanagement of Harold, in respect to both naval and military affairs: for on one hand he had detached his squadron to the northern parts of the kingdom, instead of keeping it on the southern shore to oppose the enemy; while on the other he put his whole stake to hazard on a single battle. The fleet conducted by the Conqueror to the coast of Sussex, (Sept. 28, 1066) consisted of no less than three hundred vessels; but they appear to have been contemptible in point of size, and to have been but ill calculated to cope with an enemy.

A long interval succeeded before any great progress, in respect to maritime affairs, occurred; and the crusades, the wars between the kings and the barons, the acquisition of Ireland, and the incorporation of Wales, all took place before the foundation of a national navy was laid. But commerce, the true nursery of sailors and of a fleet, began to be attended to; trade was no longer carried on solely by foreigners; while the wool of England, after being woven and spun where it had grown, was exported to distant countries, and brought back profitable returns. The ships of the cinque-ports now became formidable; they were regularly lent out, when required, to the kings of England; and assisted not only in their wars, but in the conveyance of their troops to the continent.

In 1217, Hubert de Burgh, governor of Dover-castle, after obtaining the weather-gage, defeated the French, in the first sea-fight that ever took place between the English and them.

It was not until the time of Edward I. however, that any great exertions seem to have taken place. That prince fitted out three squadrons at the same time.

In 1340, the English fleet appears to have been drawn up in two distinct lines, the larger ships being placed in the front, and the smaller in the rear, whence they were enabled to send fresh supplies of men, or otherwise grant their assistance, as occasion might serve. In this battle, which took place on the coast of Flanders, the French lost two hundred and thirty ships, and had two of their admirals slain. During the contest for the crown of France, the arms of England were eminently triumphant both by sea and land; but the wars between the rival houses of York and Lancaster so completely occupied the hands and the hearts of the nation, as to prevent any attention to foreign affairs.

At length Hen.VII. a wise and able prince, began to build ships of war, one of which cost him upwards of 14000*l*. His son, Henry VIII. notwithstanding those odious vices which rendered his memory odious, seems to have conceived a just notion of the true interests of the nation, in respect to maritime affairs. He accordingly instituted the navy-office, appointed commissioners, constructed several large ships, and laid the foundation of that naval power, which, in the time of his daughter, preserved the independance, and added not a little to the glory, of England.

Nor were the French at this period inattentive to their navy. During an engagement with the English in the Channel, their fleet appears to have assumed a regular and systematical arrangement. It consisted of three divisions, that in the centre being composed of thirty-six ships, and the van and rear of thirty each. The galleys, which had come from the Mediterranean, were considered in the same point of view as frigates are at the present day, and never entered the line of battle.

Meanwhile, the introduction of gunpowder had created an entire change in the weapons of war; and at this day the sword and the boarding-pike are perhaps the only ones that have been used in common, both by the antients and moderns. The Spaniards, who had become a great maritime nation, are said to have been the first who had recourse to cannon, during a sea-fight with the English and their allies, off Rochelle, in 1372: yet it has been asserted, that this instrument of destruction was actually recurred to by our ancestors in 1350. The same people soon after threatened an invasion, by means of an armada, which, whether we consider the size of the vessels, or the manner in which they were manned and equipped, must be considered as truly formidable. They entered the Channel in the form of a crescent, the horns of which extended to a prodigious distance, and were assuredly more than a match for any force that could be brought to oppose them. But lord Howard of Effingham, assisted by Drake, Hawkins, and Frobisher, (all of whom, but himself alone, had been bred in the merchant-service), so managed an inferior squadron, as to obtain a complete victory.

A competent idea may be formed of the fleet of England in those days, by observing, that on the demise of Elizabeth, it consisted of forty small ships only, of which number four did not exceed forty guns, and but two of these were of the burthen of a thousand tons; twenty-three others were below five hundred; of the rest, some did not exceed fifty, and some not even twenty, while the whole number of guns amounted to no more than 774.

But the long and bloody contest that afterwards took place with Holland for naval superiority, finally fixed the character of the English nation, in respect to maritime affairs. During three dreadful wars, there were no less than nineteen general engagements, in one of which the fight was renewed for three days in succession, in another for two days, and in a third for one; making in all no less than twenty-five days of general actions. What is still more extraordinary, De Witt on one side, and Monk and Blake on the other, were landsmen, yet they all fought with unrivalled skill and intrepidity. The last of these was the first who ever brought ships of war to oppose castles.

At the death of Charles II. the royal navy amounted in all to 113 sail. James II. while a subject, had commanded a fleet, and instituted, or rather improved and enlarged, the system of signals. At his abdication, England possessed 173 vessels of different descriptions. During the time of William and Mary, these were increased to 256; but their success was not proportionable to the public expectation. In the reign of Anne, however, the naval power of France received a deadly blow at Vigo, having lost no less than seventeen ships of war.

On the accession of the house of Brunswick, the fleet increased rapidly; and during the present reign, it has obtained an unexampled degree of prosperity: for towards the middle of the year 1806, it consisted of 132 sail of the line, 17 forty-four and fifty gun ships, 196 frigates, 106 sloops, &c. and 242 gun-brigs, forming a total of 753 in commission.

After these observations on the rise and progress of the British navy, it may be necessary to make some remarks on the manner in which it is conducted during action. As the skill and bravery of our seamen have always been eminent by comparison in close engagements between single ships, it necessarily follows, that the adoption of any system which would place fleets precisely in the same condition, could not fail to be attended with the most beneficial advantages. It was a long while, however, before this could be effected; for the opposite squadrons being usually disposed in right lines parallel to each other, every ship keeping close hauled upon a wind on the same tack, it necessarily followed, that the action in general, provided equal numbers were brought into contact, could neither be long nor decisive. Thus it frequently happened, that nothing decisive occurred, not so much as a single ship being lost or won on either side.

A great and sudden change was however effected. This occurred on the 12th of April 1782; when admiral sir George Bridges Rodney, instead of following the old system, pierced the French line, formed by the count De Grasse, and gained a complete victory. The same occurred under lord Howe, June 1, 1794.

A similar principle, viz. "the directing the greater part of the force of a fleet against a few ships," was put in practice by sir John Jervis, now earl St. Vincent, on the 13th of February, 1797.

At the battle of the Nile admiral sir Horatio, afterwards lord viscount, Nelson, contrived to double down on the enemy, and place part of their fleet between two fires: while during that of Trafalgar he advanced in two lines, and effected a disjunction with similar effect, but by different means. The principle, indeed, was exactly the same in all; that of bringing fleets into the same position as single ships, so that the sailors might be enabled to fight hand to hand, with the additional advantage, that the many would thus be enabled to attack the few.

It has already been observed, that some of our gallant naval commanders, during the civil wars, had been bred in the army; and it is not a little remarkable, that the great change which has taken place of late years, in respect to the management of fleets, appears to have originated with a landsman, who, according to his own account, had attained ten years of age, before he had ever seen a ship. The gentleman to whom we now allude is Mr. Clerk, of Eldin, author of an "Essay on Naval Tactics, Systematical and Historical, in four parts." The first edition of the first part appeared in 1790; and the second edition in 1804; and as this is the only treatise of the kind in our language, we shall here take some notice of it.

During the American war, the action between admiral Keppel and the French fleet, on the 27th of July, 1778, engaged Mr. Clerk's particular attention. The idea of the line of battle was in some parts novel, as it was an attack from the leeward; and he remarked, with surprise, that in the course of the two long trials which followed this indecisive fight, as well as that of admiral Matthews, in 1744, and of admiral Byng, in 1756, not a single hint escaped, "that it was possible any thing defective could be attributed to the system of the attack itself, or that any kind of improvement should be attempted;" such as the scheme since put in practice, "the cutting the enemy's line asunder; the directing the greater part of the force of a fleet against a few ships, either in the van or the rear, or even making a prize of the slower-sailing or crippled ships of the enemy."

During the engagement of admiral Byron off the island of Grenada, on July 6, 1779, the attack, like those made by Matthews and Byng, was from the windward; and from a consideration of all these cases, Mr. Clerk became induced to think, that the want of success was not to be attributed either to any abatement in the spirit of the seamen, or any defect in the shipping, or sailing of the fleets, but solely to the unskilful manner in which the general attacks were conducted.

Impressed with these ideas, he mentioned his suspicions, in January 1780, to a friend of sir George Rodney, to whom he at the same time communicated his theories of attack from both windward and leeward, and explained his doctrine of cutting the enemy's line. The propriety of these plans was not fully exemplified however, until two years after, (April 12, 1782;) when a victory, far more decisive and important than any which had been gained by our fleets during the last century, was obtained; for, on this occasion, the attack was from the leeward, which the author considers as more rare, ingenious, and effectual, than an attack from the windward; in addition to which, the enemy's line was at the same time cut in two.

In the Essay on Naval Tactics, the impropriety of a single ship to windward bearing down directly on an enemy to leeward, is pointed out by a diagram, accompanied with a demonstration: we are then presented with a comparative estimate of the effect of shot directed against the rigging of a ship, with its result when employed against the hull. In respect to fleets, an attack from the windward is supposed to be attended with a disadvantage in the ratio of twenty to one, as the fire of the whole line to leeward can be applied, on such an occasion, against the van of the assailants; a manœuvre which the French were well acquainted with, and put constantly in practice, until the new mode of combat was introduced.

These positions are illustrated by;

1. Admiral Matthews' engagement with the combined fleets of France and Spain, off Toulon, February 11, 1744.

2. Admiral Byng's action with the French fleet off Minorca, May 20, 1756.

3. Admiral Keppel's off Ushant, July 27, 1778.

4. Admiral Byron's off Grenada, July 6, 1779.

5. Admiral Barrington's, at St. Lucia.

6. Sir George Bridges Rodney's, off Capes Finisterre and St. Vincent.

7. ——————————— off the Pearl Rock, Martinico, April 17, 1780.

8. ——————————— to windward of Martinico, May 15, 1780.

9. ——————————— near the same place, May 19, 1780.

10. Admiral Arbuthnot's, off the Chesapeak, March 16, 1781.

11. Sir Samuel Hood's, off Fort Royal, Martinico, April 29, 1781.

12. Admiral Parker's, off the Doggerbank, August 5, 1781.

13. Commodore Johnstone's, at Port Praya, in the island of St. Julian.

14. Admiral Greaves's, off the Chesapeak, September 5, 1781.

From the particulars of this catalogue, Mr. Clerk deduces, as a general principle, that "where the British fleets being to windward, have endeavoured, by extending their line of battle, to stop, take, or destroy, the whole of the ships of the enemy's line to leeward, they have been disabled before they could reach a situation whence they could annoy the enemy; and, on the other hand, the French pursuing the British, in disorder, unsupported, and disabled, have made sail; and after throwing in the whole fire upon the van of the British fleet, ship by ship, as passing in succession, have formed a line to leeward, so as to be prepared in case another attack could be made."

He concludes by observing, "that the most artful management of sails, the closest approximation, or the most spirited cannonade, will avail nothing, under such circumstances; and that it is in vain to hope, that ever any thing material can be effected against an enemy's fleet keeping to windward, passing on contrary tacks, and desirous to go off, unless his line of battle can be cut in twain, or some such other step can be devised as has already been described."

Mr. Clerk, after this, proposes certain new modes, and points out their advantages:

1. The attack from the windward upon the rear of the enemy.

2. On the enemy's three sternmost ships.

He considers both of these as far preferable to the attempt of getting up with the enemy's van, with the view to carry the whole fleet; and thinks that we ought rather to content ourselves with the certainty of cutting off a few of their dullest-sailing vessels.

In Part II. we are presented with three cases of an attack: the 1st when made by the headmost ships of a squadron on the van of a retreating enemy; the 2d on or near the centre; and the 3rd upon the van, or any where ahead of the centre.

After due investigation, Mr. Clerk is of opinion, that the attack from the leeward quarter can be executed with the greatest number of advantages, particularly as the crippled ships remain under the protection of their friends; whereas, on the contrary, those appertaining to a fleet to windward, will fall immediately into the power of their enemies.

The battles which have taken place since the publication of this work, seem fully to justify all the positions laid down by this author, whose merits are acknowledged, and who, we are informed, has received encouragement and protection of the highest kind.

Of military arrangements.

The art of arranging armies in order of battle, and of regulating their movements in such a manner, as may be deemed most proper for attacking, defending, or retreating, to the greatest possible advantage, is termed military tactics. It has been generally recognised, and is at length received as an axiom, that there is no branch of human knowledge more difficult than that of which we are now about to treat; and both antients and moderns have been so well convinced of this fact, that it has been regularly taught in public schools, erected expressly for that purpose.

Two celebrated nations, the Greeks and the Romans, were particularly anxious to attain perfection in the science of war; and this accounts, in some measure, for their extraordinary success, when combating against enemies who, content with a blind obedience to a custom, placed their chief confidence, not in the discipline, but in the multitude of their combatants. They, on the contrary, were conscious that the strength of armies consists principally in the art with which they are managed, and the principles by which they are regulated; that multitudes are often more embarrassing than useful; and that a small body of troops, well regulated, and ably directed, is capable of overcoming a large one, deficient in respect to those advantages. Thence too they deduced a theory relative to the disposition of their soldiers, the order of battle, the manner of encamping, the best and most regular mode of marching, of forming, and of acting, in such a way, as to oppose the strong to the weak, while they at the same time anticipated all the stratagems, and prevented all the deceptions, of the enemy. On the other hand, they did not forget to regulate the different species of arms, to attain address in managing; and to adopt the most advantageous method of using them, whether offensively or defensively.

War, accordingly, was regarded as an art, of which it was necessary to become acquainted with the principles anterior to the practice. It is but little wonder, therefore, that so many great men were produced, and such wonderful effects ensured; more especially in Greece, where infinite pains were taken to attain a perfect system. The Romans too directed their attention to military affairs; and the order of the legion was supposed on the whole to be superior to that of the phalanx. Vegetius, indeed, after examining its formation, exclaims, that none but a God could have contrived such a powerful and admirable assemblage.

That wonderful nation too, laying prejudice aside, at once examined, studied, and adopted, those practices in which they were excelled by their enemies. A defeat was never lost on them; for after every reverse, they obtained an increase of their military knowledge. Thus the sharp-edged weapons of the Gauls, and the elephants of Pyrrhus, never surprised them but once; and they had no sooner become acquainted with the Spanish sword, than they immediately abandon their own. At the same time, they did not omit to employ Numidian horses, Cretan archers, slingers from the Balearic islands, and ships belonging to Rhodes. In fine, no people ever exhibited so much prudence in their preparations for a campaign, or carried on hostilities with such extraordinary audacity. We are the less inclined to wonder, therefore, at the observation of Josephus, who remarks, "that war with them was a meditation, and peace an exercise."

We accordingly find that they abound with great commanders; and what is still more extraordinary, that many of these commanders proved victorious without the benefit of experience. Scipio, at the age of twenty-seven, knew how to repair the faults committed by his father and his uncle, in consequence of previous study. When Lucullus marched into Asia for the purpose of attacking Mithridates, he instructed himself, according to Cicero, by reading Xenophon, and the best authors; while at a later period Narses, who had never before commanded, nor even served, replaced Belisarius, overcame Totila, and successfully concluded the struggle with the Goths.

It is evident, therefore, that war is to be regulated according to certain rules and principles; and that on the knowledge and application of these, depends the fate of a campaign, and perhaps of a nation. It necessarily follows, that a general ought to possess extraordinary talents and attainments. According to a celebrated author, "some qualities should be born with, and others acquired by, him." In addition to these, he should also possess a quick eye, so as to enable him to judge of an advantageous position for his troops, decide on a manœuvre to be made or to be avoided, of a country suitable or unsuitable to his army; and, above all, of a field of battle whence he can derive the greatest number of possible advantages at the least possible risk or inconvenience.

He should at the same time exhibit a sound and solid judgment; for the choice of officers to be employed on any particular exigency, depends in a great measure upon him, and therefore the best dispositions would prove fruitless if not ably seconded. As his orders too cannot, from the nature of things, be precise, it is expected therefore of those who command under him, to know how to take advantage of a wrong movement on the part of the enemy, to commence an attack themselves, or only to sustain the troops engaged, and to vary their conduct according to the varying nature of circumstances.

But these qualities in the chief without subordination on the part of those who are subject to his command would be of little avail, if order and discipline were not duly observed. Without these, the most numerous and best-composed army would soon become little better than a horde of Tartars, who, being united only by the hope of booty, separate as soon as that motive ceases to operate. Great art is necessary, however, in enforcing discipline, and a happy mean ought to be adopted. Too much severity disgusts the soldier, and not unfrequently produces mutinies; too much indulgence on the other hand sinks him into indolence, and induces him to neglect his duty; licentiousness makes good order appear burthensome; with his respect for, he also loses all his confidence in, his superior officer, so that the most fatal results are at length unavoidable.

Besides the above qualities, which are so essential, and even necessary, in a commander, a general who would aspire to the title of a hero, ought to unite in himself, not only all military, but all civil and political excellence. It is by a knowledge of the laws, customs, constitutions, produce, and nature of different states, that he is to regulate his operations, and make war with success. Nothing will escape him, because every thing is essential to his projects; the genius of the country points out the manner of his marches and his movements, and the knowledge of the inhabitants will lead him to anticipate whatever may be expected on their part. One nation is vehement, fiery, and formidable, at the first onset; another is not so hasty, but possesses more perseverance; with the former, a single instant determines success; with the latter, the action is not so rapid, but the event is less doubtful.

In former times, the art of war was different from what it is at present, although the grand principles are still the same. After the darts, javelins, and arrows, had been expended, the combat took place between opponents who engaged hand to hand; and as they advanced in deep order, with a view of overcoming all opposition by means of the impetus, the action was generally long and bloody. Some of the plans of battle were exactly the same then as now; and it is not a little remarkable, that Cæsar, at Pharsalia, drew up his troops according to the oblique order, while Epaminondas at Leuctra adopted that figure which, on account of its particular form, is called an echellon attack.

In the middle ages, war appears to have degenerated into a system of marauding, being carried on nearly in the same manner as among the Mahrattas at the present day. The troops, if troops they might be termed, were mounted on horseback; and the men at arms, as they were called, being cased in armour, placed their glory in standing erect in their stirrups, so as to resist the shock of an adversary. At length, during the crusades, a more regular system began to prevail; and the christians on the plains of Palestine, met with a master in the art of war, in the person of Saladin.

At the battle of Hastings, the Norman cross-bows appear to have galled and even to have surprised the English, whose ranks were close, and whose line could not be pierced. On perceiving this, William had recourse to stratagem, and conquered by pretending to fly, for he knew that regular order could not be preserved in a pursuit, and he was thus enabled to overcome an enemy which had been thrown into disorder.

At Cressy, the English army was formed in a masterly manner, having been posted to great advantage on a gentle ascent, near the village of that name, and drawn up so as to form three lines expressly according to the mode prevalent at the present day; while Edward III. was stationed with the reserve, so as to be able to see and to succour his troops, if occasion should require. The long bows of the English, at this memorable conflict, seem to have exhibited a marked superiority over the cross-bows of the Genoese, who had been many years considered as the best light troops in Europe. Since that period, the English, more especially when opposed hand to hand with the French, have uniformly maintained their superiority in the field, whenever equal numbers were engaged. We accordingly find, that whether with infantry or cavalry, the pike, the screwed bayonet, or sword, have in turn, while in their hands, been managed to advantage.

The introduction of gunpowder has made a great change in the art, without altering, however, any of its grand principles, which were exactly the same at the battles of Cannæ and of Austerlitz. This invention, however, has made modern wars infinitely more expensive, and modern armies far more difficult, in respect to their management. An immense quantity of baggage, ammunition, and artillery, has now become necessary, while the specific number rather than the individual excellence of the soldiers, is attended to. As much depends in the new system, on the regular supply of provisions, for men and horses, a plan of the campaign is formed beforehand, fortresses are considered as so many fundamental points, and the magazines being filled under their protection, they are termed the base whence the lines of operation are to be traced. It is thus, that strong places serve equally to protect retreats, and to favour attacks.

In ancient times, it was usual to assault the enemy in front, but it is now customary to act on the flank and the rear, to cut off convoys, and by annihilating his supplies, to destroy the resources on which he depends. It is usual, therefore, instead of assuming a position directly in front, to occupy a camp either to the right or left; for the centre, which is the strongest part of the line, is thus happily eluded, while on the contrary, the wings, which are necessarily the weakest portion, thus became exposed to insult.

Notwithstanding gunpowder is supposed by some to have been first used at the battle of Cressy, where two field-pieces are said to have been employed, yet it was not until the reign of Louis XIV. that towns began to be fortified according to the modern manner. Vauban, under the auspices of that monarch, rendered sieges long and expensive. During the war of the succession, Marlborough and Eugene perceived the necessity of obtaining possession of the fortresses on their flanks before they thought of advancing, while Charles XII. carried on war like a knight-errant, rather than a great general; for although the passage of the Dwina, the battle of Narva, and the actions in Poland displayed the talents of a master, yet his march into the Ukraine, at the solicitation of a Cossack chief, and his brilliant but delusive career, considered as one great whole, savour more of the adventurer than the hero.

It was about this period, that, in consequence of the frequency of sieges, the pike began to be entirely laid aside, and the bayonet adopted. The prince de Dessau soon after introduced three important changes, to two of which the Prussians were indebted for the battle of Molvitz. The first of these, the iron ramrod, by accelerating, tended not a little to render the fire of musquetry more fatal, and thus served to exempt it from the contempt in which it was held by the chevalier Folard and marshal Saxe. The second was the equal step, which enabled the whole line to advance in regular time, and thus produced one grand and uniform movement. The third, was the change effected in the order of battle, which was altered to consist of three instead of four lines.

It was on these foundations that Frederic II. erected a grand superstructure. It was he who, in addition to the practice of these improvements, introduced celerity into the motions of the infantry, and effected an entire change in the charge of the cavalry; before his time the squadrons never advanced with a quicker pace than a trot, and had recourse to fire-arms instead of the sabre. At the action of Sorr, his majesty was saved from destruction by the conduct of his horse; and he is supposed to have gained the battle of Friedburg by the able disposition of his infantry, on which occasion, he, for the first time, developed the system of the oblique line.

The dispute that arose out of the succession of Bavaria was too short to produce any grand changes, although the king of Prussia and prince Henry on the one hand, and the emperor Joseph and marshal Laudohn on the other, were in the field. The war was confined entirely to manœuvres, to marches, and countermarches, and ended without a battle.

The American contest produced a grand change in military tactics, the introduction of the tiralleurs or rifle-men. It is remarkable for the singular circumstance of the English gaining every general action, without being able to achieve a permanent conquest. But no sooner did the war arising out of the French revolution take place, than great and important changes were produced. At the battle of Jemappe, Dumourier introduced an immense number of heavy cannon, and a flying artillery was soon after brought into the field by his countrymen, which produced wonderful effects, and has been since imitated by every neighbouring nation. Pichegru and Moreau, in Holland, Germany, and Flanders, distinguished themselves by the quickness of their evolutions, and the successful manner in which they usually terminated their campaigns. Buonaparte, by the rapidity of his movements, and the enthusiasm with which he inspired the soldiers under him, performed wonders in Italy and Germany. To Dessaix, however, he was greatly indebted for the victory at Marengo, and he gained the battle of Austerlitz, partly by becoming the assailant instead of acting on the defensive, partly by the suddenness of his attack, and partly by piercing between the ill-connected columns of the allied army, the movements of which were neither uniform nor simultaneous.

After all, although war as a science has of late years been certainly carried to a great degree of perfection, yet it has varied but little in its principles; on the contrary, the maximum of the art seems now to be, to bring troops to attack with the bayonet, in the same manner as they were accustomed to do with the pike some centuries ago; and the English by their conduct in Flanders, Egypt, and Calabria have proved, that hand to hand they still preserve their antient reputation, and now as of old, are unequalled at a charge.

Meanwhile, military seminaries for the instruction of those destined to become officers have been established, able masters have been also provided, and the arts and sciences connected with war, are now publicly taught. By the institution of the volunteers, the genius of the nation has been also of late years directed in an eminent degree to military affairs; and it seems now to be established as a principle, that an army has become to the full as necessary as a fleet, for the defence of our own islands, as well as the annoyance of the dominions of our enemies.

Before we conclude this subject, it may be necessary to enumerate a few of the general principles, laid down by those who have treated of the art of modern warfare; observing at the same time, that they apply rather to a continent than an island.

1. It is necessary to have magazines for the supply of an army, and fortresses for the protection of these supplies.

2. There should be a range of fortresses on the same line, to serve as a base for future operations.

3. To undertake with safety an offensive operation against the enemy, it is necessary that the two fortresses at the extremities of this line, should be separate at such a distance from each other, that the two lines of operation proceeding from them may meet at the given object, and form an angle of at least 90 degrees.

4. It is easier to stop the progress of an enemy by occupying a frontier on his flank, than in his front.

5. The best way of opposing an offensive operation, is to act offensively.

6. The subsistence of the enemy's army, rather than the army itself, ought to be the chief object against which operations are to be directed.

7. It is always possible to avoid a combat, by preventing the enemy from approaching too near.

8. A general ought never to wait an attack, but to put himself in movement to act offensively, even if in possession of a strong position.

9. An enemy can never be drawn up so as to prevent his flank from being turned.

10. The front opposed to the enemy ought to extend beyond, so as to envelope him, and he may be enveloped by an inferior number, provided it is posted on his flanks.

11. The infantry ought to be constantly supported by the cavalry, and the best way of achieving this, is to draw up the latter in the rear.

12. A column is the best defensive figure that can be assumed against cavalry.

WARS. The following are the most remarkable wars in which this country has been engaged, since the

War with Scotland, 1068.

Peace with { ditto, 1113.
France, 1113.

War with France, 1116.

Peace with { ditto, 1118.
Scotland, 1139.

War with France, 1161.

Peace with ditto, 1186.

War again with France, with success, 1194.

Peace with ditto, 1195.

Civil war { renewed, 1215—ended, 1216.
with France, 1224-ended, 1234.
1262—ended, 1267.

War, civil { with France, 1294.
with Scotland, 1296.

Peace { with France, 1299.
with Scotland, 1323.

War { again with Scotland, 1327.
ended, 1328.
again with Scotland, 1333.
with France, 1339.

Peace with France, May 8, 1360.

War { with France, 1368.
civil, 1400.
with Scotland, 1400.

Peace with France, May 31, 1420.

War { with France, 1422.
civil, between York and Lancaster, 1452.

Peace with France, October 1471.

War { civil, 1486.
with France, Oct. 6, 1492.

Peace { with ditto, Nov. 3, 1492.
with Scotland, 1502.

War { with France, Feb. 4, 1512.
with Scotland, 1513.

Peace with France, Aug. 7, 1514.

War with { ditto, 1522.
Scotland, 1522.

Peace with { France, 1527.
Scotland, 1542.

War with Scotland directly after.

Peace with France and Scotland, June 7, 1546.

War with { Scotland, 1547.
France, 1549.

Peace with both, March 6, 1550.

War { civil, 1553.
with France, June 7, 1557.
with Scotland, 1557.

Peace with { France, April 2, 1559.
Scotland, 1560.

War } with France { 1562.
Peace } 1564.

War with { Scotland, 1570.
Spain, 1588.

Peace with ditto, Aug. 18, 1604.

War with { Spain, 1624.
France, 1627.

Peace with Spain and France, April 14, 1629.

War { civil, 1642.
with the Dutch, 1651.

Peace with ditto, April 5, 1654.

War with Spain, 1655.

Peace with Spain, Sept. 10, 1660.

War with { France, Jan. 26, 1666.
Denmark, Oct. 19, 1666.

Peace with the French, Danes, and Dutch, Aug. 24, 1667.

Peace with Spain, Feb. 13, 1668.

War with the Algerines, Sept. 6, 1669.

Peace with ditto, Nov. 19, 1671.

War with the Dutch, March, 1672.

Peace with ditto, Feb. 28, 1674.

War with France, May 7, 1689.

Peace, general, of Rhyswick, Sep. 20, 1697.

War with France, May 4, 1702.

Peace of Utrecht, March 13, 1713.

War with Spain, Dec. 1718.

Peace with ditto, 1721.

War with { Spain, 1739.
France, March 31, 1744.

War with { France, 1756.
Spain, Jan. 4, 1762.

Peace with France and Spain, Feb. 10, 1763.

War with the Caribbs of St. Vincent in 1773.

War { civil, in America, commenced July 14, 1774.
with France, Feb. 6, 1778.
with Spain, April 17, 1780.
with Holland, 1780.

Peace with { France,
Spain,
Holland,
America, } Sept. 3, 1783.

War with France by the English, Prussians, Austrians, and other German powers, in 1793.

Peace between Prussia and the French Republic, 1795.

Peace between Spain and the French Republic, 1795.

Peace between the French and the Sardinians in 1796.

Peace between the French and the Austrians in 1797.

War between the British and Tippoo Saib in India, in 1797.

War with the French Republic by the Austrians, Russians, Neapolitans, &c. 1798.

War with the Turks, and the invasion of Egypt, in 1798.

Peace between the French and the Russians in 1799.

Peace between the French and Austrians in 1800.

Preliminaries of peace commenced between the French and the Ottoman empire in consequence of the reduction of Egypt by the British forces in 1801.

Preliminaries of peace between France and Great Britain, &c. 1801.

Peace between France and England, 1802.

War with France, 1803.

Wars, *different kinds of.* There are four different kinds of war, each of which is to be conducted differently the one from the other, viz. the offensive; the defensive; that between equal powers; and the auxiliary, which is carried on out of our own territories to succour a prince or ally, or to assist a weaker whom a more powerful prince has attacked.

Offensive war must be long meditated on in private before it is openly entered upon; when the success will depend upon two essential points; that the plan shall be justly formed, and the enterprise conducted with order. It should be well and maturely considered and digested, and with the greatest secrecy; lest, however able the prince or his council may be, some of the precautions necessary to be taken, should be discovered. These precautions are infinite both at home and abroad.

Abroad, they consist in alliances, and security not to be disturbed in the meditated expedition, foreign levies, and the buying up of warlike ammunition, as well to increase your own stores as to prevent the enemy from getting them.

The precautions at home, consist in providing for the security of our distant frontiers, levying new troops, or augmenting the old ones, with as little noise as possible; furnishing your magazines with ammunition; constructing carriages for artillery and provisions; buying up horses, which should be done as much as possible among your neighbours; both to prevent their furnishing the enemy, and to preserve your own for the cavalry and the particular equipages of the officers.

Defensive war may be divided into three kinds. It is either a war sustained by a prince, who is suddenly attacked by another superior to him in troops and in means; or a prince makes this sort of war by choice on one side of his frontiers, while he carries on offensive war elsewhere; or it is a war become defensive by the loss of a battle.

A defensive war which a prince attacked by a superior enemy sustains, depends entirely on the capacity of his general. His particular application should be, to choose advantageous camps to stop the enemy, without however being obliged to fight him; to multiply small advantages; to harass and perplex the enemy in his foraging parties, and to oblige them to do it with great escorts; to attack their convoys; to render the passages of rivers or defiles as difficult to them as possible; to force them to keep together; if they want to attack a town, to throw in succours before it is invested; in short, in the beginning his chief aim should be, to acquire the enemy's respect by his vigilance and activity, and by forcing him to be circumspect in his marches and manner of encampment, to gain time himself, and make the enemy lose it. An able general, carefully pursuing these maxims, will give courage to his soldiers, and to the inhabitants of the country; he gives time to his prince to take proper precautions to resist the enemy who attacks him; and thus changes the nature of this vexatious kind of warfare.

The management of a defensive war requires more military judgment than that of an offensive one.

A war between equal powers, is that in which the neighbouring princes take no part, so long as the belligerent parties obtain no great advantage, the one over the other. This sort of war never should last long if you want to reap any advantages from it. As to its rules, they are entirely conformable to those already given; but we may look on it as a certain maxim in this sort of war, that the general who is the most active and penetrating, will ever in the end prevail over him, who possesses these qualities in a less degree; because, by his activity and penetration, he will multiply small advantages, till at last they procure him a decisive superiority. A general who is continually attentive to procure himself small advantages, ever obtains his end, which is to ruin the enemy's army; in which case he changes the nature of the war, and makes it offensive; which should ever be the chief object of his prince.

Auxiliary war, is that in which a prince succours his neighbours, either in consequence of alliances or engagements entered into with them, or sometimes to prevent their falling under the power of an ambitious prince.

If it is in virtue of treaties, he observes them religiously, in furnishing the number of troops prescribed, and even offering to augment his quota if required; or in making a diversion by attacking the common enemy, or his allies.

If it is to prevent a neighbouring prince from being crushed by a power, who after this conquest may become dangerous to yourself, there are several measures to be taken for your own particular interest. One of the chief is, to exact from those you succour, the possession of some place in security, lest they make their peace without your knowledge, or to your prejudice.

The general, therefore, who is chosen for the command of this auxiliary corps, should have wisdom, penetration, and foresight; wisdom, to preserve a proper discipline in his corps, that the allied prince may have no cause to complain of him; foresight and penetration, to prevent his troops suffering for want of subsistence, or being exposed to the perils of war, but in proportion to their numbers with those of the allied prince; and finally, that nothing shall pass without his knowledge, which may be prejudicial to his master.

War, *council of*, is an assembly of great officers, called by a general, or commander, to deliberate with him on enterprises and attempts to be made. On some occasions, council of war is also understood of an assembly of officers, sitting in judgment on delinquent soldiers, deserters, coward officers, &c.

WARD, in law-books, a word of divers significations; thus, a ward in London, is a part of the city committed to the special charge of one of the aldermen of the city. There are twenty-six wards in London, which are as hundreds, and the parishes thereof as towns. A forest is also divided into wards, and so are most of our hospitals.

WARDEN, one who has the charge or keeping of any person, or thing, by office. Such is the warden of the Fleet, the keeper of the Fleet-prison; who has the charge of the prisoners there, especially such as are committed from the court of chancery for contempt.

Warden, in an university, is the head of a college, answering to what in other colleges we call the master. Warden, or lord-warden of the cinque-ports, is the governor of these noted havens, who has the authority of an admiral, and sends out writs in his own name. Warden of the mint, is an officer whose business it is to receive the gold and silver bullion brought by the merchants to pay them for it, and oversee the other officers. He is called keeper of the exchange and mint.

Warden, *church*. See Church-wardens.

WARDMOTE, in London, is a court so called which is kept in every ward of the city, answering to the curiata comitia in antient Rome.

WARDS, was a court first erected in the reign of Henry VIII, and afterwards augmented by him with the issue of liveries; whence it was styled the court of wards and liveries, but dissolved by 12 Car. II.

WARDSHIP. In our antient customs, when the tenant died, and his heir was under the age of twenty-one being a male, or fourteen being a female, the lord was entitled to the wardship of the heir, and was called the guardian in chivalry. This wardship consisted in having the custody of the body and lands of such heir, without any account of the profits, till the age of twenty-one in males, and fourteen (which was afterwards advanced to sixteen) in females. For the law supposed the heir male unable to perform knight's service till twenty-one; but as for the female, she was supposed capable at fourteen to marry, and then her husband might perform the office. 2 Black. 67. This privilege of the lord's was abolished under the Commonwealth, and the abolition confirmed by stat. 12 C. II. c. 24.

WARNING-WHEEL, in a clock, is the third or fourth, according to its distance from the first wheel. See Clock-work.

WARP, in the manufactures, is the threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and across which the workman by means of his shuttle passes the threads of the woof, to form a cloth, ribband, fustian, or other stuff.

For a woollen stuff to have the necessary qualities, it is required that the threads of the warp should be of the same kind of wool, and of the same fineness, throughout; that they are sized with Flanders or parchment-size, well prepared; and that they should be in sufficient number with regard to the breadth of the stuff to be wrought.

To warp a ship is to shift her from one place to another, when the wind and tide will permit it without danger.

WARRANT, a præcipe under hand and seal to some officer, to bring any offender before the person granting it; and warrants of commitment are issued by the privy council, a secretary of state, or justice of the peace, &c. where there has been a private information, or a witness had deposed against an offender. Wood's Inst. 614.

Any one under the degree of nobility may be arrested for a misdemeanour, or any thing done against the peace of the kingdom, by warrant from a justice of the peace; but if the person is a peer of the realm, he must be apprehended for a breach of the peace by warrant out of B. R. Dalt. Just. 263.

A constable ought not to execute a justice's warrant, where the warrant is unlawful, or the justice has no jurisdiction; if he does he may be punished. Plowd. 394.

But if any person abuses it, by throwing it in the dirt, &c. or refuses to execute a lawful warrant, it is a contempt of the king's process, for which the offender may be indicted and fined. Crompt. 149.

A general warrant to apprehend all persons suspected, without naming or particularly describing any person in special, is illegal and void for its uncertainty; for it is the duty of the magistrate, and ought not to be left to the officer, to judge of the ground of the suspicion. Also a warrant to apprehend all persons guilty of such a crime, is no legal warrant; for the point upon which its authority rests, is a fact to be decided on a subsequent trial; namely, whether the person apprehended thereupon is guilty or not guilty. 4 Black. 291.

A warrant may be lawfully granted by any justice for treason, felony, or præmunire, or any other offence against the peace; and it seems clear, that where a statute gives any one justice a jurisdiction over any offence, or a power to require any person to do a certain thing ordained by such a statute, it impliedly gives a power to every such justice to make out a warrant to bring before him any one accused of such offence, or compelled to do any thing ordained by such statute; for it cannot but be intended, that a statute which gives a person jurisdiction over an offence, means also to give him the power incident to all courts, of compelling the party to come before him. 2 Haw. 84.

But in cases where the king is not a party, or where no corporal punishment is appointed, as in cases for servants' wages and the like, it seems that a summons is the more proper process; and for default of appearance, the justice may proceed; and so indeed it is often directed by special statutes.

A warrant from any of the justices of the court of king's bench extends over all the kingdom, and is tested or dated England; but a warrant of a justice of peace in one county, must be backed, that is, signed, by a justice of another county, before it can be executed there. And a warrant for apprehending an English or a Scotch offender, may be indorsed in the opposite kingdom, and the offender carried back to that part of the united kingdom in which the offence was committed. 4 Black. 291.

WARRANT *of attorney*, is an authority and power given by a client to his attorney, to appear and plead for him; or to suffer judgment to pass against him by confessing the action, by nil dicit, non sum informatus, &c. And although a warrant of attorney given by a man in custody to confess a judgment, no attorney being present, is void as to the entry of judgment; yet it may be a good warrant to appear and file common bail. 2 Lit. Abr. 629.

WARRANTIA CHARTÆ, a writ that lies where a man is enfeoffed of lands with warranty, and then he is sued or impleaded. And if the feoffee is impleaded in assize, or other action, in which he cannot vouch or call to warranty, he shall have this writ against the feoffer, or his heirs, to compel them to warrant the land to him; and if the land is recovered from him, he shall recover as much lands in value against the warrantor, &c.; but the warrantia chartæ ought to be brought by the feoffee, depending the first writ against him, or he has lost his advantage. F. N. B. 134.

WARRANTIA DIEI, a writ lying in cases where a man, having a day assigned personally to appear in court to any action wherein he is sued, is in the mean time employed in the king's service, so that he cannot come at the day assigned. This writ is directed to the justices to this end, that they neither take nor record him in default for that day.

WARRANTY, a promise or covenant by deed, made by the bargainor, for himself and his heirs, to warrant or secure the bargainee and his heirs against all men, for the enjoying any thing agreed on between them.

Warranty is either real or personal; real, when it is annexed to lands or tenements granted for life, &c. And this is either in deed, as by the word warrantizo expressly; or in law, as by the word dedi, or some other amplification. Personal, which either respects the property of the thing sold, or the quality of it. Cowel.

Warranties in their more general divisions are of two kinds; first, a warranty in deed, or an express warranty, which is when a fine, or feoffment in fee, or a lease for life, is made by deed, which has an express clause of warranty contained in it; as when a conusor, feoffor, or lessor, covenants to warrant the land to the conusee, feoffee, or lessee; secondly, a warrant in law, or an implied warranty, which is, when it is not expressed by the party, but tacitly made and implied by the law. 1 Inst. 365.

A warranty in deed is either lineal or collateral. A lineal warranty is a covenant real, annexed to the land by him, who either was owner of or might have inherited the land, and from whom his heir lineal or collateral, might possibly have claimed the land as heir from him that made the warranty. A collateral warranty is made by him that had no right, or possibility of right, to the land, and is collateral to the title of the land. 1 Inst. 370.

WARREN, is a franchise or place privileged, by prescription or grant from the king, for the keeping of beasts and fowls of the warren; which are coneys, partridges, pheasants, and some add quails, woodcocks, and water-fowl. 1 Inst. 233.

These were looked upon as royal game, and the franchise of free warren was invented to protect them, by giving the grantee a sole and exclusive power of killing such game, so far as his warren extended, on condition of his preventing other persons; for, by the common law, no man, not even a lord of a manor, could justify killing game on another man's soil, unless he had the liberty of free warren. 2 Black. 39.

WARREN, *rabbit*. In setting up a warren, great caution is to be used for the fixing upon a proper place, and a right situation. It should always be upon a small ascent, and exposed to the east or the south. The soil that is most suitable, is that which is sandy; for when the soil is clayey or tough, the rabbits find greater difficulty in making their burrows, and never do it so well; and if the soil is boggy or moorish, there would be very little advantage from the warren, for wet is very destructive of these animals.

All due precautions must be taken, that the warren may be so contrived, that the rabbits may habituate themselves to it with ease. Many would have it that warrens should be enclosed with walls; but this a very expensive method, and seems not necessary or advisable; for we find but very few that are so, and those do not succeed at all the better for it.

WART. See SURGERY.

WASH, among distillers, the fermentable liquor used by the malt-distillers. See DISTILLATION.

WASHING, *in design*. See WATER-COLOURS.

WASP. See VESPA.

WASTE, is the committing any spoil or destruction in houses, lands, &c. by tenants, to the damage of the heir, or of him in reversion or remainder; whereupon the writ or action of waste, is brought for the recovery of the thing wasted, and damages for the waste done. 5 Bac. Abr. 459.

There are two kinds of waste, voluntary or actual, and negligent or permissive. Voluntary waste may be done by pulling down or prostrating houses, or cutting down timber trees; negligent waste may be, by suffering a house to be uncovered, by which the spars or rafters, planches, or other timber of the house, are rotten. 1 Inst. 53.

A writ of waste, to punish the offence after it has been committed, is an action partly founded upon the common law, and partly upon the statute of Gloucester; and may be brought by him that has the immediate estate of inheritance in reversion or remainder, against the tenant for life, tenant in dower, tenant by the courtesy, or tenant for years. 3 Black. 227.

This action of waste is a mixed action; partly real, so far as it recovers land, and partly personal, so far as it recovers damages: for it is brought for both those purposes; and if the waste is proved, the plaintiff shall recover the thing or place wasted, and also treble damages by the said statute. 6 Ed. I. c. 5.

The writ of waste, calls upon the tenant to appear and shew cause why he has committed waste and destruction in the place named, to the dishersion of the plaintiff. And if the defendant makes default, or does not appear at the day assigned him, then the sheriff is to take with him a jury of twelve men, and go in person to the place alleged to be wasted, and there enquire of the waste done, and the damages; and make a return or report of the same to the court, upon which report the judgment is founded. 3 Black. 228.

WASTE *of the forest*, is properly where a man cuts down his own woods within the forest, without licence of the king or lord chief justice in eyre.

WASTE is also taken for those lands which are not in any man's occupation, but lie common.

They seem to be so called, because the lord cannot make such profit of them as of his other lands, by reason of the use others have thereof, for passing to and fro. Upon this none may build, cut down trees, dig, &c. without the lord's licence.

WATCH, in the art of war, a number of men posted at any passage, or a company of the guards who go on the patrole. At sea, the term watch denotes a measure or space of four hours, because half the ship's company watch and do duty in their turns, so long at a time; and they are termed starboard watch, and larboard watch.

WATCH AND WARD. Watching is properly intended in the night, and warding for the day time. Dalt. 104.

Persons aggrieved by assessments for watch and ward, may appeal to the mayor. 11 G. I. c. 18.

WATCH is also used for a small portable movement or machine for the measuring of time, having its motion regulated by a spiral spring

Watches, strictly taken, are all such movements as shew the parts of time; as clocks are such as publish it, by striking on a bell, &c. But, commonly, the name watch is appropriated to such as are carried in the pocket, and clock to the large movements, whether they strike or not. See CLOCK.

The several members of the watch part are: 1. The balance, consisting of the rim, which is its circular part; and the verge, which is its spindle, to which belong the two pallets or levers that play in the teeth of the crown-wheel. 2. The potence, or pottance, which is the strong stud in pocket-watches, whereon the lower pivot of the verge plays, and in the middle of which one pivot of the balance-wheel plays; the bottom of the potence is called the foot, the middle part the nose, and the upper part the shoulder. 3. The cock, which is the piece covering the balance. 4. The regulator, or pendulum-spring, which is the small spring in new pocket-watches, underneath the balance. 5. The pendulum, whose parts are the verge, pallets, cocks, and the bob. 6. The wheels, which are the crown-wheel in pocket-pieces, and swing-wheel in pendulums, serving to drive the balance or pendulum. 7. The contrate-wheel, which is that next the crown-wheel, &c. and whose teeth and hoop lie contrary to those of other wheels, whence the name. 8. The great or first wheel, which is that the fusee, &c. immediately drives; after which are the second wheel, third wheel, &c. 9. Lastly, between the frame and dial-plate, is the pinion of report, which is that fixed on the arbor of the great wheel, and serves to drive the dial-wheel, as that serves to carry the hand.

Spring or pendulum watches are pretty much upon the same principle with pendulum clocks, whence their denomination. If a pendulum describing little arches of a circle makes vibrations of unequal lengths in equal times, it is because it describes the greater with a greater velocity. For the same reason a spring put in motion, and making greater or less vibrations, as it is more or less stiff, and as it has a greater or less degree of motion given it, performs them nearly in equal times. Hence, as the vibrations of the pendulum had been applied to large clocks, to rectify the inequality of their motions, so to correct the unequal motions of the balance of watches, a spring is added, by the isochronism of whose vibrations the correction is to be effected.

The spring is usually wound into a spiral, that, in the little compass allotted it, it may be as long as possible, and may have strength enough not to be mastered and dragged about by the inequalities of the balance it is to regulate. The vibrations of the two parts, viz. the spring and balance, should be of some length, only so adjusted as that the spring, being more regular in the length of its vibrations than the balance, may on occasion communicate its regularity thereto.

The invention of spring or pocket watches is owing to the artists of the present age. It is true, we find mention made of a watch presented to Charles V. in the history of that prince; but this in all probability was no more than a kind of clock to be set on a table, some resemblance whereof we have still remaining in the antient pieces made before the year 1670.

In effect, it is between Dr. Hooke and Mr. Huygens, that the glory of this excellent invention lies, but to which of them it properly belongs, is greatly disputed; the English ascribing it to the former, and the French, Dutch, &c. to the latter. Mr. Derham, in his Artificial Clock-maker, says plainly that Dr. Hooke was the inventor; and adds, that he contrived various ways of regulation. One way was with a loadstone. Another with a tender straight spring, one end whereof played backwards and forwards with the balance, so that the balance was to the spring as the bob to a pendulum, and the spring as the rod of it. A third method was with two balances, of which there were divers sorts, some having a spiral spring to the balance for a regulator, and others without. But the way that prevailed and continues in mode, was with one balance, and one spring running round the upper part of the verge; though this has a disadvantage which those of two springs, &c. were free from, in that a sudden jerk or confused shake will alter its vibrations, and put it in an unusual hurry.

We shall conclude this article with an account of the mechanism of a common pocket-watch.

The Plate Watch-work, explains the construction of a common pocket-watch. The moving power is a spiral steel spring (fig. 3), which is coiled up close by a tool used for the purpose, and put into a brass box (fig. 2) called the barrel: the spring has a hook at its outer end which is put through a hole in the side of the barrel and riveted; the inner end has an oblong opening cut through it, to receive a hook upon the barrel arbor (fig. 6); this arbor goes through the bottom of the barrel, and is square to hold a worm-wheel *d*, (fig. 5) which is turned round by a worm *b*; the ends of the arbor project below this, and it is pivoted into the lower plate A (fig. 8) of the watch: the top of the barrel has a cover put over it, through which the pivot of the arbor projects, and works in a socket in the upper plate D.

The barrel thus mounted has a steel chain *a*, (figs. 1 and 8) hooked to its upper end, and coiled round it; the other end of this chain is hooked to the lower part of the fusee E (figs. 1 and 8). It is evident that when the fusee is turned by the watch-key, it will wind the chain off the barrel on itself; and as one end of the spring is fastened to the barrel, and the other is hooked to the arbor (which is prevented from turning by the worm-wheel beneath), the spring will be coiled up into a smaller compass than it was before, and by its re-action will, when the watch-key is taken off, turn the fusee and keep the watch going. The fusee has a spiral groove cut round it, as shewn in fig. 4, in which the chain lies: this groove is cut by an engine, so that the chain shall pull from the smallest part of the fusee, when the spring is wound up, and act with its greatest force; and gradually increases in size as the spring unwinds and acts with less power, so that the effect upon the great wheel *e* (figs. 1, 8, and 7) may be always the same, and cause the watch to go with regularity; and this effect can be at any time increased or diminished by turning the worm *b*, (fig. 5) which coils the spring up closer, and causes it to act with greater force, or vice versa.

The fusee (fig. 4) has a ratchet wheel, at its lower end, which takes into a click fixed in a hollow cut in the great wheel (fig. 7), in order that when the watch is winding up, the fusee may slip round without the great wheel; and that when the spring draws it round in the other direction, it may move the great wheel with it, and the other wheels of the watch. The great wheel *e*, has 48 teeth on its circumference, which take into and turn a pinion of 12 teeth, fixed on the same arbor with the centre wheel *g*, and fig. 9, which has 54 teeth to turn a pinion of six leaves on the arbor of the third wheel *h*, and fig. 10; the third wheel has 48 teeth, and turns a pinion of six on the arbor of the contrate wheel *i*, and fig. 11, which has 48 teeth cut parallel to its axis, by which it turns a pinion of six leaves, fixed to the balance-wheel *k*, fig. 8, 12, and 14. The pivots of the arbor of this wheel turn, one in a frame F, (fig. 8, and fig. 15) called the pottance, fixed to the upper plate; and the other in a small piece fixed to the upper part, called the counter-pottance, so that when the two plates are put together, the balance-wheel pinion may work into the teeth of the contrate weel. The balance wheel has 15 teeth, by which it impels the balance *l*, (figs. 8 and 16, and fig. 13); the arbor of the balance, which is called the verge, has two pallets projecting from it nearly at right angles to each other; these are acted upon by the balance wheel, as shewn in fig. 14, where the lower pallet is supposed to be in contact with one of the teeth of the balance wheel, which, as it turns round, pushes the pallet round and the balance with it, till the balance has made about a quarter of a turn: the tooth of the balance wheel then slips off and escapes; in this position the watch would run down if it were not for the upper pallet at that instant taking another tooth on the opposite side of the balance wheel, which, as it moves in a contrary direction, pushes the balance back again, till the tooth escapes the pallet; the lower pallet then engages the wheel as before. But for the better regulation of the time, the balance has a very fine spring *m* (fig. 16), called the pendulum spring, with the inner end fixed to the verge just beneath the balance, and the outer end pinned to a stud fixed to the top of the upper plate of the watch, so that the balance will rest only in one position, and if it is moved either way by the balance wheel, the spring will have a tendency to bring it to the same position again. When the lower pallet, for instance, has just liberated a tooth of the balance wheel, the pendulum spring is strained, and returns the balance to its point of rest instantaneously, the balance wheel following the upper pallet by the action of the main spring; and when the balance wheel comes to push the balance beyond its point of rest the other way, it moves slowly, because it has the elasticity of the pendulum spring to overcome.

It is evident that by strengthening or weakening this spring, the velocity of the balance can be regulated, which is done by a contrivance shewn in fig. 16, and the under side of it in fig. 17. It is a plate of brass screwed to the top of the upper plate, close under the balance; and at one place it is hollowed out to receive a wheel *n*, of 20 teeth, which turns a segment of a wheel *p*, called the curb, which moves round in a circular groove: it has a projecting leaf *q*, with a notch in it to receive the pendulum spring; so that by turning the wheel with a key put on a square part of its arbor, the spring is lengthened or shortened, so as to give it a different power, and make the balance vibrate quicker or slower; the arbor of the wheel *n*, has a dial *r*, (fig. 16) upon it, with divisions to set it by. The upper pivot of the verge runs in a cock screwed to the upper plate, as shewn in fig. 8, which covers the balance and protects it from violence; and the lower pivot works in the bottom of the pottance; the socket for the pivot of the balance wheel is made in a small piece of brass, which slides in a groove made in the pottance, as shewn in fig. 15, so that by drawing the slide in or out, the teeth of the balance wheel shall just clear one pallet before it takes the other.

The watch is so adjusted by the pendulum spring, that the balance shall vibrate so as to turn the centre wheel round once in an hour: the spindle of this projects through the lower plate (fig. 8), and has a tube fitted on it, which is square at the top, and carries the minute hand; the other end of this tube has a pinion of 12 teeth on it, which turns the minute wheel *s*, (figs. 8 and 18) of 48, and its pinion of 16, which moves the hour wheel *t*, of 48 teeth: the spindle of this is a tube which is put over the tube of the minute hand, and has the hour hand fixed on it to indicate the time upon the dial-plate.

WATCH, *striking*, one which, besides the common watch-work for measuring time, has a clock part for striking the hours, so that, properly speaking, they are pocket-clocks. See CLOCK.

WATCH, *repeating*, one that by only pulling a string, pushing in a pin, &c. repeats the hour, quarter, or minute, at any time of the day or night.

Watches made by artificers are to have the makers' names, under the penalty of 20*l*. 9 and 10 W. III. c. 28.

WATCHING. See MEDICINE.

WATER was universally considered as a simple elementary substance, till the chemists of the present age proved, by experiments, the substance of which has been stated in a preceding article (see CHEMISTRY), that it is in reality a compound body. Its principles have been ascertained both by composition and decomposition; and one hundred parts of water are found to consist of eighty-five parts of oxygen, and fifteen of hydrogen, with a certain portion of caloric.

This very useful and necessary fluid presents itself to our notice in three distinct forms, namely, in its liquid state, in the state of vapour or steam, and, lastly, in its frozen state. See FREEZING, EVAPORATION, STEAM, &c.

Water, when fluid, is not in its most simple state; for its fluidity depends on a certain quantity of caloric, which enters into combination with it, and insinuating itself between the particles of the water, renders them capable of moving in all directions.

We are supplied with water either from the atmosphere, whence it descends in the form of rain, hail, or snow, or from the earth, which sends it forth in springs and rivulets. In the former case, the watery exhalations drawn from the sea, and the surface of the earth by the sun's heat, form clouds, whose particles being afterwards condensed, fall back again in showers. In the latter, the water which falls on the tops of mountains, and other lofty situations, penetrates the earth, and, after passing downwards, breaks forth at some fissure or aperture at a distance from its source.

WATER, *common*. Good water is as transparent as crystal, and entirely colourless. It has no smell, and scarcely any taste; and in general the lighter it is, so much the better. If we compare the different waters which are used for the common purposes of life with each other, and judge of them by the above standard, we shall find them to differ considerably from each other, according to the circumstances of their situation. These waters may be reduced under four heads, namely, 1. Rain water; 2. Spring and river water; 3. Well water; 4. Lake water.

1. Rain water, unless when near a town, or when collected at the commencement of the rain, possesses the properties of good water in perfection, and is as free from foreign ingredients as any native water whatever. The substances which it holds in solution are air, carbonic acid, carbonat of lime, and, according to Bergman, it yields some traces of nitric acid, and a little muriat of lime. The quantity of air in good water does not exceed $\frac{1}{28}$th of the bulk. One hundred cubic inches of water contain generally about one cubic inch of carbonic acid gas. It is to the presence of these two elastic fluids that water owes its taste, and many of the good effects which it produces on animals and vegetables. Hence the vapidness of newly-boiled water from which these gases are expelled. Snow water, when newly melted, is also destitute of gaseous bodies. Hence the reason that fish cannot live in it, as Carradori has ascertained. Hassenfratz, indeed, has endeavoured to prove, that snow water holds oxygen gas in solution; but in all probability the water which he examined had absorbed air from the atmosphere.

The quantity of muriat of lime contained in rain water must be exceedingly minute; as Morveau has ascertained that rain water may be rendered sufficiently pure for chemical purposes by dropping into it a little barytic water, and then exposing it for some time to the atmosphere, and allowing the precipitate formed to deposit. According to that very accurate philosopher, the rain water which drops from the roofs of houses, after it has rained for some time, contains only a little sulphat of lime, which it has dissolved as it trickled over the slates.

2. The water of springs is nothing else than rain water, which, gradually filtring through the earth, collects at the bottom of declivities, and makes its way to the surface. It is therefore equally pure with rain water, provided it does not meet with some soluble body or other in its passage through the soil. But as this is almost always the case, we generally find, even in the purest spring water, a little carbonat of lime and common salt, besides the usual proportion of air and carbonic acid gas. Sometimes also it contains muriat of lime or a little carbonat of soda. Bergman found the springs about Upsal, which are reckoned exceedingly pure, to contain the following foreign bodies:

1. Oxygen gas,	5. Common salt,
2. Carbonic acid,	6. Sulphat of potass,
3. Carbonat of lime,	7. Carbonat of soda,
4. Silica,	8. Muriat of lime.

The whole of these ingredients amounted at an average to 0.00004 parts; and the proportion of each of the solid bodies was as follows:

Carbonat of lime	5.0	Muriat of lime	0.5
Common salt	3.0	Sulphat of potass	0.25
Silica - -	0.5	Carbonat of soda	0.25

River waters may be considered as merely a collection of spring and rain water, and therefore are usually possessed of a degree of purity at least equal to these. Indeed, when their motion is rapid, and their bed siliceous sand, they are generally purer than spring water; depositing during their motion every thing which was merely mechanically suspended, and retaining nothing more than the usual proportion of air and carbonic acid gas, and a very minute quantity of carbonated lime and common salt. When their bed is clayey, they are usually opal-coloured, in consequence of the particles of clay which they hold in suspension.

3. By well water is meant the water which is obtained by digging deep pits, which is not in sufficient quantity to overflow the mouth of the well, but which may be obtained in abundance by pumping. It is essentially the same with spring water, being derived from the very same source; but it is more liable to be impregnated with foreign bodies from the soil, in consequence of its stagnation or slow filtration. Hence the reason that well water is often of that kind which is distinguished by the name of hard water, because it does not dissolve soap, and cannot be used for dressing several kinds of food. These properties are owing to the great proportion of earthy salts which it holds in solution. The most common of these salts is sulphat of lime. These earthy salts have the property of decomposing common soap: their acid unites with the alkali of the soap, while the earthy basis forms with the oil a soap not soluble in water, which envelopes the soap and gives it a greasy feel. These waters may be in general cured by dropping into them an alkaline carbonat. Mr. Sennebier has shewn that well water usually contains a greater proportion of carbonic acid gas than spring or river water.

4. The water of lakes is merely a collection of rain water, spring water, and river water, and of course contains precisely the same heterogeneous salts: but it is seldom so transparent as river water, being usually contaminated with the remains of animal and vegetable bodies which have undergone putrefaction in it. For as lake water is often nearly stagnant, it does not oppose the putrefaction of these bodies, but rather promotes it; whereas in river water, which is constantly in motion, no putrefaction takes place. Hence the reason of the slimy appearance and the brownish colour which often distinguish lake water.

Marsh water contains a still greater proportion of animal and vegetable remains than lake water, because it is altogether stagnant. Moss water is strongly impregnated with those vegetable bodies which constitute mosses, and usually also contains iron.

WATERS, *mineral*. All waters which are distinguished from common water by a peculiar smell, taste, colour, &c. and which in consequence of these properties cannot be applied to the purposes of domestic economy, have been distinguished by the appellation of mineral waters. These occur more or less frequently in different parts of the earth, constituting wells, springs, or fountains; sometimes of the temperature of the soil through which they pass, sometimes warm, and in some cases even at the boiling temperature. Many of these mineral springs attracted the attention of mankind in the earliest ages, and were resorted to by those who laboured under diseases, and employed by them either externally or internally as a medicine. But it was not till towards the end of the 17th century that any attempt was made to detect the ingredients of which these waters were composed, or to discover the substances to which they owed their properties.

The substances hitherto found in mineral waters amount to about 38, and may be reduced under the four following heads: 1. Air and its component parts, oxygen and azotic gas. 2. Acids. 3. Alkalies and earths. 4. Salts.

I. 1. Air is contained in by far the greater number of mineral waters: its proportion does not exceed 1-28th of the bulk of the water. 2. Oxygen gas was first detected in waters by Scheele. Its quantity is usually inconsiderable; and it is incompatible with the presence of sulphureted hydrogen gas or iron. 3. Azotic gas was first detected in Buxton water by Dr. Pearson. Afterwards it was discovered in Harrowgate waters by Dr. Garnet, and in those of Lemington Priors by Mr. Lambe.

II. The only acids hitherto found in waters, except in combination with a base, are the four following: carbonic, sulphurous, boracic, and sulphureted hydrogen gas. 1. Carbonic acid was first discovered in Pyrmont water by Dr. Brownrigg. It is the most common ingredient in mineral waters, 100 cubic inches of the water generally containing from six to 40 cubic inches of this acid gas. According to Westrum, 100 cubic inches of Pyrmont water contain 187 cubic inches of it, or almost double its own bulk. 2. Sulphurous acid has been observed in several of the hot mineral waters in Italy, which are in the neighbourhood of volcanoes. 3. The boracic acid has also been observed in some lakes in Italy. 4. Sulphureted hydrogen gas constitutes the most conspicuous ingredient in those waters which are distinguished by the name of hepatic or sulphureous.

III. The only alkali which has been observed in mineral waters, uncombined, is soda; and the only earthy bodies are silica and lime. 1. Dr. Black detected soda in the hot minerals of Geyzer and Rykum in Iceland; but in most other cases the soda is combined with carbonic acid. 2. Silica was first observed in waters by Bergman. It was afterwards detected in those of Geyzer and Rykum by Dr. Black, and in those of Carlsbad by Kalproth. Hassenfratz observed it in the waters of Pougues, and Brezé in those of Pu. It has been found also in many other mineral waters. 3. Lime is said to have been found uncombined in some mineral waters; but this has not been proved in a satisfactory manner.

IV. The only salts hitherto found in mineral waters, are the following sulphats, nitrats, muriats, carbonats, and hydrosulphurets:

1. Sulphat of soda
2. . . . . ammonia
3. . . . . lime
4. . . . . magnesia
5. . . . . alumina
6. . . . . iron
7. . . . . copper
8. Nitrat of potass
9. . . . . lime
10. . . . . magnesia
11. Muriat of potass
12. . . . . soda
13. . . . . ammonia
14. . . . . barytes
15. . . . . lime
16. . . . . magnesia
17. . . . . alumina
18. . . . . manganese
19. Carbonat of potass
20. . . . . soda
21. . . . . ammonia
22. . . . . lime
23. . . . . magnesia
24. . . . . alumina
25. . . . . iron
26. Hydrosulphuret of lime
27. . . . . . . potass
28. And likewise borax.

Of these genera the carbonats and muriats occur by far most commonly, and the nitrats most rarely.

1. Sulphat of soda is not uncommon, especially in those mineral waters which are distinguished by the epithet saline. 2. Sulphat of ammonia is found in mineral waters near volcanoes. 3. Sulphat of lime is exceedingly common in water. Its presence seems to have been first detected by Dr. Lister in 1682. 4. Sulphat of magnesia is almost constantly an ingredient in those mineral waters which have purgative properties. It was detected in Epsom waters in 1610, and in 1696 Dr. Grew published a treatise on it. 5. Alum is sometimes found in mineral waters, but it is exceedingly rare. 6. Sulphat of iron occurs sometimes in volcanic mineral waters, and has even been observed in other places. But sulphat of copper is only found in the waters which issue from copper mines. 7. Nitre has been found in some springs in Hungary; but it is exceedingly uncommon. 8. Nitrat of lime was first detected in water by Dr. Home of Edinburgh, in 1756. It is said to occur in some springs in the sandy deserts of Arabia. 9. Nitrat of magnesia is said to have been found in some springs. 10. Muriat of potass is uncommon; but it has lately been discovered in the mineral springs of Uhleaborg in Sweden, by Julin. 11. Muriat of soda is so exceedingly common in mineral waters, that hardly a single spring has been analysed without detecting some of it. Muriat of ammonia is uncommon; but it has been found in some mineral springs in Italy, and in Siberia. 13. Muriat of barytes is still more uncommon; but its presence in mineral waters has been announced by Bergman. 14. Muriats of lime and magnesia are common ingredients. 15. Muriat of alumina has been observed in waters by Dr. Withering; but it is very uncommon. 16. Muriat of manganese was mentioned by Bergman as sometimes occurring in mineral waters. It has lately been detected by Lambe in the waters of Lemington Priors, but in an extremely limited proportion. 17. The presence of carbonat of potass in mineral waters has been mentioned by several chemists: if it does occur, it must be in a very small proportion. 18. But carbonat of soda is, perhaps, the most common ingredient of these liquids, if we except common salt and carbonat of lime. 19. Carbonat of ammonia has been discovered in waters; but it is uncommon. 20. Carbonat of lime is found in almost all waters, and is usually held in solution by an excess of acid. It appears from the different experiments of chemists, as stated by Mr. Kirwan, and especially from those of Berthollet, that water saturated with carbonic acid is capable of holding in solution 0.002 of carbonat of lime. Now water saturated with carbonic acid at the temperature of 50°, contains very nearly 0.002 of its weight of carbonic acid. Hence it follows that carbonic acid, when present in such quantity as to saturate water, is capable of holding its own weight of carbonat of lime in solution. Thus we see that 1000 parts by weight of water, when it contains two parts of carbonic acid, is capable of dissolving two parts of carbonat of lime. When the proportion of water is increased, it is capable of holding the carbonat of lime in solution, even when the proportion of carbonic acid united with it is diminished. Thus 24,000 parts of water are capable of holding two parts of carbonat of lime in solution, even when they contain only one part of carbonic acid. The greater the proportion of water, the smaller a proportion of carbonic acid is necessary to keep the lime in solution; and when the water is increased to a certain proportion, no sensible excess of carbonic acid is necessary. It ought to be remarked also, that water, how small a quantity soever of carbonic acid it contains, is capable of holding carbonat of lime in solution, provided the weight of the carbonic acid present exceeds that of the lime. These observations apply equally to the other earthy carbonats held in solution by mineral waters. 21. Carbonat of magnesia is also very common in mineral waters, and is almost always accompanied by carbonat of lime. 22. Carbonat of alumina is said to have been found in waters; but its presence has not been properly ascertained. 23. But carbonat of iron is by no means uncommon; indeed it forms the most remarkable ingredient in those waters which are distinguished by the epithet of chalybeate. 24. The hydrosulphurets of lime and of soda have been frequently detected in those waters which are called sulphureous or hepatic. 25. Borax exists in some lakes in Persia and Thibet; but the nature of these waters has not been ascertained.

Besides these substances, certain vegetable and animal matters have been occasionally observed in mineral waters. But in most cases these are rather to be considered in the light of accidental mixtures than of real component parts of the waters in which they occur.

From the above enumeration, we are enabled to form a pretty accurate idea of the substances which occur in mineral waters; but this is by no means sufficient to make us acquainted with these liquids. No mineral water contains all of these substances. Seldom are there more than five or six of them present together, and hardly ever do they exceed the number of eight or ten. The proportion too in which they enter into mineral waters is generally small, and in many cases extremely so. Now in order to understand the nature of mineral waters, it is necessary to know the substances which most usually associate together, and the proportion in which they commonly associate. In the greater part of mineral waters there is usually some substance present which, from its greater proportion or its greater activity, stamps, in a manner, the character of the water, and gives it those properties by which it is most readily distinguished. This substance of course claims the greatest attention; while the other bodies which enter in a smaller proportion may vary or even be absent altogether, without producing any sensible change in the nature of the water. This circumstance enables us to divide mineral waters into classes, distinguished by the peculiar substance which predominates in each. Accordingly they have been divided into four classes, namely:

1. Acidulous, 3. Hepatic,
2. Chalybeate, 4. Saline.

1. The acidulous waters contain a considerable proportion of carbonic acid. They are easily distinguished by their acid taste, and by their sparkling like champaign wine when poured into a glass. They contain almost constantly some common salt, and in general also a greater or smaller proportion of the earthy carbonats.

2. The chalybeate waters contain a portion of iron, and are easily distinguished by the property which they have of striking a black with the tincture of nutgalls. The iron is usually held in solution by carbonic acid. It very often happens that this acid is in excess; in which case the waters are not only chalybeate but acidulous. This is the case with the waters of Spa and Pyrmont. In some instances the iron is in the state of a sulphat; but this is uncommon. Waters containing the sulphat of iron may be readily distinguished by the property which they have of continuing to strike a black with tincture of nutgalls even after being boiled and filtred; whereas boiling decomposes the carbonat of iron, and causes its base to precipitate.

3. The hepatic or sulphureous waters are those which contain sulphureted hydrogen gas. These waters are easily distinguished by the odour of sulphureted hydrogen gas which they exhale, and by the property which they have of blackening silver and lead. The nature of the waters belonging to this class long puzzled chemists. Though they often deposit sulphur spontaneously, yet no sulphur could be artificially separated from them. The secret was at last discovered by Bergman. These waters are of two kinds: in the first the sulphureted hydrogen is uncombined; in the second it is united to lime or an alkali. They are frequently also impregnated with carbonic acid, and usually contain some muriats or sulphats.

4. Saline waters are those which contain only salts in solution, without iron or carbonic acid in excess. They may be distinguished into four different orders. The waters belonging to the first order contain salts whose base is lime, and generally either the carbonat or the sulphat. They are known by the name of hard waters, and have but a slight disagreeable taste. The waters belonging to the second order are those in which common salt predominates. They are readily recognized by their salt taste, and like sea water usually contain some magnesian and calcareous salts. The waters of the third order contain sulphat of magnesia. They have a bitter taste and are purgative. Finally, the waters of the fourth order are alkaline, containing carbonat of soda. They are easily distinguished by the property which they have of tinging vegetable blues green.

The following table exhibits a synoptical view of the component parts of a considerable number of mineral waters as analysed by different chemists. See Dr. Saunders's Treatise on the Chemical History and Medical Powers of the most celebrated Mineral Waters.

		Gases. Cubic Inches.				Carbonats of				Muriats of				Sulphats of

One pint of the Bath water contains (according to the laborious and delicate analysis of Mr. Phillips),

Carbonic acid - -	$1\frac{1}{5}$	inch.
Muriat of soda - -	$3\frac{1}{2}$	grains.
Sulphat of soda - -	$3\frac{1}{2}$	do.
Sulphat of lime - -	9	do.
Carbonat of lime - -	$\frac{9}{10}$	do.
Silica - - - -	$\frac{1}{5}$	do.
Oxide of iron - -	$\frac{1}{83}$	do.

Waters, *the method of analysing*. The analysis of waters, or the art of ascertaining the different substances which they hold in solution, and of determining the proportion of these substances, is one of the most difficult things in chemistry. The difficulty arises, not only from the diversity of the bodies which occur in waters, but from the very minute quantities of some of the ingredients. Though many attempts had been made to analyse particular waters, and several of these were remarkably well conducted, no general mode of analysis was known till Bergman published his Treatise on Mineral Waters in 1778. This admirable tract carried the subject all at once to a very high degree of perfection. The Bergmannian method has been followed by succeeding chemists, to whom we are indebted not only for a great number of very accurate analyses of mineral waters, but likewise for several improvements in the mode of conducting the analysis. Mr. Kirwan has in 1799 published an essay on the general analysis of waters, no less valuable than that of Bergman; containing all that has hitherto been done on the subject, and enriched by the numerous experiments of Mr. Kirwan himself, which are equally important and well conducted. Mr. Kirwan has given a new method of analysis, which will probably be adopted hereafter; not only because it is shorter and easier than the Bergmannian, but because it is susceptible of a greater degree of accuracy.

The analysis of waters resolves itself into two different branches: 1. The method of ascertaining all the different bodies contained in the water which we are examining. 2. The method of determining the exact proportion of each of these ingredients.

The different bodies which are dissolved and combined in water, are discovered by the addition of certain substances to the water which is subjected to examination. The consequence of the addition is some change in the appearance of the water; and this change indicates the presence or the absence of the bodies suspected. The substances thus employed are distinguished by the name of tests, and are the instruments by means of which the analysis of water is accomplished. They were first introduced into chemistry by Boyle, and were gradually increased by succeeding chemists; but Bergman was the first who ascertained with precision the degree of confidence which can be placed in the different tests. They still continued rather uncertain and precarious, till Mr. Kirwan shewed how they might be combined and arranged in such a manner as to give certain and precise indications whether or not any particular substance constitutes a component part of water. Let us consider by what means the presence or the absence of all the different substances which occur in waters may be ascertained.

I. The gaseous bodies contained in water are obtained by boiling it in a retort luted to a pneumatic apparatus. The method of separating and examining these different bodies shall be described hereafter.

II. The presence of carbonic acid, not combined with a base, or combined in excess, may be detected by the following tests: 1. Lime-water occasions a precipitate soluble with effervescence in muriatic acid. 2. The infusion of litmus is reddened; but the red colour gradually disappears, and may be again restored by the addition of more of the mineral water. 3. When boiled it loses the property of reddening the infusion of litmus.

III. The mineral acids when present, uncombined in water, give the infusion of litmus a permanent red, even though the water has been boiled. Bergman has shewn that paper, stained with litmus, is reddened when dipt into water containing 1-3521 of sulphuric acid.

IV. Water containing sulphureted hydrogen gas is distinguished by the following properties: 1. It exhales the peculiar odour of sulphureted hydrogen gas. 2. It reddens the infusion of litmus fugaciously. 3. It blackens paper dipt into a solution of lead, and precipitates the nitrat of silver black or brown.

V. Alkalies, and alkaline and earthy carbonats, are distinguished by the following tests: 1. The infusion of turmeric, or paper stained with turmeric, is rendered brown by alkalies, or reddish-brown if the quantity is minute. This change is produced when the soda in water amounts only to 1-2217th part. 2. Paper stained with Brazil wood, or the infusion of Brazil wood, is rendered blue; but this change is produced also by the alkaline and earthy carbonats. Bergman ascertained that water containing 1-9945th part of carbonat of soda renders paper stained with Brazil wood blue. 3. Litmus paper reddened by vinegar is restored to its original blue colour. This change is produced by the alkaline and earthy carbonats also. 4. When these changes are fugacious, we may conclude that the alkali is ammonia.

VI. Fixed alkalies exist in water which occasions a precipitate with muriat of magnesia after being boiled. Volatile alkali may be distinguished by the smell, or it may be obtained in the receiver by distilling a portion of the water gently, and then it may be distinguished by the above tests.

VII. Earthy and metallic carbonats are precipitated by boiling the water containing them; except carbonat of magnesia, which is only precipitated imperfectly.

VIII. Iron is discovered by the following tests: 1. The addition of tincture of nutgalls gives water containing iron a purple or black colour. This test indicates the presence of a very minute portion of iron. If the tincture has no effect upon the water after boiling, though it colours it before, the iron is in the state of a carbonat. The following observations of Westrum on the colours which iron gives to nutgalls, as modified by other bodies, deserve attention:

A violet indicates an alkaline carbonat or earthy salt.

Dark purple indicates other alkaline salts.

Purplish red indicates sulphureted hydrogen gas.

Whitish and then black indicates sulphat of lime.

2. The prussian alkali occasions a blue precipitate in water containing iron. If an alkali is present, the blue precipitate does not appear unless the alkali is saturated with an acid.

IX. Sulphuric acid exists in waters which form a precipitate with the following saline solutions:

1. Muriat, nitrat, or acetat of barytes
2. - - - - - strontian
3. - - - - - lime
4. Nitrat or acetat of lead.

Of these the most powerful by far is muriat of barytes, which is capable of detecting the presence of sulphuric acid uncombined, when it does not exceed the millionth part of the water. Acetat of lead is next in point of power. The muriats are more powerful than the nitrats. The calcareous salts are least powerful. All these tests are capable of indicating a much smaller proportion of uncombined sulphuric acid than when it is combined with a base. To render muriat of barytes a certain test of sulphuric acid, the following precautions must be observed: 1. The muriat must be diluted. 2. The alkalies, or alkaline carbonats, if the water contains any, must be previously saturated with muriatic acid. 3. The precipitate must be insoluble in muriatic acid. 4. If boracic acid is suspected, muriat of strontian must be tried, which is not precipitated by boracic acid. 5. The hydrosulphurets precipitate barytic solutions, but their presence is easily discovered by the smell.

X. Muriatic acid is detected by nitrat of silver, which occasions a white precipitate, or a cloud in water containing an exceedingly minute portion of this acid. To render this test certain, the following precautions are necessary: 1. The alkalies or carbonats must be previously saturated with nitric acid. 2. Sulphuric acid, if any should be present, must be previously removed by means of nitrat of barytes. 3. The precipitate must be insoluble in nitric acid.

XI. Boracic acid is detected by means of acetat of lead, with which it forms a precipitate insoluble in acetic acid. But to render this test certain, the alkalies and earths must be previously saturated with acetic acid, and the sulphuric and muriatic acids removed by means of acetat of strontian and acetat of silver.

XII. Barytes is detected by the insoluble white precipitate which it forms with diluted sulphuric acid.

XIII. Lime is detected by means of oxalic acid, which occasions a white precipitate in water containing a very minute proportion of this earth. To render this test decisive, the following precautions are necessary: 1. The mineral acids, if any should be present, must be previously saturated with an alkali. 2. Barytes, if any is present, must be previously removed by means of sulphuric acid. 3. Oxalic acid precipitates magnesia but very slowly, whereas it precipitates lime instantly.

XIV. Magnesia and alumina. The presence of these earths is ascertained by the following tests: 1. Pure ammonia precipitates them both, and no other earth, provided the carbonic acid has been previously separated by a mineral alkali and boiling. 2. Lime-water precipitates only these two earths, provided the carbonic acid is previously removed, and the sulphuric acid also, by means of nitrat of barytes.

The alumina may be separated from the magnesia after both have been precipitated together, either by boiling the precipitate in pure potass, which dissolves the alumina and leaves the magnesia; or the precipitate may be dissolved in muriatic acid precipitated by an alkaline carbonat, dried in the temperature of one hundred degrees, and then exposed to the action of diluted muriatic acid, which dissolves the magnesia without touching the alumina.

XV. Silica may be ascertained by evaporating a portion of the water to dryness, and redissolving the precipitate in muriatic acid. The silica remains behind undissolved.

Such is the method of detecting the different substances commonly found in waters. But as these different substances are almost always combined together, so as to constitute particular salts, it is not sufficient to know in general what the substances are which are found in the water we are examining; we must know also in what manner they are combined. Thus it is not sufficient to know that lime forms an ingredient in a particular water, we must know also the acid with which it is united. Mr. Kirwan first pointed out how to accomplish this difficult task by means of tests. Let us take a short view of his method.

I. To ascertain the presence of the different sulphats.

The sulphats which occur in water are seven; but one of these, namely, sulphat of copper, is so uncommon, that it may be excluded altogether. The same remark applies to sulphat of ammonia. It is almost unnecessary to observe, that no sulphat need be looked for unless both its acid and base have been previously detected in the water.

1. Sulphat of soda may be detected by the following method: Free the water to be examined of all earthy sulphats by evaporating it to one-half, and adding lime-water as long as any precipitate appears. By this means the earths will be all precipitated except lime, and the only remaining earthy sulphat will be sulphat of lime, which will be separated by evaporating the liquid till it becomes concentrated, and then dropping into it a little alcohol, and after filtration adding a little oxalic acid.

With the water thus purified, mix solution of lime. If a precipitate appears either immediately or on the addition of a little alcohol, it is a proof that sulphat of potass or of soda is present; which of the two, may be determined by mixing some of the purified water with acetat of barytes. Sulphat of barytes precipitates. Filtre and evaporate to dryness. Digest the residuum in alcohol. It will dissolve the alkaline acetat. Evaporate to dryness, and the dry salt will deliquesce if it is acetat of potass, but effloresce if it is acetat of soda.

2. Sulphat of lime may be detected by evaporating the water suspected to contain it to a few ounces. A precipitate appears, which, if it is sulphat of lime, is soluble in 500 parts of water; and the solution affords a precipitate with the muriat of barytes, oxalic acid, carbonat of magnesia, and with alcohol.

3. Alum may be detected by mixing carbonat of lime with the water suspected to contain it. If a precipitate appears it indicates the presence of alum, or at least of su l

phat of alumina; provided the water contains no muriat of barytes or metallic sulphats. The first of these salts is incompatible with alum. The second may be removed by the alkaline prussiats. When a precipitate is produced in water by muriat of lime, carbonat of lime, and muriat of magnesia, we may conclude that it contains alum, or sulphat of alumina.

4. Sulphat of magnesia may be detected by means of hydrosulphuret of strontian, which occasions an immediate precipitate with this salt and with no other; provided the water is previously deprived of alum, if any should be present, by means of carbonat of lime; and provided also that it contains no uncombined acid, nor even carbonic acid.

5. Sulphat of iron is precipitated from water by alcohol, and then it may be easily recognised by its properties.

II. To ascertain the presence of the different muriats.

The muriats found in waters amount to eight or nine, if muriat of iron is included. The most common by far is muriat of soda.

1. Muriat of soda and of potass may be detected by the following method: Separate the sulphuric acid by alcohol and nitrat of barytes. Decompose the earthy nitrats and muriats by adding sulphuric acid. Expel the excess of muriatic and nitric acids by heat. Separate the sulphats thus formed by alcohol and barytes-water. The water thus purified can contain nothing but alkaline nitrats and muriats. If it forms a precipitate with acetat of silver, we may conclude that it contains muriat of soda or of potass. To ascertain which, evaporate the liquid thus precipitated to dryness; dissolve the acetat in alcohol. Evaporate to dryness. The salt will deliquesce if it is acetat of potass, but effloresce if it is acetat of potass.

2. Muriat of barytes may be detected by sulphuric acid, as it is the only barytic salt hitherto found in waters.

3. Muriat of lime may be detected by the following method: Free the water of sulphat of lime and other sulphats, by evaporating it to a few ounces, mixing it with spirit of wine, and adding last of all nitrat of barytes as long as any precipitate appears. Filtre off the water, evaporate to dryness, treat the dry mass with alcohol. Evaporate the alcohol to dryness, and dissolve the residuum in water. If this solution gives a precipitate with acetat of silver and oxalic acid, it may contain muriat of lime. It must contain it in that case, if, after being treated with carbonat of lime, it gives no precipitate with ammonia. If it does, separate the lime by means of oxalic acid, filtre and distil with a gentle heat. If the liquid in the receiver gives a precipitate with nitrat of silver, muriat of lime existed in the water.

4. Muriat of magnesia may be detected by separating all the sulphuric acid by means of nitrat of barytes. Filtre, evaporate to dryness, and treat the dry mass with alcohol. Evaporate the alcohol solution to dryness, and dissolve the residuum in water. The muriat of magnesia, if the water contained any, will be found in this solution. Let us suppose that, by the tests formerly described, the presence of muriatic acid and of magnesia in this solution has been ascertained. In that case, if carbonat of lime affords no precipitate, and if sulphuric acid and evaporation, together with the addition of a little alcohol, occasion no precipitate, the solution contains only muriat of magnesia. If these tests give precipitates, we must separate the lime which is present by sulphuric acid and spirit of wine, and distil off the acid with which it was combined. Then the magnesia is to be separated by the oxalic acid and alcohol; and the acid with which it was united is to be distilled off. If the liquid in the retort gives a precipitate with nitrat of silver, the water contains muriat of magnesia.

5. Muriat of alumina may be discovered by saturating the water, if it contains an excess of alkali, with nitric acid, and separating the sulphuric acid by means of nitrat of barytes. If the liquid thus purified gives a precipitate with carbonat of lime, it contains muriat of alumina. The muriat of iron or of manganese, if any is present, is also decomposed, and the iron precipitated by this salt. The precipitate may be dissolved in muriatic acid, and the alumina, iron, and manganese, if they are present, may be afterwards separated.

III. To ascertain the presence of the different nitrats. The nitrats but seldom occur in waters; when they do they may be detected by the following rules:

1. Alkaline nitrats may be detected by freeing the water examined from sulphuric acid by means of acetat of barytes, and from muriatic acid by acetat of silver. Evaporate the filtred liquid, and treat the dry mass with alcohol; what the alcohol leaves can consist only of the alkaline nitrats and acetat of lime. Dissolve it in water. If carbonat of magnesia occasions a precipitate, lime is present. Separate the lime by means of carbonat of magnesia. Filtre and evaporate to dryness, and treat the dried mass with alcohol. The alcohol now leaves only the alkaline nitrats, which may be easily recognised, and distinguished by their respective properties.

2. Nitrat of lime. To detect this salt, concentrate the water, and mix with it alcohol to separate the sulphats. Filtre and distil off the alcohol; then separate the muriatic acid by acetat of silver. Filtre, evaporate to dryness, and dissolve the residuum in alcohol. Evaporate to dryness, and dissolve the dry mass in water. If this solution indicates the presence of lime by the usual tests, the water contained nitrat of lime.

3. To detect nitrat of magnesia, the water is to be freed from sulphats and muriats exactly as described in the last paragraph. The liquid thus purified is to be evaporated to dryness, and the residuum treated with alcohol. The alcohol solution is to be evaporated to dryness, and the dry mass dissolved in water. To this solution potass is to be added as long as any precipitate appears. The solution, filtred, and again evaporated to dryness, is to be treated with alcohol. If it leaves a residuum consisting of nitre (the only residuum which it can leave), the water contained nitrat of magnesia.

Such are the methods by which the presence of the different saline contents of waters may be ascertained. The labour of analysis may be considerably shortened, by observing that the following salts are incompatible with each other, and cannot exist together in water except in very minute proportions:

Salts.	Incompatible with
1. Fixed alkaline sulphats.	Nitrats of lime and magnesia, Muriats of lime and magnesia.
2. Sulphat of lime.	Alkalies, Carbonat of magnesia, Muriat of barytes.
3. Alum.	Alkalies, Muriat of barytes, Nitrat, muriat, carbonat of lime, Carbonat of magnesia.
4. Sulphat of magnesia.	Alkalies, Muriat of barytes. Nitrat and muriat of lime.
5. Sulphat of iron.	Alkalies, Muriat of barytes, Earthy carbonats.
6. Muriat of barytes.	Sulphats, Alkaline carbonats, Earthy carbonats.
7. Muriat of lime.	Sulphats, except of lime, Alkaline carbonats, Carbonat of magnesia.
8. Muriat of magnesia.	Alkaline carbonats, Alkaline carbonats,
9. Nitrat of lime.	Alkaline sulphats, Carbonat of magnesia and alumina, Sulphats, except of lime.

Besides the substances above described, there is sometimes found in water a quantity of bitumen combined with alkali, and in the state of soap. In such waters acids occasion a coagulation; and the coagulum collected on a filtre discovers its bituminous nature by its combustibility.

Water also sometimes contains extractive matter; the presence of which may be detected by means of nitrat of silver. The water suspected to contain it must be freed from sulphuric and nitric acid by means of nitrat of lead. After this, if it gives a brown precipitate with nitrat of silver, we may conclude that extractive matter is present.

The proportion of saline ingredients, held in solution by any water, may be in some measure estimated from its specific gravity. The lighter a water is, the less saline matter does it contain; and, on the other hand, the heavier it is, the greater is the proportion of saline contents. Mr. Kirwan has pointed out a very ingenious method of estimating the saline contents of a mineral water whose specific gravity is known; so that the error does not exceed one or two parts in the hundred. The method is this: Subtract the specific gravity of pure water from the specific gravity of the mineral water examined (both expressed in whole numbers), and multiply the remainder by 1.4. The product is the saline contents, in a quantity of the water denoted by the number employed to indicate the specific gravity of distilled water. Thus let the water be of the specific gravity 1.079, or in whole numbers 1079. Then the specific gravity of distilled water will be 1000. And $\overline{1079 - 1000} \times 1.4 = 110.6$ = saline contents in 1000 parts of the water in question; and consequently 11.06 in 100 parts of the same water. This formula will often be of considerable use, as it serves as a kind of standard to which we may compare our analysis. The saline contents indicated by it are supposed to be freed from their water of crystallization; in which state only they ought to be considered, as Mr. Kirwan has very properly observed, when we speak of the saline contents of a mineral water.

Having by this formula ascertained pretty nearly the proportion of saline contents in the water examined, and having by the tests described in the last section, determined the particular substances which exist in it, let us now proceed to ascertain the proportion of each of these ingredients.

I. The different aerial fluids ought to be first separated and estimated. For this purpose a retort ought to be filled two-thirds with the water, and connected with a jar full of mercury, standing over a mercurial trough. Let the water be made to boil for a quarter of an hour. The aerial fluids will pass over into the jar. When the apparatus is cool, the quantity of air expelled from the water may be determined either by bringing the mercury within and without the jar to a level; or if that cannot be done, by reducing the air to the proper density. The air of the retort ought to be carefully subtracted, and the jar must be divided into cubic inches and tenths.

The only gaseous bodies in water are common air, oxygen gas, azotic gas, carbonic acid, sulphureted hydrogen gas, and sulphurous acid. The last two never exist in water together. The presence of either of them must be ascertained previously by the application of the proper tests. If sulphureted hydrogen gas is present, it will be mixed with the air contained in the glass jar, and must be separated before air is examined. For this purpose, the jar must be carried into a tub of warm water, and nitric acid introduced, which will absorb the sulphureted hydrogen. The residuum is then to be again put into a mercurial jar and examined.

If the water contains sulphurous acid, this previous step is not necessary. Introduce into the air a solution of pure potass, and agitate the whole gently. The carbonic acid and sulphurous acid gas will be absorbed, and leave the other gases. Estimate the bulk of this residuum; this, subtracted from the bulk of the whole, will give the bulk of the carbonic acid and sulphurous acids absorbed.

Evaporate the potass slowly nearly to dryness, and leave it exposed to the atmosphere. Sulphat of potass will be formed, which may be separated by dissolving the carbonat of potass by means of diluted muriatic acid and filtring the solution. One hundred grains of sulphat of potass indicate thirty grains of sulphurous acid, or 42.72 cubic inches of that acid in the state of gas. The bulk of sulphurous acid gas ascertained by this method, subtracted from the bulk of the gas absorbed by the potass, gives the bulk of the carbonic acid gas. Now one hundred cubic inches of carbonic acid, at the temperature of 60°, and barometer at 30 inches, weigh 46.393 grains. Hence it is easy to ascertain its weight.

The air which remains after the separation of the carbonic acid gas is to be examined by the different eudiometrical methods.

When a water contains sulphureted hydrogen gas, the bulk of this gas is to be ascertained in the following manner: Fill three-fourths of a jar with the water to be examined, and invert it in a water trough, and introduce a little nitrous gas. This gas, mixing with the air in the upper part of the jar, will form nitrous acid, which will render the water turbid, by decomposing the sulphureted hydrogen and precipitating sulphur. Continue to add nitrous gas at intervals as long as red fumes appear, then turn up the jar and blow out the air. If the hepatic smell continues, repeat this process. The sulphur precipitated indicates the proportion of hepatic gas in the water; one grain of sulphur indicating the presence of 3.33 cubic inches of that gas.

II. After having estimated the gaseous bodies, the next step is to ascertain the proportions of the earthy carbonats. For this purpose it is necessary to deprive the water of its sulphureted hydrogen, if it contains any. This may be done, either by exposing it to the air for a considerable time, or by treating it with litharge. A sufficient quantity of the water thus purified (if necessary) is to be boiled for a quarter of an hour, and filtred when cool. The earthy carbonats remain on the filtre.

The precipitate thus obtained may be carbonat of lime, of magnesia, of iron, of alumina, or even sulphat of lime. Let us suppose all of these substances to be present together. Treat the mixture with diluted muriatic acid, which will dissolve the whole except the alumina and sulphat of lime. Dry this residuum in a red heat, and note the weight. Then boil it in carbonat of soda; saturate the soda with muriatic acid, and boil the mixture for half an hour. Carbonat of lime and alumina precipitate. Dry this precipitate, and treat it with acetic acid. The lime will be dissolved and the alumina will remain. Dry it and weigh it. Its weight subtracted from the original weight gives the proportion of sulphat of lime.

The muriatic solution contains lime, magnesia, and iron. Add ammonia as long as a reddish precipitate appears. The iron and part of the magnesia are thus separated. Dry the precipitate, and expose it to the air for some time in a heat of 200°; then treat it with acetic acid to dissolve the magnesia, which solution is to be added to the muriatic solution. The iron is to be redissolved in muriatic acid, precipitated by an alkaline carbonat, dried, and weighed.

Add sulphuric acid to the muriatic solution as long as any precipitate appears; then heat the solution and concentrate. Heat the sulphat of lime thus obtained to redness, and weigh it. One hundred grains of it are equivalent to 70 of carbonat of lime dried. Precipitate the magnesia by means of carbonat of soda. Dry it and weigh it. But as part remains in solution, evaporate to dryness, and wash the residuum with a sufficient quantity of distilled water to dissolve the muriat of soda and the sulphat of lime, if any should be still present. What remains behind is carbonat of magnesia. Weigh it, and add its weight to the former. The sulphat of lime, if any, must also be separated and weighed.

III. Let us now consider the method of ascertaining the proportion of mineral acids or alkalies, if any should be present uncombined. The acids which may be present, (omitting the gaseous) are the sulphuric, muriatic, and boracic.

1. The proportion of sulphuric acid is easily determined. Saturate it with barytes water, and ignite the precipitate. One hundred grains of sulphat of barytes thus formed indicate 23.5 of real sulphuric acid.

2. Saturate the muriatic acid with barytes-water, and then precipitate the barytes by sulphuric acid. One hundred parts of the ignited precipitate are equivalent to 21 grains of real muriatic acid.

3. Precipitate the boracic acid by means of acetat of lead. Decompose the borat of lead by boiling it in sulphuric acid. Evaporate to dryness. Dissolve the boracic acid in alcohol, and evaporate the solution; the acid left behind may be weighed.

4. To estimate the proportion of alkaline carbonat present in a water containing it, saturate it with sulphuric acid, and note the weight of real acid necessary. Now 100 grains of real sulphuric acid saturate 121.48 potass, and 78.32 soda.

IV. Let us now consider the method of ascertaining the proportion of the different sulphats. These are six in number; the alkaline sulphats, and those of lime, alumina, magnesia, and iron.

1. The alkaline sulphats may be estimated by precipitating their acid by means of nitrat of barytes, having previously freed the water of all other sulphats. For 170 grains of ignited sulphat of barytes indicate 100 grains of dried sulphat of soda; while 136.36 grains of sulphat of barytes indicate 100 of dry sulphat of potass.

2. Sulphat of lime is easily estimated by evaporating the liquid containing it to a few ounces (having previously saturated the earthy carbonats with nitric acid), and precipitating the sulphat of lime by means of weak alcohol. It may be then dried and weighed.

3. The quantity of alum may be estimated by precipitating the alumina by carbonat of lime or of magnesia (if no lime is present in the liquid). Twelve grains of the alumina heated to incandescence indicate one hundred of crystallized alum, or forty-nine of the dried salt.

4. Sulphat of magnesia may be estimated, provided no other sulphat is present, by precipitating the acid by means of a barytic salt, as 100 parts of ignited sulphat of barytes indicate 52.11 of sulphat of magnesia. If sulphat of lime, and no other sulphat accompanying it, this last may be decomposed, and the lime precipitated by carbonat of magnesia. The weight of the lime thus obtained enables us to ascertain the quantity of sulphat of lime contained in the water. The whole sulphuric acid is then to be precipitated by barytes. This gives the quantity of sulphuric acid; and subtracting the portion which belongs to the sulphat of lime, there remains that which was combined with the magnesia, from which the sulphat of magnesia may be easily estimated.

If sulphat of soda is present, no earthy nitrat or muriat can exist. Therefore, if no other earthy sulphat is present, the magnesia may be precipitated by soda, dried, and weighed; 36.68 grains of which indicate 100 grains of dried sulphat of magnesia. The same process succeeds when sulphat of lime accompanies these two sulphats; only in that case the precipitate, which consists both of lime and magnesia, is to be dissolved in sulphuric acid, evaporated to dryness, and is to be treated with twice its weight of cold water; which dissolves the sulphat of magnesia, and leaves the other salt. Let the sulphat of magnesia be evaporated to dryness, exposed to a heat of 400° and weighed. The same process succeeds if alum is present instead of sulphat of lime. The precipitate in that case, previously dried, is to be treated with acetic acid, which dissolves the magnesia and leaves the alumina. The magnesia may be again precipitated, dried, and weighed. If sulphat of iron is present, it may be separated by exposing the water to the air for some days, and mixing with it a portion of alumina. Both the oxide of iron and the sulphat of alumina thus formed, precipitate in the state of an insoluble powder. The sulphat of magnesia may then be estimated by the rules above explained.

5. Sulphat of iron may be estimated by precipitating the iron by means of prussic alkali, having previously determined the weight of the precipitate produced by the prussiat in a solution of a given weight of sulphat of iron in water. If muriat of iron is also present, which is a very rare case, it may be separated by evaporating the water to dryness, treating the residuum with alcohol, which dissolves the muriat, and leaves the sulphat. Or the sulphat may be estimated with great precision by the rules laid down by Mr. Kirwan.

V. Let us now consider the method of estimating the quantity of the different muriats which may exist in waters.

If muriat of potass or of soda, without any other salt, exists in the water, we have only to decompose them by nitrat of silver, and dry the precipitate; for 217.65 of muriat of silver indicate one hundred of muriat of potass, and two hundred and thirty-five of muriat of silver indicate one hundred of common salt.

The same process is to be followed if the alkaline carbonats are present; only these carbonats must be previously saturated with sulphuric acid, and we must precipitate the muriatic acid by means of sulphat of silver instead of nitrat. The presence of sulphat of soda does not injure the success of this process.

If muriat of ammonia accompanies either of the fixed alkaline sulphats without the presence of any other salt, decompose the sal ammoniac by barytes-water, expel the ammonia by boiling, precipitatethe barytes by diluted sulphuric acid, and saturate the muriatic acid with soda. The sulphat of barytes thus precipitated indicates the quantity of muriat of ammonia; one hundred grains of sulphur indicating 49.09 grains of that salt. If sulphats are present in the solution, they ought to be previously separated.

If common salt is accompanied by muriat of lime, muriat of magnesia, muriat of alumina, or muriat of iron, or by all of these together without any other salts, the earths may be precipitated by barytes-water, and redissolved in muriatic acid. They are then to be separated from each other by the rules formerly laid down; and their weight being determined indicates the quantity of every particular earthy muriat contained in the water. For fifty grains of lime indicate one hundred of dried muriat of lime; thirty grains of magnesia indicate one hundred of the muriat of the earth; and 21.8 grains of alumina indicate one hundred of the muriat of alumina. The barytes is to be separated from the solution by sulphuric acid, and the muriatic acid expelled by heat, or saturated with soda; the common salt may then be ascertained by evaporation, subtracting in the last case the proportion of common salt indicated by the known quantity of muriatic acid from which the earths had been separated.

When sulphats and muriats exist together, they ought to be separated either by precipitating the sulphats by means of alcohol, or by evaporating the whole to dryness, and dissolving the earthy muriats in alcohol. The salts thus separated may be estimated by the rules already laid down.

When alkaline and earthy muriats and sulphat of lime occur together, this last salt is to be decomposed by means of muriat of barytes. The precipitate ascertains the weight of sulphat of lime contained in the water. The estimation is then to be conducted as when nothing but muriats are present; only from the muriat of lime that proportion of muriat must be deducted which is known to have been formed by the infusion of the muriat of barytes.

When muriats of soda, magnesia, and alumina, are present together with sulphats of lime and magnesia, the water to be examined ought to be divided into two equal portions. To the one portion add carbonat of magnesia till the whole of the lime and alumina is precipitated. Ascertain the quautity of lime which gives the proportion of sulphat of lime. Precipitate the sulphuric acid by muriat of barytes. This gives the quantity contained in the sulphat of magnesia and sulphat of lime; subtracting this last portion, we have the quantity of sulphat of magnesia.

From the second portion of water precipitate all the magnesia and alumina by means of lime-water. The weight of these earths enables us to ascertain the weight of muriat of magnesia and of alumina contained in the water, subtracting that part of the magnesia which existed in the state of sulphat, as indicated by the examination of the first portion of water. After this estimation precipitate the sulphuric acid by barytes water, and the lime by carbonic acid. The liquid evaporated to dryness leaves the common salt.

VI. It now only remains to explain the method of ascertaining the proportion of the nitrats which may exist in waters.

1. When nitre accompanies sulphats and muriats without any other nitrat, the sulphats are to be decomposed by acetat of barytes, and the muriats by acetat of silver. The water after filtration, is to be evaporated to dryness, and the residuum treated with alcohol, which dissolves the acetats, and leaves the nitre; the quantity of which may be easily estimated. If an alkali is present, it ought to be previously saturated with sulphuric or muriatic acid.

2. If nitre, common salt, nitrat of lime, and muriat of lime or of magnesia, are present together, the water ought to be evaporated to dryness, and the dry mass treated with alcohol, which takes up the earthy salts. From the residuum, redissolved in water, the nitre may be separated, as estimated as in the last case. The alcohol solution is to be evaporated to dryness, and the residuum redissolved in water. Let us suppose it to contain muriat of magnesia, nitrat of lime, and muriat of lime. Precipitate the muriatic acid by nitrat of silver, which gives the proportion of muriat of magnesia and of lime. Separate the magnesia by means of carbonat of lime, and note its quantity. This gives us the quantity of muriat of magnesia. And subtracting the muriatic acid contained in that salt from the whole acid indicated by the precipitate of silver, we have the proportion of muriat of lime. Lastly, saturate the lime added to precipitate the magnesia with nitric acid. Then precipitate the whole of the lime by sulphuric acid; and subtracting from the whole of the sulphat thus formed that portion formed by the carbonat of lime added, and by the lime contained in the muriat, the residuum gives us the lime contained in the original nitrat; and 35 grains of lime form 100 of dry nitrat of lime.

Water-sea. See Sea.

WATER-COLOURS. Painting in water-colours, is an art capable of affording the highest delight to the eye, since no mode of representation can display the appearances of nature with greater splendour. It is an art which has of late been carried forward with unprecedented success, and may be said at present to be the most perfect species of design or painting, which is in practice amongst our artists. To this the facility of the materials employed in it, contributes in no small degree. It is not attended with the embarrassments to which oil-painting, or most other kinds of painting, are liable, but proceeds by ready and uninterrupted. progress to the completion of its task.

Ths preliminary parts of study requisite for the young student in the attainment of this art, have been treated at large under the article of drawing. See Drawing. We can recommend no more advantageous method for his farther progress, than the carefully studying and copying the various works of excellence by the hands of the best masters, until he shall be able to follow, if not to rival them, in the imitation of nature. We shall now endeavour to furnish him with the best means for this purpose, by describing the colours which are employed in washing, and by giving the most approved directions for preparing and using them.

The materials and implements necessary for the practice of water-colours (or washing, as it is sometimes called) are,—gum-colours, of which we shall treat hereafter more particularly; camels'-hair pencils, fitches, a pallette, and penknife.

The general or simple colours, and the various species of each, fit for painting in water-colours, are as follow:

Whites.	*Browns.*
Ceruse	Spanish brown
Constant white	Spanish liquorice
White lead	Umber
Spanish white	Bistre
Flake white	Burnt Terra de Sienna
Spodium	Unburnt ditto

Blacks.	*Reds.*
Burnt cherry-stones	Native cinnabar
Ivory-black	Burnt ochre
Keating's black	Indian red
Lamp-black	Red lead
Greens.	Minium
Green bice	Lake
Green verditer	Vermilion
Grass-green	Carmine
Sap-green	Red ink
Verdigrise distilled	Indian lake
Blues.	*Yellows.*
Sanders blue	English ochre
Terre-blue	Gall-stone
Blue verditer	Gamboge
Indigo	Masticot
Litmus	Ochre de luce
Smalt	Orpiment
Prussian blue	Roman ochre
Light ditto	Dutch pink
Ultramarine	Saffron-water
Ultramarine ashes	King's yellow
Blue bice	Gold yellow
	French berries.

Directions for preparing the following single colours.

Whites. The best white for painting in water-colours is flake-white; some recommend a white made of pearl and oyster-shells, brought to an impalpable powder, called a pearl-white, which will mix well with any colour. If you use white lead, clarify it with white-wine vinegar; after the white is settled, pour off the vinegar, and wash it with water thus: Put the powder into a glass of water, stir it, and presently pour the water off, while it is white, into another clean glass; when it is settled, pour off the water, and you will have an excellent white; to which add as much gum as is necessary, to give it a gloss.

It has been often noticed, that white lead will turn black, if mixed with water that comes from iron or clay; so that, in the space of a month or two, you may perceive it; and it will also change any colour with which it is mixed.

Some therefore recommend the powder of egg-shells, of the brightest and whitest sort, well ground with gum-water, to the state of an impalpable powder, to which they add one-twentieth part of white sugar-candy; others esteem it most when clarified in spirit of wine, and then use it with gum-water.

It has been found, by repeated experience, that this egg-shell powder is extremely serviceable as a white, in water-colours; and that this, and the oyster-shell powder, rectified and well bruised, will make an excellent mixture with other colours, to keep them from changing.

A fine white, for water-colours, may be made by dissolving filings of silver, or silver-leaf, in aqua-fortis, evaporating the aqua-fortis till it appears like crystal in the bottom of the glass; decant the other part of the aqua-fortis, and wash the silver four or five times in pure water, till it is entirely cleaned from the aqua-fortis, drying it for use. It must be used with the waters of gum and sugar-candy.

A good white for water-colours, proper for miniature, is made thus: Take a pound of the shreddings of glove-leather, and steep them in water; boil them with twelve quarts of water, till it wastes to two; strain it through a linen cloth, into a well-glazed earthen pan; this is called glue or size, and proper to use with colours in candle-light pieces; to know if this is strong enough, try if it is stiff, and firm under your hand.

The glue being melted, reduce some white chalk to a powder, and while it is hot, add such a quantity of the chalk as will bring it to the consistency of a paste, letting it steep for a quarter of an hour; stir it with a brush made of hog's bristles.

In order to make this white brighter, add more glue. Be careful to observe that every layer is dry, before you put on another. If you work upon wood, you must put on a dozen; but six or seven are sufficient if your paper is thick. Afterwards dip a soft brush in some water, draining it with your fingers; rub the work with it, in order to make it the smoother. When your brush is full of white, you must wash it again; and also change the water when it is too white. Or you may use a wet linen rag, instead of a brush.

Yellows. In some objects there may be seen a shining, like that of gold, through colours of red, blue, or green; such as some sorts of flies or beetles, and the cantharides. This gold or transparency may be well imitated by laying some leaf-gold on the shaded side of the drawing, giving a little to the light side. To lay on the gold-leaf, press it smooth and close with cotton, after you have washed it with strong gum-water; but care must be taken, that in laying on the gum, you do not exceed the limits through which you would have the gold appear. In this case, the gold is only to shine through the transparent colour, which is to be laid over it.

As leaf-gold will not receive water-colours regularly, it is necessary to be provided with water of ox-gall, and with this liquor to stroke over the gold-leaf; by which it will receive any colour you are desirous of laying over it, and will also retain it.

In some manuscripts there may be seen gold letters, which seem to rise above the surface of the paper. The composition which raises them, is made of vermilion and the white of an egg, beaten to the consistence of an oil, and fixed to the paper with gum-arabic; on this figurative letter, wash some strong gum-water, with a camel's-hair pencil; lay on the gold-leaf close with some cotton; and when dry, rub it again with cotton, and burnish it with a dog's tooth, and it will appear as if it was cast in gold.

There is also another way of working in gold, which is perfomed by shell-gold (but then it must be pure, and not that brought from Germany, which turns green in a few days). Cover the shady parts with vermilion, before you use this gold, and when you have rectified it with spirit of wine, lay it on; when dry, burnish it as before directed.

In laying on this gold, it is best to leave the lights without it, as it will appear to a much greater advantage than if all the objects were covered: but, provided the whole performance should chance to be covered, the best way of setting it off, is to trace over the shady parts with gall-stone, or the yellow made of French berries, (of which we shall treat hereafter), heightened with minium.

Of yellows in general. Gamboge is, beyond doubt, one of the mellowest colours nature has produced; it is of so mild a temperature, that when it is touched with any fluid, it instantly dissolves; so that, consequently, it wants neither gumming nor grinding; it is productive of a variety of the most agreeable and pleasant yellow tints, that fancy or art could ever imagine; it will generally shade itself, though sometimes it requires help.

Gall-stone is a very rich deep yellow, tending towards a brown; it is exceedingly useful in many cases, needs but little gumming or grinding, works free, but will not shade itself.

Mr. Boyle says, if you cut the roots of berberries, and put them into a strong lixivium, made of pearl-ashes and water, from them will proceed a very agreeable yellow. This experiment has often been made, and as often attended with success.

He also gives an account of another fine transparent yellow, by boiling the root of a mulberry-tree, well cleansed, in the foregoing lixivium.

Yellow ochre makes a very good pale yellow: and, being ground with gum-water, will prove extremely useful.

Another very useful yellow, is made by infusing the plant celandine in clear water, gently pressing it, adding to the liquor some alum-water, letting it boil.

The virtue of the yellow extracted from French berries is so well known, that we need only give the directions for preparing it: In a quart of the preceding lixivium, boil two ounces of French berries, till the liquor is of a fine yellow; strain it from the yellow berries, and when cold it is fit for use. To the berries put a pint of the same lixivium, and boil it till the liquor is as strong as gall-stones; with which you may shade any yellows; this you may boil till it comes to a brown, and will, with the addition of a little ox-gall, serve to shade the gold-leaf.

You may likewise make a yellow, by infusing saffron in pure water. When this is steeped in rectified spirit of wine, there is nothing higher; but it is very apt to fly, unless it is high-gummed.

A good yellow, for the illumination of prints, may be extracted from the roots of ginger; which make a good green, when mixed with transparent verdigrise.

Those yellows called English and Dutch pinks, are made with French berries, ground to a fine powder, and then boiled.

King's yellow, a fine body-colour, is much used in heightening the ochre for gold lace, &c.

Orange colour. This colour is made of a mixture of vermilion and gamboge, the latter most predominant, in which you have a serviceable colour in painting lilies, and all other orange-coloured flowers. Orpiment is likewise a pleasing colour.

Reds.

Red-lead, or minium, is a strong heavy colour. Mr. Boyle has given us the following directions for preparing it: Put four ounces in a glass, to a quart of rain-water, and when it has been thoroughly stirred, pour off the water; and by a frequent repetition of this, there will remain at the bottom of the glass a beautiful red, when dry, which is to be used with gum-water. When the colour has been thus prepared, you must not expect above twenty grains to remain out of four ounces.

Carmine affords the brightest and most perfect crimson, and is the most beautiful of all reds; for with this colour and lake you may make the shades as strong as you please. This colour should never be purchased but by day-light; for if not good, it will but spoil your work.

Lake is a fine transparent colour, not much inferior to carmine; but in painting with carmine on that part of the print on which the light is supposed to strike, lay on the first tint as light as possible, working it stronger as it grows darker, and touch it in the darker parts with lake.

Lake may be bought at most colour-shops, ready prepared for water-colours; but if you are desirous of making it yourself, it is necessary to adhere to the following directions: Having prepared a lixivium, made with the ashes of vine-twigs, to three pints of it add a pound of the best ground brazil wood; boil it till half the lixivium is evaporated; strain of off; boil it again with the addition of four ounces of fresh brazil wood, two ounces of cochineal, half an ounce of terra marita, and a pint of fair water; let it evaporate as before; add half an ounce of burnt alum (reduced to an impalpable powder), a quarter of a drachm of arsenic; dissolve them in it, by stirring it with a stick; when settled, strain it. To give this a body, reduce two cuttle-fish bones to a powder, and putting it in, let it dry leisurely. Grind it in a quantity of fair water, in which you may let it steep; strain it through a cloth, and making it into a few cakes, set it by for use, after drying it on a piece of marble.

If you would have this lake redder, add some of the juice of a lemon; and to make it deeper, add oil of tartar.

Another lake: Boil the shreds of superfine scarlet cloth in a lye made of the ashes of burnt tartar; when sufficiently boiled, add some cochineal, powdered mastich, and roche alum; boil this again; while it is quite hot, strain it through a bag several times. The first time, the bag must be strained from top to bottom, and the remaining gross matter being taken out, let the bag be well washed; after this, strain the liquor through the bag again, and you will find a paste remaining on the sides, which divide into small cakes, and set by for use.

Another lake: Steep four ounces of the best brazil wood in a pint and a half of the finest distilled vinegar, for three weeks at least, though the longer it remains the better it is; seethe the whole in balneum mariæ, till it boils up three or four times; let it settle for a day or two; put it to an ounce of powdered alum, and into a clean pan with the liquor; let it remain for twenty-four hours; heat the composition, and stir it till it is cold; when it has stood about twelve hours, strain it, and add two cuttle-fish bones, prepared as before.

A liquid colour of a very good crimson, is made as follows: In twelve ounces of pale stale beer, boil one ounce of ground brazil wood, till the colour is as strong as you desire; strain it through a linen cloth, and bottle it up for use. If you want to bring this colour to a body, take some dried ox-blood, reduced to a powder, and mix it with the colour.

We have the following directions from Mr. Boyle, for extracting a fine crimson from the berry-bearing spinach, which, being pressed, affords a very agreeable juice; to which add a fourth part of alum; boil it, and when cold it is fit for use.

Or you may extract a very beautiful red from the red beet-root, baked with a little strong vinegar and alum: when cold it is fit for use.

Another way to make a crimson: Put twenty or more grains of bruised cochineal into a gallipot, with as many drops of the lye of tartar as will make it give forth its colour; add to this mixture about half a spoonful of water, or more, and you will have a very agreeable purple; reducing some alum to a very fine powder, put it to the purple liquor, and you will have a beautiful crimson; strain it through a fine cloth; use it as soon as possible: for though this is a colour which, if soon used, looks extremely well, yet by long standing it is subject to decay.

Indian lake is far superior to any other of the kind, for the deep shade of reds of all kinds, and works as free as gamboge. The best is brought from China, in pots, and has the appearance of raspberry-jam, but very bitter to the taste: it requires no gum.

Purples. Take eight ounces of logwood, a pint of rain water, and an ounce of alum; infuse it well over a slow fire, in a well glazed pan or pipkin, for about twenty-four hours; add a quarter of an ounce of gum-arabic, let it stand for a week: strain it through a piece of fine cloth. Keep it close, or it will mould.

Or you may make a redder purple, by adding to one ounce of the above, four ounces of brazil wood, and a pint of stale beer, boiling it till the liquor is as strong as you desire. It may be made darker, by adding more logwood.

The richest purple is made by blending carmine and Prussian blue, or indigo, to what shade you please.

Blues. Ultramarine is the best and brightest blue. Prepare it by heating six ounces of the lapis lazuli till it is red; cool it in strong vinegar; grind it with a stone and muller to an impalpable powder; then make a composition of bees'-wax, resin, linseed-oil, and turpentine, of each three ounces; incorporate the whole together over a slow fire, till it is near boiling; pour them into a pan well glazed. This is called the paste of ultramarine. The lapis lazuli being prepared, add to it an equal quantity of the pastil, or paste; mix them together thoroughly, and let them remain twelve hours. To extract the ultramarine from the paste, pours clear water upon it; on pressing the paste with your hands, the ultramarine will come out for its reception, place a glass tumbler under your hand; let it settle in this water till the ultramarine sinks to the bottom.

If the colour seems foul, cleanse it thus: Dissolve some tartar in water; add as much of it to the ultramarine as will cover it; let it stand twelve hours; wash it in warm water, and you will have your colour well clarified and perfectly clean. Let your ultramarine be of a high colour, and well ground.

Next to ultramarine in beauty, is Prussian blue; but it does not grind kindly with water, on account of its oily substance.

Blue bice is a colour of a very good body, and flows very agreeably in the pencil; wash it according to the rules laid down for ultramarine.

Blue verditer is a very bright pleasant blue, of a good body, and works well when ground with gum-water. It is a little inclinable to, and makes a very good green, when ground with gamboge, or French berries. This blue is mostly used for a sky, or a garment.

Sanders blue is extremely serviceable in the shading of ultramarine, where no very dark shades appear; when they do, you may add a little indigo to it.

Litmus is a very agreeable blue. To prepare it, take a quart of small-beer wort, in which boil two ounces of litmus, till the colour is as strong as you require; pour the liquor into a glazed pipkin, and it will soon congeal. See Archil.

Indigo is the darkest blue, is a soft free colour, and runs very warm in the pencil; it requires to be well washed and ground; and may be made darker or lighter, by the addition of more or less gum-water. Care is required in using this colour; for, as we before hinted, its running so free may be a means of deceiving the student, and prove too dark for his purpose.

Mr. Boyle has given us the following directions for making a very fine colour of the blue leaves of rue: by pressing, bruising, and infusing both leaves and juice in pure water, for a fortnight, washing them every day, incorporating them and the water till they become a pulp, letting them dry gradually. These will produce an excellent blue for shading, which runs free in the pencil; put it into the powder of gum-arabic, which will be a means of making it keep; add of the gum as you would have it more or less stiff in working.

A fine transparent blue (from the preceding author), equal to a tint of ultramarine: The flower from which this blue is extracted, is the centauria cyanus, or blue cornbottle, possessed of two blues, the outer leaves being light, and the inner dark; the latter is held in preference; pick both from the buttons and cases in which they grow, the same day they were gathered. Having prepared a quantity of the middle leaves, press out as much juice as possible; with the addition of a little alum, you will be possessed of a fine, durable, transparent blue, little inferior to ultramarine. The procuring of the flowers, and the pressure of the juice, should be done with all possible expedition, lest the flowers should lose their perfection. It has been thought by some, if the leaves of these flowers were cured as those of saffron, there would proceed from them a much greater quantity of colour, from which might be pressed more tincture than when fresh from the field. In curing of each it would appear, that each time the cake was turned, the flowers would be darker, till they become a dark blue. Great care is required in this operation, that the fire is kept very constant and gentle, that the flowers may not be scorched, which will be an incontestable way of bringing the flowers to perfection. Therefore, to put this operation in execution, a kiln must be procured, as for curing saffron, the top of which is to be covered with hair-cloth; upon this lay several sheets of paper; afterwards a parcel of the inner leaves of the flowers, two or three inches thick, pressing them close, and sprinkling them with gum-water; after which, a small charcoal fire must be made in the kiln, o as to communicate the heat to the top. over the cake with a few sheets of paper, nd a board, with a small weight upon it; fter a few minutes, the cake is to be turned; hen it is placed, take off the upper paper, prinkle the cake again with gum-water, lay n the board a weight as before for a few mi- utes; and so repeat the turning and sprin- ling several times, till the cake is united, and f the thickness of a cake of saffron.

Blacks. The proper blacks for water-co- ours are as follow:

Ivory-black, which is prepared in the fol- owing manner: Let the ivory-black be tho- oughly ground, and there will naturally pro- eed from it a liquor of an oily substance; ix as much of it as will make it work freely the pencil. It has a fine gloss, and is ex- emely serviceable in painting of shining bjects.

There is another very agreeable and useful ack, called Keating's black, which may be ad at most colour-shops ready-prepared.

Indian ink is a very good black, and of eat service, as it may be laid on to any hade, and will always shade itself; on which count it is often used for drawings.

Greens. Sap-green is a colour extremely rviceable, and the best green for water-co- urs our age affords, being of a gummy sub- ance, and diluting easily in water. It pro- uces an endless variety of tints, and has the lvantage of shading itself. In purchasing is colour, remember to observe that it oks very black and bright.

A sea or artificial green, is made by mix- g indigo and sap-green, which may be made rker or lighter by adding more or less digo; it is a very serviceable colour, easily orked, and productive of many tints. This olour, as well as sap-green, shades itself. he indigo must be well ground before you ix it.

Another is made with indigo and gamboge, ell ground together, extremely useful in inting of trees, grass, vegetables, &c. With e addition of sap-green, it is very service- le in flowers, and shading in of garments.

A transparent green is made by mixing rdigrise and yellow to various tints, by aving either predominant.

Browns. Burnt and unburnt terra de Si- na, are the warmest brown for front grounds, ad leaves, &c. work very free, and are of neral use.

Bistre is a good and serviceable colour. e best sort is very bright and close; as it a colour difficult to work of itself, mix a tle Spanish liquorice with it, that will mel- w and take off its harshness. It must be ll ground; and the higher it is gummed, e better for use.

Spanish liquorice is allowed, by the best asters, to be productive of a great variety of own tints, of a very agreeable colour; it ll not shade itself, but works as free as any m-colours by diluting it in fair water.

A brown mixture is made by incorporating -green and carmine, which is of an extra- dinary soft nature; it is a colour extremely viceable in painting flowers in water-co- rs.

Another, by blending vermilion and bistre oroughly; the bistre must be extremely ll ground before you incorporate it with vermilion, and it will produce a very good own.

Directions for preparing the following mixed colours.

Ash colour. Ceruse, Keating's black, and white, shaded with cherry-stone black.

Bay. Lake and flake white, shaded with carmine; bistre and vermilion, shaded with black.

Changeable silk. Red lead and masticot-water, shaded with sap-green and verdigrise.

Another. Lake and yellow, shaded with lake and Prussian blue.

Cloud colour. Light masticot, or lake and white, shaded with blue verditer.

Another. Constant white and Indian ink, a little vermilion.

Another. White, with a little lake and blue verditer, makes a very agreeable cloud-colour, for that part next the horizon.

Crimson. Lake and white, with a little vermilion, shaded with lake and carmine.

Flame colour. Vermilion and orpiment, heightened with white.

Another. Gamboge, shaded with minium and red-lead.

Flesh colour. Ceruse, red lead, and lake, for a swarthy complexion, and yellow-ochre.

Another. Constant white and a little carmine, shaded with Spanish liquorice, washed with carmine.

French green. Light pink and Dutch bice, shaded with green pink.

Glass grey. Ceruse, with a little blue of any kind.

Hair colour. Masticot, ochre, umber, ceruse, and cherry-stone black.

Lead colour. Indigo and white.

Light blue. Blue bice, heightened with flake white.

Another. Blue verditer, and white of any sort, well ground.

Light green Pink, smalt, and white.

Another. Blue verditer and gamboge.

Another. Gamboge and verdigrise. The chief use of this green is to lay the ground-colours for trees, fields, &c.

Lion tawny. Red lead, and masticot, shaded with umber.

Murrey. Lake and white lead.

Orange. Red lead and a little masticot, shaded with gall-stone and lake.

Orange tawny. Lake, light pink, a little masticot, shaded with gall-stone and lake.

Pearl colour. Carmine, a little white, shaded with lake.

Popinjay green. Green and masticot; or pink and a little indigo, shaded with indigo.

Purple. Indigo, Spanish brown, and white; or blue bice, red and white lead; or blue bice and lake.

Russet. Cherry-stone black and white.

Scarlet. Red lead and lake, with or without vermilion.

Sea green. Bice, pink, and white, shaded with pink.

Sky colour. Light masticot and white, for the lowest and lightest parts; second, red ink and white; third, blue bice and white; fourth, blue bice alone. These are all to be softened into one another at the edges, so as not to appear harsh.

Sky colour for drapery. Blue bice and ceruse, or ultramarine and white, shaded with indigo.

Straw colour. Masticot and a very little lake, shaded with Dutch pink.

Violet colour. Indigo, white, and lake; or fine Dutch bice and lake, shaded with indigo; or litmus, smalt, and bice, the latter most predominant.

Water. Blue and white, shaded with blue, and heightened with white.

Another. Blue verdigrise, shaded with indigo, and heightened with white.

Directions for using the colours.

Your pencils must be fast in the quills, and sharp-pointed (after you have drawn them through your mouth), not apt to part in the middle.

Before you begin, have all your colours ready, and a pallette for the conveniency of mixing them; a paper to lay under your hand, as well as to try your colours upon; also a large brush, called a fitch, to wipe off the dust from them.

Being prepared according to the foregoing method, proceed in your painting; which if a landscape, lay on first dead colours freely all over your piece, leaving no part uncovered.

Having laid your dead colours, begin next with the lighter parts, as the sky, sun-beams, &c.; then the yellowish beams, with masticot and white; next the blueness of the sky, with blue verditer alone; for purple clouds, mix only lake and white, making your colours deeper as they go upwards from the horizon, except in tempestuous skys. The tops of distant mountains must be worked so faint, that they may seem to lose themselves in the air.

Bring your colours forward as your distance decreases: painting your first ground next the horizon, downwards, of a bluish sea-green; and as you advance forward, of a darker green, till you come to the fore-ground itself; which, as it is the darkest part of all, with dark green, worked in such a manner as to give the appearance of shrubbery, &c.

In painting trees, having first laid a verdigrise green for a dead colour, proceed with working it so as to give a leafy appearance. Bring some of your leaves forward with masticot and white; for the trunk, work the brown with sap-green; if you should introduce oak-trees, lay on some touches to express leaves of ivy twined about it.

All distinct objects are to be made imperfect, as they appear to the eye.

In painting flesh, the following are the best directions for preparing your work so as afterwards more readily to produce the effects of colours seen in nature:

Take flake-white and a little lake, blend them together, and with that lay the ground-colour; then shade with red-ochre, cherry-stone black, and a little lake, mixed together, touching the lips, cheeks, &c. with a tint of carmine, and heighten the flesh with white and a little carmine. Remember that you are never to heighten it with pure white, which will always give it a cold appearance.

The peculiar management of tints in the representation of other various kinds of objects, such as animals, flowers, fruits, &c. will require some attention from the student, but is unnecessary to be given here in detail, as practice will soon instruct him in all that is requisite on this head.

It may be recommended to the student in general, whatever is the subject of his drawing, not to finish any one part first, but to work up every part gradually alike, until he finds nothing wanting to complete the whole.

Wherever he lays on strong touches, he must be careful in those places to bring up his work to an equal roundness and strength, tempering and sweetening the colours with a sharper pencil than the first, that no lumps or harsh edges may be left, but that the shadows may all lie dispersed, soft and smooth, and gliding gently into one another.

The occasional roughness of your work need not discourage you: for it is easily softened by degrees, with other tints and shadows; observing only to sweeten, mellow, and heighten them, according as the light happens to fall.

A method has been lately discovered of combining the effects of water-colours with those of crayon-painting, by means of wax crayons. It is an ingenious and pleasing mode of practice. See Wax Crayons.

Various receipts for the use of those who paint in water-colours.

Boil two ounces of the best and clearest glue, with one pint of clear water, and half an ounce of the finest roche-alum, till dissolved. This is a very serviceable liquor, with which you may temper those colours intended for sky, as it will prevent them from cracking.

To make a solution of gum. Dissolve an ounce of the best white gum-arabic, and half an ounce of double refined sugar, in a quart of spring water; strain it through a piece of muslin, then bottle it off for use, keeping it free from dust.

Another method. Take the whitest sort of gum-arabic, bruise and tie it in a piece of woollen cloth, steep it in spring water till dissolved. If too stiff, which is known by the shining of the colours, add more water; if too weak, more gum. With this water you may temper most of your colours, using such a quantity of it, that the colours, when dry, being touched, will come off.

To keep the flies from your work. Having prepared your gum-water according to either of the preceding directions, add a little coloquintida, which, if your performance should be exposed, will keep it from being damaged by the flies.

To prepare alum-water. Take four ounces of roche-alum, and a pint of pure spring water; boil it till the alum is thoroughly dissolved; filtre it through blotting-paper, and it is fit for use.

Before you lay on the colours, take some of this water hot, and with a sponge wet the back of the paper, which, if not good, must be wetted three or four times. This will not only prevent the sinking of the colours, but will also keep them from fading, and give an additional beauty and lustre. Remember that the paper must be dried each time before you wet it again.

To make lime-water. Put some unslacked lime in a well-glazed pan; cover it with pure water one inch above the lime; let it remain so for one day, then strain off the water, and keep it for use. By the means of this water, you may change sap-green into blue.

To make a lixivium of pearl-ashes. Steep half an ounce of pearl-ashes in clear water for one day; strain off the water as clean as possible; this infusion will prove extremely serviceable in many colours, particularly brazil wood, to which it will give an additional beauty and lustre.

To recover decayed colours. Take double-distilled rosemary-water, or pure essence of rosemary, and with a few drops temper your colours, which, however dead or faded, will recover their primitive brilliancy. This essence will prevent the bubbles which are troublesome in grinding white and umber.

To prepare a liquid gold for vellum-painting, fans, &c. Having procured some of the finest leaf gold, grind it with strong gum-water, adding more gum-water as you see requisite; when thoroughly ground, temper it with a small quantity of mercury sublimate, binding it in the shell with a little dissolved gum; spread it equally over the shell, and use it with fair water only.

A liquid silver, for the same use. The manner of making this is the same as that of liquid gold, only remembering to temper it with glaire of eggs, and not water.

To make the glaire of eggs. Beat the whites with a spoon till they rise in a foam; let them stand 12 hours, and they will be clarified into good glaire.

To recover liquid silver that has contracted rust. If your silver becomes rusty, cover that part of the performance with the juice of garlic, which will recover it effectually.

To make a single ground to lay silver or gold upon. Take the new shreds of parchment (they being preferable to glove-leather), boil them in a quart of spring-water till consumed to a pint; strain the size from the shreds, and put it into a well-glazed pan; use it before it is cold. Be careful, when you lay on your silver or gold, that your size is not too moist, nor too dry, for in either case you will be in danger of impairing your performance.

The method of making size for candle-light pieces, has already been described.

WATER COURSE. A water course does not begin by prescription, nor assent, but begins ex jure naturæ, having this course naturally; and cannot be diverted. 3 Bulst. 340.

WATERMEN. In London the lord mayor and court of aldermen have much power in governing the company of watermen, and appointing the fares for plying on the river Thames; and justices for Middlesex, and other adjoining counties, have also power to hear and determine offences, &c. See 10 G. II. c. 31.

WATER-SPOUT, an extraordinary aqueous meteor, most frequently observed at sea. It is a truly formidable phenomenon, and is indeed capable of causing great ravages. It commonly begins by a cloud, which appears very small, and which mariners call the squall; which augments in a little time into an enormous cloud of a cylindrical form, or that of a reversed cone, and produces a noise like an agitated sea, sometimes emitting thunder and lightning, and also large quantities of rain or hail, sufficient to inundate large vessels, overset trees and houses, and every thing which opposes its violent impetuosity.

These water-spouts are more frequent at sea than by land; and sailors are so convinced of their dangerous consequences, that when they perceive their approach, they frequently endeavour to break them by firing a cannon before they approach too near the ship. They have also been known to commit great devastations by land: though, where there is no water near, they generally assume the harmless form of a whirlwind. To enable the reader to understand their nature, we shall preface the different theories by a short description of one of these wonderful appearances, as given by the celebrated M. Tournefort in his Voyage to the Levant:

"The first of these," says this traveller, "that we saw, was about a musket-shot from our ship. There we perceived the water began to boil, and to rise about a foot above its level. The water was agitated and whitish; and above its surface there seemed to stand a smoke, such as might be imagined to come from wet straw before it begins to blaze. It made a sort of a murmuring sound, like that of a torrent heard at a distance, mixed, at the same time, with a hissing noise, like that of a serpent: shortly after we perceived a column of this smoke rise up to the clouds, at the same time whirling about with great rapidity. It appeared to be as thick as one's finger; and the former sound still continued. When this disappeared, after lasting for about eight minutes, upon turning to the opposite quarter of the sky, we perceived another, which began in the manner of the former; presently after a third appeared in the west; and instantly beside it still another arose. The most distant of these three could not be above a musket-shot from the ship. They all continued like so many heaps of wet straw set on fire, that continued to smoke and to make the same noise as before. We soon after perceived each, with its respective canal, mounting up in the clouds; and spreading, where it touched the cloud, like the mouth of a trumpet; making a figure, to express it intelligibly, as if the tail of an animal was pulled at one end by a weight. These canals were of a whitish colour, and so tinged, as I suppose, by the water which was contained in them; for, previous to this, they were apparently empty, and of the colour of transparent glass. These canals were not straight, but bent in some parts, and far from being perpendicular, but rising in their clouds with a very inclined ascent. But what is very particular, the cloud to which one of them was pointed happening to be driven by the wind, the spout still continued to follow its motion without being broken; and passing behind one of the others, the spouts crossed each other, in the form of a St. Andrew's cross. In the beginning they were all about as thick as one's finger, except at the top, where they were broader, and two of them disappeared; but shortly after the last of the three increased considerably, and its canal, which was at first so small, soon became as thick as a man's arm, then as his leg, and at last thicker than his whole body. We saw distinctly, through this transparent body, the water, which rose up with a kind of spiral motion; and it sometimes diminished a little of its thickness, and again resumed the same; sometimes widening at top, and sometimes at bottom; exactly resembling a gut filled with water, pressed with the fingers, to make the fluid rise or fall; and I am well convinced that this alteration in the spout was caused by the wind, which pressed the cloud, and compelled it to give up its contents. After some time its bulk was so diminished as to be no thicker than a man's arm again, and thus swelling and diminishing, it at last became very small. In the end, I observed the sea which was raised bout it to resume its level by degrees, and ie end of the canal that touched it to become s small as if it had been tied round with a ord; and this continued till the light, striking through the cloud, took away the view. still, however, continued to look, expecting that its parts would join again, as I had efore seen in one of the others, in which the pout was more than once broken, and yet gain came together; but I was disappointed, or the spout appeared no more."

Whirlwinds and water-spouts are by the majority of philosophers referred to the same rigin, and some have endeavoured to account for them on electrical principles. They bserve that the effluent matter proceeds rom a body actually electrified towards one which is not so; and the affluent matter proceeds from a body not electrified towards one which is actually so. These two currents occasion two motions analogous to the electrical attraction and repulsion. If the current of the effluent matter is more powerful than the affluent matter, which in this case is composed of particles exhaled from the earth, the particles of vapours which compose the cloud are attracted by this effluent matter, and form the cylindrical column, called the descending water-spout; if, on the contrary, the affluent matter is the strongest, it attracts a sufficient quantity of aqueous particles to form gradually into a cloud, and this is commonly termed the ascending water-spout. It is farther observed of water-spouts, that the convergence of winds, and their consequent whirling motion, was a principal cause in producing that effect; but there are appearances which can hardly be solved by supposing that to be the only cause. They often vanish, and presently appear again in the same place: whitish or yellowish flames have sometimes been seen moving with prodigious swiftness about them, and whirlwinds are observed to electrify the apparatus very strongly. The time of their appearance is generally those months which are peculiarly subject to thunder-storms; and they are commonly preceded, accompanied, or followed, by lightning, the previous state of the air being alike in both cases. And the long-established custom which the sailors have of presenting sharp swords to disperse them, is no inconsiderable circumstance in favour of the supposition of their being electrical phenomena. Perhaps the ascending motion of the air, by which the whirling is produced, may be the current known to issue from electrified points, as the form of the protuberance in the sea is somewhat pointed, and the electrified drop of water may afford considerable light in explaining this appearance.

A different theory is, however, adopted by other respectable philosophers; and it is possible after all, that there may really be two kinds of water-spouts, the one the effect of the electrical attraction, as digested above, and the other caused by a vacuum, or extreme and sudden rarefaction of the air.

It is well known that even a common fire produces a kind of circulation of the air in a room, but in a different form. It is therefore not difficult to conceive, that when any part of the column of air upon the surface of the earth or water is suddenly rarefied, either by electricity or any other cause, a vacuum, at least comparatively to the rest of the air, will immediately take place, and the circumambient air rushing in at once from every quarter to fill the void, a conflict of winds ensues, and consequently a circular motion, by which light bodies will be taken up and turned round with considerable velocity; this violent rushing of the air on all sides into the vacuum then forms what is commonly called at land a whirlwind.

When this vacuum takes place at sea, from the nature of fluids, the water will rise to a certain height by the pressure of the atmosphere, as in a common pump; but as the vacuum is not quite perfect, the water will be divided into drops; and as these vacuums are generally caused by heat, it will be rarefied when it reaches the upper regions of the atmosphere, and assume the appearance of a cloud.

Mr. Oliver, whose theory we have adopted with little variation, illustrates the phenomenon by a very easy experiment. In a stiff paper card he made a hole just large enough to insert a goose quill; after cutting the quill off square at both ends, he laid the card upon the mouth of a wine glass, filled with water to within a fifth or sixth part of an inch from the lower orifice of the quill; then applying his mouth to the upper part, he drew the air out of the quill, and in one draught of his breath drew in about a spoonful of water; and this he was able to repeat, the quill remaining as before. The water, he adds, did not ascend to his mouth in a stream, as it would have done had the quill reached the water, but broken, and confusedly mixed with the air which ascended with it. The usual phenomena of water-spouts are exactly agreeable to this theory. They appear at a distance like an inverted cone, or the point of a sword, which is owing to the water rising in large drops at the first, and being expanded as it ascends; and a cloud is generally suspended over the body of the phenomenon. The water which is taken up is undoubtedly salt at the first, but by the rarefaction in the superior regions, it undergoes a kind of natural distillation, and loses all the heavy saline particles with which it was charged. Water-spouts have been observed at land, of which two very remarkable instances are recorded in the Philosophical Transactions. Other phenomena have been remarked, which can be explained upon these principles only. Accounts have been given of red and yellow rain, of frogs and tadpoles, and even of small fishes; having been rained upon the tops of houses. The red and yellow rain was probably composed of the blossoms of vegetables, or of insects, taken up by one of these aerial tubes; and the frogs and fishes were probably part of the contents of some pond, in which the water-spout originated, or over which it might have passed in its perambulation.

The point or cone of the water-spout is generally oblique, depending on the force and direction of the wind which drives it along.

Dr. Perkins, of Boston, is disposed to adopt a different theory of water-spouts. Capt. Melling informed him, that in a voyage from the West Indian islands to Boston, a water-spout came across the stern of the vessel where he then was, a flood of water fell upon him with such violence as almost to beat him down, and the spout immediately passed off with a roaring noise into the sea. The water from the spout was perfectly fresh. Mariners in general affirm that water descends from the clouds through the water-spout into the sea, and hence it is inferred that a whirlwind cannot be the cause of a water-spout, nor can both of these phenomena proceed from the same cause.

Water-works, in general, denote all manner of machines moved by, or employed in raising or sustaining water; in which sense water-mills of all kinds, sluices, aqueducts, &c. may be called water-works. See Mill, &c.

WATSONIA, a genus of the class and order triandria monogynia. The calyx is six-parted; stigmas three, bifid; capsules triangular. There are six species, bulbs of the Cape.

WAVED. See Wavey.

WAX. The upper surface of the leaves of many trees is covered with a varnish, which may be separated and obtained in a state of purity, and is found to possess all the properties of bees'-wax: hence it is justly inferred that wax is a vegetable product, and that the bees extract it unaltered from the leaves of trees and other vegetable substances that contain it. Several plants contain wax in such abundance as to make it worth while to extract it from them. We shall now consider the properties of bees'-wax.

Wax, when pure, is of a whitish colour: it is destitute of taste, and has scarcely any smell. Bees'-wax indeed has a pretty strong aromatic smell; but this seems chiefly owing to some substance with which it is mixed; for it disappears almost completely by exposing the wax, drawn out into thin ribands, for some time to the atmosphere. By this process, which is called bleaching, the yellow colour of the wax disappears, and it becomes very white. Bleached wax is not affected by the air. Its specific gravity is 0.9600.

Wax is insoluble in water; nor are its properties altered though kept under that liquid.

When heat is applied to wax it becomes soft; and at the temperature of 142°, if unbleached, or of 1550° if bleached, it melts into a colourless transparent fluid, which concretes again, and resumes its former appearance as the temperature diminishes. If the heat is still farther increased, the wax boils and evaporates: and if a red heat is applied to the vapour, it takes fire and burns with a bright flame. It is this property which renders wax so useful for making candles.

Wax is scarcely acted on by alcohol when cold, but boiling alcohol dissolves a portion of it. This was first observed by Dr. Pearson, and has been since verified by Dr. Bostock. Rather more than 20 parts of alcohol are necessary to dissolve one part of wax; and as the solution cools the greater part of the wax precipitates, and the remainder is thrown down by water.

Ether has but little action on wax while cold; but when assisted by heat, it takes up about $\frac{1}{20}$ of its weight of it, and lets the greatest part precipitate on cooling.

Wax combines readily with fixed oils when assisted by heat, and forms with them a substance of greater or less consistency according to the quantity of oil. This composition, which is known by the name of cerate, is much employed by surgeons.

The volatile oils also dissolve it when heated. This is well known, at least, to be the case with oil of turpentine. A part of the wax precipitates usually as the solution cools, but of a much softer consistence than usual, and therefore containing oil.

The fixed alkalies combine with it, and form a compound which possesses all the properties of common soap. When boiled with a solution of fixed alkalies in water, the liquid becomes turbid, and after some time the soap separates and swims on the surface. It is precipitated from the alkali by acids in the state of flakes, which are the wax very little altered in its properties. Punic wax, which the antients employed in painting in encaustic, is a soap composed of 20 parts of wax and one of soda. Its composition was ascertained by Mr. Lorgna.

When boiled with liquid ammonia, it forms a kind of soapy emulsion. As the mixture cools, the greatest part of the compound rises to the surface in the state of white flakes. This soap is scarcely soluble in water.

The acids have but little action on wax; even oxymuriatic acid, which acts so violently on most bodies, produces no other change on it than that of rendering it white. This property which wax possesses, of resisting the action of acids, renders it very useful as a lute, to confine acids properly in vessels, or to prevent them from injuring a common cork.

Mr. Lavoisier, by means of the apparatus which he employed in the analysis of alcohol and oils, contrived to burn wax in oxygen gas. The quantity of wax consumed was 21.9 grains. The oxygen gas employed in consuming that quantity amounted to 66.55 grains. Consequently the substances consumed amounted to 88.45 grains. After the combustion, there were found in the glass vessel 62.58 grains of carbonic acid, and a quantity of water which was supposed to amount to 25.87 grains. These were the only products.

Now 62.58 grains of carbonic acid gas contain

44.56 of oxygen, and	18.02	of carbon; and 25.87 grains of water contain
21.99 of oxygen, and	3.88	of hydrogen
66.55	21.90	

Consequently 21.9 parts of wax are composed of 18.02 of carbon and 3.88 of hydrogen. And 100 parts of wax are composed of

82.28	carbon
17.72	hydrogen
100.00	

But this analysis can only be considered as an approximation to the truth; the quantity of water being only estimated, and that of the gas being liable to uncertainty. There can be no doubt, from the litttle action of acids on wax, that it contains oxygen as an ingredient. We must therefore consider it as a triple compound of carbon, hydrogen, and oxygen; but the proportions are unknown.

If wax is distilled with a heat greater than 212°, there comes over a little water, some acid, a little very fluid and odorous oil: the oil, as the distillation advances, becomes thicker and thicker, till at last it is of the consistency of butter, and for this reason has been called butter of wax. There remains in the retort a small quantity of coal, which is not easily reduced to ashes. When the butter of wax is repeatedly distilled, it becomes very fluid, and assumes the properties of volatile oil.

Wax possesses all the essential properties of fixed oil. We must therefore consider it as a fixed oil rendered concrete. Now that species of fixed oils, distinguished by the epithet fat, have the property of becoming concrete, and assuming the appearance of wax when exposed long to the air; in consequence, it is supposed, of the absorption of oxygen. Hence probably the difference between wax and fixed oils consists in the oxygen which it contains as a component part. The wax at its first formation was in all probability in the state of a fixed oil; but by the absorption of oxygen it gradually concreted into wax. Wax, then, may be considered as a fixed oil saturated with oxygen.

It is natural to suppose, if this theory is just, that fixed oil will occur in plants in various states of hardness: and this accordingly is the case. Sometimes it is of the consistency of butter, and this is denominated a butter; thus we have the butter of cacao, the butter of coco, the butter of galam. Sometimes it is of a greater consistency, and then is denominated tallow; thus we have the tallow of the croton, extracted by boiling water from the fruit of the croton sebifera. When its consistency is as great as possible, it then takes the appellation of wax. Thus we have the myrtle wax of America extracted from the berries of the myrica cerifera, and the pela of the Chinese. The species of wax, then, which exist in the vegetable kingdom, may possibly be as numerous as the fixed oils. Let us take a view of some of the most remarkable.

Bees'-wax is the species whose properties have been described in the former part of this article. It is supposed that the bees collect it from plants; but it has been very well ascertained, that in many cases at least they manufacture it from honey, and even from sugar: for bees confined and fed solely upon these substances produce wax. Its consistency is said to be less when the bees are confined to sugar than when they are allowed honey.

The myrtle wax of North America is obtained from the myrica cerifera. We are indebted to Dr. Bostock and Mr. Cadet for a very exact account of its properties and extraction. The myrica cerifera is a shrub which grows abundantly in Louisiana and other parts of North America. It produces a berry about the size of a pepper-corn. A very fertile shrub yields nearly seven pounds. The berries are picked off, thrown into a kettle, and covered with water to the depth of about half a foot. The kettle is then boiled, and the berries stirred and squeezed against the sides of the vessel. The wax which they contain is melted out and swims on the surface. It is skimmed off, passed through a cloth, dried, melted again, and cast into cakes. From the observations of Cadet we learn that the wax forms the outer covering of the berries. The wax thus obtained is of a pale green colour. Its specific gravity is 1.0150. It melts at the temperature of 109°; when strongly heated it burns with a white flame, produces little smoke, and during the combustion emits an agreeable aromatic odour. Water does not act upon it. Alcohol, when hot, dissolves $\frac{1}{20}$th of its weight but lets most of it fall again on cooling.

Wax Crayons. The art of painting in wax crayons is a late discovery, and when skilfully practised, is capable of producing the most pleasing effect. It is, however, rather to be considered as an adjunct to the art of water-colours, than as a distinct branch of the art of design or painting, as will appear from the nature of the materials employed in it. Instead of the substances used in conjunction with the respective colours, to form the body of common crayons, such as plaister of Paris, pipe-clay, calcined alabaster, &c. all the colours used on this new mode of painting are to be incorporated with wax. This mixture gives them the superior advantage of being particularly calculated for the execution of minute works in crayons, as they are not liable to moulder away, or to be rubbed off from the paper; but works thus executed require the assistance of various washes in water-colours to improve and perfect their effect, as, from the nature of wax, the frequent workings over of these crayons would produce an excessive smoothness, or glassiness, which would prevent the colours from attaching or taking proper hold of the surface of the work in the heightenings and last finishings, and would disappoint the artist in his endeavours to produce the greatest requisite strength of effect.

It is to be observed, therefore, that water-colours are to be used in beginning your picture, and in finishing it. When the crayons are judiciously worked over the water-colours, they will produce the appearance of an elegantly finished stippled engraving, coloured in the plate; the grain of the paper catching the crayons in dots, (when gradually laid on with a light hand) in a wonderfully pleasing manner.

We shall comprize the instructions requisite for the student's practice under the following heads, namely:

1. The kind of wax to be used in making the crayons;
2. The colours fit to be incorporated with it;
3. The choice of proper paper;
4. The method of using the crayons.

Wax. The wax proper to be used in making crayons, must be bleached bees'-wax, entirely free from adulteration. It must likewise be of the hardest kind, of which the Russian wax is the best, although in colour not quite so fine as either the American or English wax; but its hardness gives a firmness to the crayons, and prevents a greasiness which softer wax would create.

Colours. The colours proper for mixing into crayons, are the following, viz. for yellows, king's yellow or yellow oker; for blues, Antwerp or Prussian; for reds, carmine, lake, and Chinese vermilion; for browns, umber burnt and unburnt; for blacks, lamp-black only. As to compound tints, they are to be produced by a judicious management of the water-colours over the crayons; and this rule with respect to the colours proper to be used for crayons, is to be particularly observed: that none are fit for the purpose, but such as, in their dry unmixed state, will mark on paper pretty freely: for the reader may easily judge, that the tenacity of the wax would completely prevent any hard colour from working that was incorporated with it.

Having procured the kind of wax already mentioned, you are to have a nice glazed white pipkin, perfectly clean and free from any greasy particles; and having previously ground your colours on a flag with your muller, perfectly fine, in fair water, and dried, put a small quantity of wax into the pipkin, which you are to place over a very slow fire; when the wax is entirely dissolved by the gentle heat (for if it bubbles it is spoiled), gradually sprinkle in your colour, stirring it with an ivory pencil-handle, until you find it perfectly mixed; at the same time observing that you do not overload the wax with colour, as it will make the crayons too brittle; nor are you to put in too little colour, as it makes them faint and work greasy; so a medium is to be observed, to ascertain which practice only will conduce. There are some colours, such as vermilion, which, if they receive too great a heat, turn black; and that must be very cautiously observed, as vermilion, in this kind of painting, is a highly useful colour: as is also lamp-black, a harder kind of crayon from which is to be made by mixing some of it, in its raw state, with strong glue, letting it harden, and then burning it in a crucible (as directed in calcining colours for miniature painting); then pulverizing it on your flag, and mixing it with your wax, as before mentioned. This kind of black crayon is most excellent for giving sharp touches in dark parts, as it is also for making sketches to refresh the memory: is much superior to Italian chalk, as nothing will cause it to rub or spoil, it remaining as immoveable as writing-ink, and working extremely pleasant.

Paper. The paper fit to be used in wax-crayon painting, must be of the wove or vellum kind; but as of this there are several sorts, it is necessary to mention, that it must be of a middling fineness, for if too coarse, the grain will catch the crayons in dots so remote from each other, as to make your work look unpleasant; and if the paper is too fine it will not catch the crayons as it ought, but clog your painting without producing any effect. The only rule therefore for choosing your paper is to go to the stationer's, and taking a small bit of soft black crayon, by gently rubbing the crayon on a few sheets of different kinds of wove paper, you will become a judge of what is the best for your purpose, at a trifling expence. Having procured this necessary article to your satisfaction, you then proceed to work.

Method. The desk you are to work on must be much larger than the one mentioned for miniature painting, (see Miniature,) this kind of work being often used for larger sizes than that style of painting is.

Having your sitter placed in the same manner as pointed out in the article on Miniature Painting, with a soft piece of charcoal sketch faintly the distances and forms of the features: then touch them in more strongly with your crimson or black crayon, still altering until you are perfectly certain you have a correct outline, which in this kind of painting is absolutely necessary; for if in your fair drawing you commit an error in your outline, you never can alter it, the crayons being in their nature so adhesive, that nothing will remove them. Having, on your first sheet, made your outline correct, rub the back of the face part with crimson crayon, the hair part with a suitable-coloured one, and the drapery, if white, with black; then laying the paper on a fair sheet go over the lines of your sketch with a tracer, when you will transfer, in a very neat manner, your outline ready to colour in. You are then to mark in the features of your sitter more strongly with crayon or water-colour, and a fine pencil; ever observing, when you use it, to work over with a suitable-coloured crayon, as it is that which will give it the beautiful dotted appearance so much to be admired.

Having marked in the features sufficiently strong to put the likeness out of danger of being spoiled, make a wash of yellow oker entirely over the fleshy parts, deepening its tint according to your subject: wash-in the colour of the eyes, lips, hair, &c. all which being dry, work with your different-coloured crayons on the parts, until you produce the effects required; filling up any interstices of the crayons with dots of water-colours and a fine pencil. As to the tint for your linen shades, the black crayon will produce that in every degree, the paper answering for the lights of any-coloured drapery; for then you are to wash-in and shadow it with the crayons. Your paper is to be perfectly dry, otherwise the work will appear glazy; but even should that be the case, hold it before the fire, and the shining appearance will instantly vanish.

With respect to your back grounds, as this style of painting is intended to be light and sketchy, sky and back grounds are to be preferred; to manage which, the best way is to stump them in with dry colour, to whatever tint you find pleasing, which will give a proper value to the appearances of your wax crayons. Your drawing, either of portrait or landscape, being finished, have ready a large flat board, on which you are to stretch a sheet of royal paper; and having pasted the back of your drawing with some flour paste mixed with isinglass, lay it on the royal paper, and carefully press it in all directions with a soft towel or handkerchief, when your work is completed.

WAY. A way may be by prescription, as if the owners and occupiers of such a farm have immemorially used to cross another's ground; for this immemorial usage supplies an original grant. A right of way may also arise by act and operation of law; for if a man grants to another a piece of ground in the middle of his field, he at the same time tacitly gives him a way to come at it, for where the law gives any thing to any person, it gives implied whatever is necessary for enjoying the same. 2 Black. 35.

Way *of a ship*, is sometimes used for her wake or track. But more commonly the term is understood of the course or progress which she makes on the water under sail: thus when she begins her motion, she is said to be under way; when that motion increases, she is said to have fresh way through the water; when she goes apace, they say she has a good way; and the account of her rate of sailing by the log, they call, keeping an account of her way. And because most ships are apt to fall a little to the leeward of their true course, it is customary, in casting up the log-board, to allow something for her leeward way, or lee way. Hence also a ship is said to have head-way, and stern-way.

WAYGHTES, or Waits. This noun formerly signified hautboys; and, which is remarkable, has no singular number. From the instruments its signification was, after a time, transferred to the performers themselves; who being in the habit of parading the streets by night with their music, occasioned the name to be applied generally to all musicians who followed a similar practice. Hence those persons who annually, at the approach of Christmas, salute us with their nocturnal concerts, were, and are to this day, called wayghtes.

WAYWISER, an instrument for measuring the road, or distance travelled; called also Perambulator, and Pedometer. See those two articles.

Mr. Lovell Edgworth communicated to the Society of Arts, &c. an account of a way-wiser of his invention; for which he obtained a silver medal. This machine consists of a nave, formed of two round flat pieces of wood, one inch thick and eight inches in diameter. In each of the pieces there are cut eleven grooves, $\frac{5}{8}$ of an inch wide, and $\frac{3}{8}$ deep; and when the two pieces are screwed together, they enclose eleven spokes, forming a wheel of spokes, without a rim: the circumference of the wheel is exactly one pole; and the instrument may be easily taken to pieces, and put up in a small compass. On each of the spokes there is driven a ferule, to prevent them from wearing out; and in the centre of the nave, there is a square hole to receive an axle. Into this hole is inserted an iron or brass rod, which has the thread of a very fine screw worked upon it from one end to the other; upon this screw hangs a nut which, as the rod turns round with the wheel, advances towards the nave of the wheel or recedes from it. The nut does this, because it is prevented from turning round with the axle, by having its centre of gravity placed at some distance below the rod, so as always to hang perpendicularly like a plummet. Two sides of this screw are filed away flat, and have figures engraved upon them, to shew by the progressive motion of the nut, how many circumvolutions of the wheel and its axle have been made: on one side the divisions of miles and furlongs are in a direct order, and on the other side the same divisions are placed in a retrograde order.

If the person who uses this machine places it at his right-hand side, holding the axle loosely in his hands, and walks forward, the wheel will revolve, and the nut advance from the extremity of the rod towards the nave of the wheel. When two miles have been measured, it will have come close to the wheel. But to continue this measurement, nothing more is necessary than to place the wheel at the left hand of the operator; and the nut will, as he continues the course, recede from the axletree, till another space of two miles is measured.

It appears from the construction of this machine, that it operates like circular compasses; and does not, like the common wheel waywiser, measure the surface of every stone and molehill, &c. but passes over most of the obstacles it meets with, and measures the chords only, instead of the arcs of any curved surfaces upon which it rolls.

WEASEL. See VITERRA.

WEATHER. See METEROLOGY.

WEATHER-GLASSES, are instruments contrived to indicate the state or disposition of the atmosphere, and the various alterations in the weather: such are barometers, thermometers, hygrometers, &c.

WEAVERS. The wages of journeymen weavers in London are to be settled by the lord mayor, recorder, and aldermen. Masters giving more wages than is appointed, to forfeit 50*l.* and journeymen demanding, or combining to demand more, to forfeit 40*s.* or be imprisoned three months.

WEAVING-LOOM. See LOOM.

WEB, a tissue, or texture, formed of threads interwoven with each other; some whereof are extended in length, and called the warp; and others drawn across, and called the woof. See WARP, &c.

WEB, *spider's*, or *cobweb*. See ARANEA.

WEBERA, a genus of plants of the class and order pentandria monogynia. It is contorted; berry inferior, two-celled; cells one-seeded; stigma club-shaped; calyx five-cleft. There are three species, shrubs of the East Indies.

WEEVER. See TRACHINUS.

WEIGELIA, a genus of plants of the class and order pentandria monogynia. The calyx is five-leaved; corolla funnel-form; style from the base to the germ; stigma peltate; seed one. There are two species, shrubs of Japan.

WEIGH, WAY, or WEY, *waga*, a weight of cheese, wool, &c. containing 256 pounds avoirdupoise. Of corn, the weigh contains forty bushels; of barley or malt six quarters. In some places, as Essex, the weigh of cheese is 300 pounds.

WEIGHT, *gravity*, in physics, a quality in natural bodies whereby they tend downwards, towards the centre of the earth. Or weight may be defined in a less limited manner, to be a power inherent in all bodies whereby they tend to some common point, called the centre of gravity; and that with a greater or less velocity, as they are more or less dense, or as the medium they pass through is more or less rare.

In the common use of language, weight and gravity are considered as one and the same thing. Some authors, however, make a difference between them, and hold gravity only to express a nisus, or endeavour to descend, but weight an actual descent. But there is room for a better distinction. In effect, one may conceive gravity to be the quality as inherent in the body; and weight the same quality, exerting itself either against an obstacle, or otherwise. Hence, weight may be distinguished, like gravity, into absolute and specific. See GRAVITY.

Sir Isaac Newton demonstrates, that the weights of all bodies, at equal distances from the centre of the earth, are proportionable to the quantities of matter each contains Whence it follows, that the weights of bodies have not any dependance on their forms or textures, and that all spaces are not equally full of matter. Hence also it follows, that the weight of the same body is different on the surface of different parts of the earth, as its figure is not a sphere, but a spheroid.

WEIGHT, *pondus*, in mechanics, is any thing to be raised, sustained, or moved by a machine, or any thing that in any manner resists the motion to be produced.

WEIGHT, in commerce, denotes a body of a known weight, appointed to be put in the balance against other bodies, whose weight is required.

The security of commerce depending, in good measure, on the justness of weights, which are usually of lead, iron, or brass, most nations have taken care to prevent the falsification of them, by stamping or marking them by proper officers, after being adjusted by some original standard. Thus in England, the standard of weights is kept in the exchequer, by a particular officer, called the clerk of the market.

WEIGHTS *and* MEASURES, *regulation of.* This is a branch of the king's prerogative. For the public convenience, these ought to be universally the same throughout the nation, the better to reduce the prices of articles to equivalent values. But as weight and measure are things in their nature arbitrary and uncertain, it is necessary that they are reduced to some fixed rule or standard. It is, however, impossible to fix such a standard by any written law or oral proclamation; as no person can, by words only, give to another an adequate idea of a pound weight, or foot rule. It is therefore expedient to have recourse to some visible, palpable, material standard, by forming a comparison with which all weights and measures may be reduced to one uniform size. Such a standard was antiently kept at Winchester; and we find in the laws of king Edgar, near a century before the Conquest, an injunction that that measure should be observed throughout the realm.

Most nations have regulated the standard of measures of length from some parts of the human body; as the palm, the hand, the span, the foot, the cubit, the ell (ulna or arm), the pace, and the fathom. But as these are of different dimensions in men of different proportions, antient historians inform us, that a new standard of length was fixed by our king Henry the First; who commanded that the ulna, or antient ell, which answers to the modern yard, should be made of the exact length of his own arm.

A standard of long measure being once gained, all others are easily derived from it; those of greater length by multiplying that original standard, those of less by dividing it. Thus, by the statute called compositio ulnarum et perticarum, $5\frac{1}{2}$ yards make a perch; and the yard is subdivided into three feet, and each foot into twelve inches, which inches will be each of the length of three barleycorns. But some, on the contrary, derive all measures by composition, from the barleycorn.

Superficial measures are derived by squaring those of length: and measures of capacity by cubing them.

The standard of weights was originally taken from grains or corns of wheat, whence our lowest denomination of weights is still called a grain; thirty-two of which are directed, by the statute called compositio mensurarum, to compose a pennyweight, twenty of which make an ounce, and twelve ounces a pound, &c.

Under king Richard the First it was ordained, that there should be only one weight and one measure throughout the nation; and that the custody of the assize or standard of weights and measures, should be committed to certain persons in every city and borough; from whence the antient office of the king's ulnager seems to have been derived. These original standards were called pondus regis, and mensura domini regis, and are directed by a variety of subsequent statutes to be kept in the exchequer chamber, by an officer called the clerk of the market, except the wine gallon, which is committed to the city of London, and kept in Guildhall.

The Scottish standards are distributed among the oldest boroughs. The elward is kept at Edinburgh, the pint at Stirling, the pound at Lanark, and the firlot at Linlithgow.

The two principal weights established in Great Britain, are troy weight and avoirdupois weight, as before mentioned. Under the head of the former it may farther be added, that a carat is a weight of four grains; but when the term is applied to gold, it denotes the degree of fineness. Any quantity of gold is supposed divided into twenty-four parts. If the whole mass is pure gold, it is said to be twenty-four carats fine; if there are twenty-three parts of pure gold, and one part of alloy or base metal, it is said to be twenty-three carats fine, and so on.

Pure gold is too soft to be used for coin. The standard coin of this kingdom is 22 carats fine. A pound of standard gold is coined into $44\frac{1}{2}$ guineas, and therefore every guinea should weigh 5 dwts. $9\frac{39}{89}$ grains.

A pound of silver for coin contains 11 oz. 2 dwts. pure silver, and 18 dwts. alloy; and standard silver plate 11 ounces pure silver, with one ounce alloy. A pound of standard silver is coined into 62 shillings, and therefore the weight of a shilling should be 3 dwts. $20\frac{28}{31}$ grains.

WEIGHTS may be distinguished into antient and modern, foreign and domestic.

WEIGHTS, *Antient.* 1. Those of the antient Jews, reduced to the English troy weights, will stand as in the following table:

			lb.	oz.	dwt.	gr.
Shekel			00	00	09	$02\frac{4}{7}$
60	Maneh		02	03	06	$10\frac{2}{7}$
3000	50	Talent	113	10	01	$10\frac{2}{7}$

2. Grecian and Roman weights, reduced to English troy weight, will stand as in the following table:

										oz.	dwt.	gr.
Lentes										00	00	$\frac{85}{112}$
4	Siliquæ									00	00	$03\frac{1}{28}$
12	3	Obolus								00	00	$09\frac{3}{28}$
24	6	2	Scriptulum							00	00	$18\frac{3}{14}$
72	18	6	3	Drachma						00	02	$06\frac{9}{14}$
96	24	8	4	$1\frac{1}{3}$	Sextula					00	03	$00\frac{6}{7}$
144	56	12	6	2	$1\frac{1}{2}$	Sicilicus				00	04	$13\frac{2}{7}$
192	48	16	8	$2\frac{2}{3}$	2	$1\frac{1}{3}$	Duella			00	06	$01\frac{5}{7}$
576	144	48	24	8	6	4	3	Uncia		00	18	$05\frac{1}{7}$
6912	1728	576	288	96	72	48	36	12	Libra	10	18	$13\frac{5}{7}$

The Roman ounce is the English avoirdupois ounce, which they divided into seven denarii, as well as eight drachms: and since they reckoned their denarius equal to the Attic drachm, this will make the Attic weights one-eighth heavier than the corresponding Roman weights.

WEIGHTS, *Modern European.* 1. English weights: By the twenty-seventh chapter of Magna Charta, the weights all over England are to be the same; but for different commodities, there are two different sorts, viz. Troy weight and avoirdupois weight. The origin from which they are both raised, is a grain of weight gathered in the middle of the ear.

In troy weight, twenty-four of these grains make a pennyweight sterling; twenty pennyweights make one ounce; and twelve ounces one pound.

By this weight we weigh gold, silver, jewels, grains, and liquors. The apothecaries also use the troy pound, ounce, and grain; but they differ from the rest in the intermediate divisions. They divide the ounce into eight drachms; the drachm into three scruples, and the scruple into twenty grains.

In avoirdupois weight, the pound contains sixteen ounces, but the ounce is less by near one-twelfth than the troy ounce; this latter containing 490 grains, and the former only 448. The ounce contains 16 drachms: 80 ounces avoirdupois are only equal to 73 ounces troy; and 17 pounds troy equal to 14 pounds avoirdupois.

By avoirdupois weight are weighed mercury, and grocery wares, base metals, wool, tallow, hemp, drugs, bread, &c.

Table of Troy Weight as used by the Goldsmiths.

Grains.

860160	286720	35840	2240	20	Ton.

Mr. Ferguson gives the following comparison between troy and avoirdupois weight.

175 troy pounds are equal to 144 avoirdupois pounds.

175 troy ounces are equal to 192 avoirdupois ounces.

1 troy pound contains 5760 grains.

1 avoirdupois pound contains 7000 grains.

1 avoirdupois ounce contains $437\frac{1}{2}$ grains.

1 avoirdupois dram contains 27.34375 grains.

1 troy pound contains 13 oz. 2.651428576 drams avoirdupois.

1 avoirdupois lb. contains 1 lb. 2 oz. 11 dwts. 16 gr. troy.

Therefore the avoirdupois lb. is to the lb. troy as 175 to 144, and the avoirdupoise oz. is to the troy oz. as $437\frac{1}{2}$ is to 480

The moneyers, jewellers, &c. have a particular class of weights for gold and precious stones, viz. *carat* and *grain*; and for silver, the *pennyweight* and *grain*. The moneyers have also a peculiar subdivision of the troy grain: thus, dividing

the grain into 20 mites,
the mite into 24 droits,
the droit into 20 periots,
the periot into 24 blanks.

The dealers in wool have likewise a particular set of weights; viz. the *sack, weigh, tod, stone,* and *clove*; the proportions of which are as below; viz.

the sack containing 2 weighs,
the weigh - - - $6\frac{1}{2}$ tods,
the tod - - - - 2 stones,
the stone - - - 2 cloves,
the clove - - - 7 pounds.

Also 12 sacks make a last, or 4368 pounds.

Farther,

56 lb. of old hay, or 60 lb. new hay, make a truss.

40 lb. of straw make a truss.

36 trusses make a load, of hay or straw.

14 lb. make a stone.

5 lb. of glass a stone.

Other nations have also certain weights peculiar to themselves: thus, Spain has its arrobas, containing 25 Spanish pounds, or one-fourth of the common quintal: its quintal macho, containing 150 pounds, or one-half common quintal, or 6 arrobas: its adarme, containing one-sixteenth of its ounce. And for gold, it has its castillan, or one-hundredth of a pound; and its tomin, containing 12 grains, or one-eighth of a castillan. The same are in use in the Spanish West Indies.

Portugal has its arroba, containing 32 Lisbon arratals, or pounds: Savary also mentions its faratelle, containing 2 Lisbon pounds; and its rottolis, containing about 12 pounds. And for gold, its chego, containing four carats. The same are used in the Portuguese East Indies.

Italy, and particularly Venice, have their migliaro, containing four mirres; the mirre containing 30 Venice pounds: the saggio, containing a sixth part of an ounce. Genoa has five kinds of weights, viz. large weights, whereby all merchandizes are weighed at the custom-house; cash weights for piastres, and other specie; the cantara, or quintal, for the coarsest commodities; the large balance for raw silks, and the small balance for the fine commodities. Sicily has its rottolo, 32 and a half pounds of Messina. Germany, Flanders, Holland, the Hanse towns, Sweden, Denmark, Poland, &c. have their schippondt, which at Antwerp and Hamburgh, is 300 pounds; at Lubeck, 320 and at Coningsberg, 400 pounds. In Sweden, the schippondt for copper is 320 pounds; and the schippondt for provisions 400 pounds. At Riga and Revel, the schippondt is 400 pounds; at Dantzic, 340 pounds; in Norway, 300 pounds: at Amsterdam, 300; containing 20 lyspondts, each weighing 15 pounds.

In Muscovy, they weigh their large commodities by the bercheroct, or berkewits, containing 400 of their pounds They have also the poet, or poede, containing 40 pounds, or one-tenth of the bercheroct.

In order to shew the proportion of the several weights used throughout Europe, we shall add a reduction of them to one standard, viz. the London and Amsterdam pound.

1. Proportion of the weights of the principal places of Europe.

The 100 lb. of England, Scotland, and Ireland, are equal to

lb.	oz.	
91	8	of Amsterdam, Paris, &c.
96	8	of Antwerp or Brabant.
88	0	of Rouen, the viscounty weight.
106	0	of Lyons, the city weight.
90	9	of Rochelle.
107	11	of Toulouse and Upper Languedoc.
113	0	of Marseilles or Provence.
81	7	of Geneva.
93	5	of Hamburgh.
89	7	of Francfort, &c.
96	1	of Leipsick, &c.
137	4	of Genoa.
132	1	of Leghorn.
153	11	of Milan.
152	0	of Venice.
154	10	of Naples.
97	0	of Seville, Cadiz, &c.
104	13	of Portugal.
96	5	of Liege.
112	$\frac{2}{3}$	of Russia.
107	$\frac{1}{24}$	of Sweden.
89	$\frac{1}{2}$	of Denmark.

2. Proportion of the weights of the chief cities in Europe, to those of Amsterdam.

100 pounds of Amsterdam are equal to

lb.		lb.	
108	of Alicant.	$113\frac{1}{2}$	of Dantzic.
105	of Antwerp.	100	of Dort.
120	of Archangel, or 3 poedes.	97	of Dublin.
105	of Arschot.	97	of Edinburgh.
120	of Avignon.	143	of Florence.
98	of Basil in Switzerland.	98	Francfort on the Maine.
100	of Bayonne in France.	105	of Gaunt.
166	of Bergamo.	89	of Geneva.
97	of Bergen-op-zom.	163	of Genoa, cash-weight.
$95\frac{1}{4}$	of Bergen in Norway.	102	of Hamburgh.
111	of Bern.	106	of Leyden.
100	of Besançon.	105	of Leipsic.
100	of Bilboa.	105 $\frac{1}{2}$	of Liege.
105	of Bois le duc.	114	of Lisle.
151	of Bologna.	143	of Leghorn.
100	of Bourdeaux.	106 $\frac{1}{2}$	of Lisbon.
104	of Bourg en Bresse.	109	of London, avoirdupois weight.
103	of Bremen.	105	of Lovaine.
125	of Breslaw.	105	of Lubec.
105	of Bruges.	141 $\frac{1}{2}$	of Lucca, light weight.
105	of Brussels.	116	of Lyons, city do.
105	of Cadiz.	114	of Madrid.
105	of Cologne.	105	of Marlines.
125	of Coningsberg.	123 $\frac{1}{2}$	of Marseilles.
$107\frac{1}{2}$	of Copenhagen.	154	of Messina, light weight
87	rottos of Constantinople.	168	of Milan.

lb.		lb.	
120	of Montpelier.	96	of Rouen, viscounty weight.
125	bercheroctsof Muscovy.	100	of St. Malo.
100	of Nantes.	100	of St. Sebastian.
106	of Nancy.	158½	of Saragossa.
169	of Naples.	106	of Seville.
98	of Nuremberg.	114	of Smyrna.
100	of Paris.	110	of Stetin.
112½	of Revel.	81	of Tholouse and Upper Languedoc.
109	of Riga.	151	of Turin.
100	of Rochelle.	158 ¼	of Valencia.
146	of Rome.	182	of Venice, small weight.
100	of Rotterdam.		

We shall now notice the correspondence between English weights and some modern weights in France and other countries:

English Weights.

Troy Weight.

lb.	*oz.*	*drms.*	*scruples.*	*grains.*	*grammes.*
1 =	12 =	96 =	288 =	5760 =	372.96
	1 =	8 =	24	480 =	31.08
		1 =	3 =	60 =	3.885
			1 =	20 =	1.395
				1 =	0.06475

Avoirdupois Weight.

lb.	*oz.*	*drms.*	*grains.*	*grammes.*
1	16 =	256 =	7000 =	453.25
	1 =	16 =	437.5 =	28.32
		1	27.975 =	1.81

German.

71 lbs. or grs. English troy, = 74 lbs. or grs. German apothecaries' weight.

1 oz. Nuremberg, medic. weight, = 7 dr. 2 sc. 9 grains English.

1 mark Cologne, = 7 oz. 2 dwt. 4 gr. English troy.

Dutch.

1 lb. Dutch, = 1 lb. 3 oz. 16 dwt. 7 gr. English troy.

787½ lbs. Dutch, = 1038 lbs. English troy.

Swedish Weights, *used by Bergman and Scheele.*

The Swedish pound, which is divided like the English apothecary, or troy, pound, weighs 6556 grains troy.

The kanne of pure water, according to Bergman, weighs 42250 Swedish grains, and occupies 100 Swedish cubical inches. Hence the kanne of pure water weighs 48088.719444 English troy grains, or is equal to 189.9413 English cubic inches; and the Swedish longitudinal inch is equal to 1.238435 English longitudinal inches.

From these data, the following rules are deduced:

1. To reduce Swedish longitudinal inches to English, multiply by 1.2384, or divide by 0.80747.
2. To reduce Swedish to English cubical inches, multiply by 1.9, or divide by 0.5265.
3. To reduce the Swedish pound, ounce, dram, scruple, or grain, to the corresponding English troy denomination, multiply by 1.1382, or divide by 8.786.
4. To reduce the Swedish kannes to English wine pints, multiply by .1520207, or divide by 6.57804.
5. The lod, a weight sometimes used by Bergman, is the 32d part of the Swedish pound: Therefore, to reduce it to the English troy pound, multiply by .03557, or divide by 28.1156.

Correspondence of English Weights with those used in France before the Revolution.

The Paris pound, poids de marc of Charlemagne, contains 9216 Paris grains; it is divided into 16 ounces, each ounce into 8 gros, and each gros into 72 grains. It is equal to 7561 English troy grains.

The English troy pound of 12 ounces contains 5760 English troy grains, and is equal to 7021 Paris grains.

The English avoirdupois pound of 16 ounces contains 7000 English troy grains, and is equal to 85 , Paris grains.

To reduce Paris grains to English troy grains, divide by - - To reduce English troy grains to Paris grains, multiply by - -	1.2189
To reduce Paris ounces to English troy, divide by - - - To reduce English troy ounces to Paris, multiply by - -	1.015734

Or the conversion may be made by means of the following tables:

I. *To reduce French to English Troy Weight.*

The Paris pound	= 7561	English troy grains.
The ounce	= 472.5625	
The gros	= 59.0703	
The grain	= .8204	

II. *To reduce English troy to Paris weight.*

The English troy pound of 12 ounces - -	= 7021.	Paris grains.
The troy ounce - -	= 585.0893	
The dram of 60 grains -	= 73.1354	
The pennyweight, or denier, of 24 grains -	= 29.2541	
The scruple of 20 grains -	= 24.3784	
The grain - - - -	= 1.2189	

III. *To reduce English avoirdupois to Paris weight.*

The avoirdupois pound of 16 ounces, or 7000 troy grains - - -	= 8538.	Paris grs.
The ounce - - - -	= 533.6250	

Table, *shewing the Comparison between French and English Grains.* (*Poid de Marc.*)

French grs.	= Eng. grs.	Eng. grs.	= French grs.
1	0.8203	1	1.2189
2	1.6407	2	2.4378

Weights *used in the several parts of Asia, the East Indies, China, Persia,* &c. In Turkey, at Smyrna, &c. they use the batman, or battemant, containing six occos, the occo weighing three pounds four-fifths English. They have another batman much less, consisting, as the former, of six occos; but the occo only containing fifteen ounces English; 44 occos of the first kind make the Turkish quintal. At Cairo, Alexandretta, Aleppo, and Alexandria, they use the rotto, rotton, or rottoli; at Cairo, and other parts of Egypt, it is 144 drachms, being somewhat over an English pound. At Aleppo there are three sorts of rottos; the first 720 drachms, making about seven pounds English, and serving to weigh cottons, galls, and other large commodities; the second is 624 drachms, used for all silks but white ones, which are weighed by the third rotto of 700 drachms. At Seyda the rotto is 600 drachms.

The other ports of the Levant, not named here, use some of these weights, particularly the occo, or ocqua, the rottoli, and rotto.

The Chinese weights are the piece, for large commodities; it is divided into 100 catis, or cattis, though some say into 125; the cati into 16 taels, or tales, each tale equivalent to 1⅓ of an ounce English, or the weight of one rial and $\frac{1}{12}$, and containing 12 mas, or masses, and each mas 10 condrins. So that the Chinese piece amounts to 137 pounds English avoirdupois, and the cadi to 1 pound 8 ounces. The picol for silk contains 66 catis and ¾: the bahar, bakaire, or barr, contains 300 catis.

Tonquin has also the same weights, measures, &c. as China. Japan has only one weight, viz. the cati, which, however, is different from that of China, as containing 20 taels. At Surat, Agra, and throughout the states of the Great Mogul, they use the man, or maund, whereof they have two kinds, the king's man, or king's weight, and the man simply; the first used for the weighing of common provisions, containing 40 seers, or seres, and each seer a just Paris pound. The common man, used in the weighing of merchandise, consists likewise of 40 seers, but each seer is only estimated at 12 Paris ounces, or ¾ of the other seer.

The man may be looked on as the common weight of the East Indies, though under some difference of name, or rather of pronunciation, it being called mao at Cambaya, and in other places mein, and maun. The seer is properly the Indian pound, and of universal use; the like may be said of the bahar, tael, and catti above-mentioned.

The weights of Siam are the piece containing two shans, or cattis; but the Siamese catti is only half the Japanese, the latter containing 20 taels; and the former only 10; though some make the Chinese catti only 16 taels, and the Siamese 8. The tael contains 4 baats or ticals, each about a Paris ounce; the baat 4 selings, or mayons; the mayon 2 fouangs; the fouang 4 payes; the paye 2 clams; the sompaye half a fouang.

It is to be observed, that these are the names of their coins as well as weights; silver and gold being commodities there sold, as other things, by their weights.

In the isle of Java, and particularly at Bantam, they use the gantan, which amounts to near three Dutch pounds. In Golconda, at Visapour, and Goa, they have the furatelle containing 1 pound 14 ounces English; the mangalis or mangelin for weighing diamonds and precious stones, weighing at Goa 5 grains, at Golconda, &c. $5\frac{1}{2}$ grains. They have also the rotolo containing $14\frac{1}{4}$ ounces English; the metricol containing the sixth part of an ounce; the wall for piasters and ducats, containing the 73d part of a rial.

In Persia they use two kinds of batmans or mans, the one called cahi or cheray, which is the king's weight; and the other batman of Tauris. The first weighs 13 pounds 10 oz. English; the second $6\frac{1}{2}$ pounds, Its divisions are the ratel, or a 16th; the derhem, or drachm. which is the 50th; the meschal, which is half the derhem; the dung, which is the 6th part of the meschal, being equivalent to six carat-grains; and, lastly, the grain, which is the fourth part of the dung. They have also the vakie, which exceeds a little our ounce; the sah-cheray, equal to the 1170th part of the derhem; and the toman, used to weigh out large payments of money without telling; its weight is that of 50 abassis.

African and American weights. We have little to say as to the weights of America; the several European colonies there making use of the weights of the states or kingdoms of Europe they belong to. For, as to the aroue of Peru, which weighs 27 pounds, it is evidently no other than the Spanish arroba, with a little difference in the name.

As to the weights of Africa, there are few places that have any, except Egypt, and the countries bordering on the Mediterranean, whose weights have been already enumerated among those of the ports of the Levant. The island of Madagascar indeed has weights, but none that exceed the drachm, nor are they used for any thing but gold and silver.

Weights *and* Measures. The standard of measures was originally kept at Winchester, which measure was by the law of king Edgar, ordained to be observed through the kingdom.

By. stat. 35 G. III. c. 102, the justices in quarter-sessions in every county, are required to appoint persons to examine the weights and balances within their respective jurisdictions. These inspectors may seize and examine weights in shops, &c. and seize false weights and balances, and the offender, being convicted before one justice, shall be fined from 5*s*. to 20*s*. Persons obstructing the inspectors to forfeit from 5*s*. to 40*s*. Inspectors to be recompensed out of the county-rate. Standard weights to be purchased by the sessions out of the county-rate, and produced to all persons paying for the production thereof. Informations to be within one month.

Universal standard for weights and measures. Philosophers, from their habits of generalizing, have often made speculations for forming a general standard for weights and measures through the whole world. These have been devised chiefly of a philosophical nature, as best adapted to universality. After the invention of pendulum clocks, it first occurred that the length of a pendulum which should vibrate seconds, would be proper to be made a universal standard for length; whether it should be called a yard, or any thing else. But it was found that it would be difficult in practice, to measure and determine the true length of such a pendulum, that is, the distance between the point of suspension and the point of oscillation. Another cause of inaccuracy was afterwards discovered, when it was found that the seconds pendulum was of different lengths in all the different latitudes, owing to the spheroidal figure of the earth; which causes that all places in different latitudes are at different distances from the centre, and consequently the pendulums are acted upon by different forces of gravity, and therefore require to be of different lengths. In the latitude of London this is found to be $39\frac{1}{8}$ inches.

The Society of Arts of London, among their many laudable patriotic endeavours, offered a handsome premium for the discovery of a proper standard for weights and measures. This brought them many frivolous expedients, as well as one which was an improvement on the method of the pendulum, by Mr. Hatton. This consisted in measuring the difference of the lengths of two pendulums of different times of vibration, which could be performed more easily and accurately than that of the length of one single pendulum. This method was put in practice, and fully explained and illustrated, by the late Mr. Whitehurst, in his attempt to ascertain an universal standard of weights and measures. But still the same kind of inaccuracy of measurement, &c. obtains in this way, as in the single pendulum, though in a smaller degree.

Another method that has been proposed for this purpose is the space that a heavy body falls freely through in one second of time. But this is an experiment more difficult than the former to be made with accuracy, on which account different persons will all make the space fallen to be of different quantities, which would give as many different standards of length. Add to this, that the spheroidal form of the earth here again introduces a diversity in the space, owing to the different distances from the centre, and the consequent diversity in the force of gravity by which the body falls. This space has been found to be 193 inches, or $16\frac{1}{12}$ feet, in the latitude of London; but it will be a different quantity in other latitudes.

Many other inferior expedients have also been proposed for the purpose of universal measures and weights; but there is another which now has the best prospect of success, and is at present under particular experiments, by the philosophers both of this and the French nation. This method is by the measure of the degrees of latitude, which would give a large quantity, and admit of more accurate measure, by subdivision, than what could be obtained by beginning from a small quantity, or measure, and thence to proceed increasing by multiples. This measure might be taken either from the extent of the whole compass of the earth, or of all the 360 degrees, or a medium degree among them all, or from the measure of a degree in the medium latitude of 45 degrees. It will also be most convenient to make the subdivisions of this measure, when found, to proceed decimally, or continually by 10ths.

The universal standard for lengths being once established, those of weights, &c. would easily follow. For instance: a vessel, of certain dimensions, being filled with distilled water, or some other homogeneous matter, the weight of that may be considered as a standard for weights.

WEINMENNIA, a genus of plants of the class and order octandria digynia. The calyx is four-leaved; corolla four-petalled; caps. two-celled, two-beaked. There are six species, trees of the southern climates.

WELDING HEAT, in smithery, a degree of heat given to iron, &c. sufficient to make any two bars or pieces of iron unite by a few strokes of the hammer, and form one piece. See Iron.

WEN. See Surgery.

WESTRINGIA, a genus of plants of the didynamia gymnospermia class and order. The calyx is half five-cleft, five-sided; corolla reversed; four segments, longest erect; cloven stam. distant, two shorter abortive. There is one species, a shrub of New South Wales.

WHALE. See Balæna.

WHEAT. See Triticum, and Husbandry.

Wheat-ear. See Motacilla.

WHEEL, in mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on an axis. The wheel is one of the principal mechanic powers; it has place in most engines; in effect, it is of an assemblage of wheels that most of our engines are composed. See Mechanics.

Wheels, *of coaches, carts, waggons, &c.* With respect to wheels of carriages, the following particulars are collected from the experiments and observations of Desaguliers, Beighton, Camus, Ferguson, Jacob, &c.

1. The use of wheels in carriages is twofold, viz. that of diminishing or more easily overcoming the resistance or friction from the carriage; and that of more easily overcoming obstacles in the road. In the first case, the friction on the ground is transferred in some degree from the outer surface of the wheel to its nave and axle; and in the latter, they serve easily to raise the carriage over obstacles and asperities met with on the roads. In both these cases, the height of the wheel is of material consideration, as the spokes act as levers, the top of an obstacle being the fulcrum, their length enables the carriage more easily to surmount them; and the greater proportion of the wheel to the axle serves more easily to diminish or to overcome the friction of the axle.

2. The wheels should be exactly round; and the fellies at right angles to the naves, according to the inclination of the spokes.

3. It is the most general opinion, that the spokes are somewhat inclined to the naves, so that the wheels may be dishing or concave. Indeed if the wheels were always to roll upon smooth and level ground, it would be best to make the spokes perpendicular to the naves, or to the axles; because they would then bear the weight of the load perpendicularly. But because the ground is commonly uneven, one wheel often falls into a cavity or rut, when the other does not, and then it bears much more of the weight than the other does;

in which case it is thought best for the wheel to be dished, because the spokes become perpendicular in the rut, and therefore have the greatest strength when the obliquity of the road throws most of the weight upon them; whilst those on the high ground have less weight to bear, and therefore need not be at their full strength.

4. The axles of the wheels should be quite straight, and perpendicular to the shafts, or to the pole. When the axles are straight, the rims of the wheels will be parallel to each other, in which case they will move the easiest, because they will be at liberty to proceed straight forwards. But in the usual way of practice, the ends of the axles are bent downwards, which always keeps the sides of the wheels that are next the ground nearer to one another than their upper sides are; and this not only makes the wheels drag sideways as they go along, and gives the load a much greater power of crushing them than when they are parallel to each other, but also endangers the overturning the carriage when a wheel falls into a hole or rut, or when the carriage goes on a road that has one side lower than the other, as along the side of a hill.

5. Large wheels are found more advantageous for rolling than small ones, both with regard to their power as a longer lever, and to the degree of friction, and to the advantage in getting over holes, rubs, and stones, &c. If we consider wheels with regard to the friction upon their axles, it is evident that small wheels, by turning oftener round, and swifter about the axles, than large ones, must have more friction. Again, if we consider wheels as they sink into holes or soft earth, the large wheels, by sinking less, must be more easily drawn out of them, as well as over stones and obstacles, from their greater length of lever or spokes.

It is a fact, however, that the draught ought not to be horizontal, but rather inclined: because in the horizontal draught the collar presses against the chest of the horse, instead of bearing on his shoulders, as in an inclined draught; and because in this latter circumstance the wheels pass more easily over obstacles than when the draught is horizontal. Hence it appears, that wheels are the more advantageous as they are larger, provided they are not so high as to make the draught horizontal; and when they are very large also, they become too heavy; or if they are made light, their strength is proportionably diminished, and the length of the spokes renders them more liable to break; besides, horses applied to such wheels would not be capable of exerting their utmost strength, for the reasons already assigned, small wheels occasioning the horses to draw upwards.

6. Carriages with four wheels, as waggons or coaches, are much more advantageous than carriages with two wheels, as carts and chaises: for with two wheels it is plain the tiller-horse carries part of the weight, in one way or other; in going down hill, the weight bears upon the horse; and in going up hill, the weight falls the other way, and lifts the horse, which is still worse. Besides, as the wheels sink into the holes in the roads, sometimes on one side, sometimes on the other, the shafts strike against the tiller's sides, which destroys many horses: moreover, when one of the wheels sinks into a hole or rut, half the weight falls that way, which endangers the overturning of the carriage.

7. It would be much more advantageous to make the four wheels of a coach or waggon nearly of a height, than to make the fore-wheels of only half the diameter of the hind-wheels, as is used in many places. The fore-wheels have commonly been made of a less size than the hind ones, both on account of turning short, and to avoid cutting the braces. Crane-necks have also been invented for turning yet shorter; and the fore-wheels have been lowered, so as to go quite under the bend of the crane-neck.

When a horse draws hard, it is observed that he bends forward, and brings his breast near the ground, and then if the wheels are high, he is pulling the carriage against the ground. A horse tackled in a waggon will draw two or three ton, because the point or line of traction is below his breast, by the lowness of the wheels. It is also common to see, when one horse is drawing a heavy load, especially up hill, his fore-feet will rise from the ground; in which case it is usual to add a weight on his back, to keep his fore-part down, by a person mounting on his back or shoulders, which will enable him to draw that load which he could not move before. The greatest stress, or main business of drawing, is to overcome obstacles; for on level plains the drawing is but little, and then the horse's back need be pressed but with a small weight.

8. The utility of broad wheels, in amending and preserving the roads, has been so generally believed, as to have occasioned the legislature to enforce their use. At the same time, the proprietors and drivers of carriages seem to be convinced by experience, that a narrow-wheeled carriage is more easily and speedily drawn by the same number of horses, than a broad-wheeled one of the same burthen; probably because they are much lighter, and have less friction on the axle; and the owners of broad-wheeled waggons contrive in general to make them as destructive to roads as narrow-wheeled ones, by making the rim of the wheel of unequal diameters, and the waggon consequently to go generally on a sharp and narrow edge.

Wheel-animals, *brachionus*, a genus of animalcules which have an apparatus of arms for taking their prey. This apparatus has been supposed, by microscopical writers, to be a kind of wheels; and they thence named the creatures that are possessed of it, wheel-animals.

WHIRLPOOL, an eddy, vortex, or gulph, where the water is continually turning round. These in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine whirlpool among the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea among those islands. Wherever it appears, it is very furious; and boats, &c. would inevitably be drawn in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing, in the boat with them; as soon as they perceive the whirlpool, they toss this within its vortex, keeping themselves out; this substance, whatever it may be, is immediately received into the centre, and carried under water; and as soon as this is done, the surface of the place where the whirlpool was becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place, usually at about a mile distance from the first.

WHIRLWIND. This phenomenon is well defined by its name. Its nature may be illustrated by recurring to the same kind of motion in a denser fluid. When water is flowing through an aperture in the bottom of a vessel, we may observe that the meeting of the currents which proceed from all sides towards the opening, gives rise at length to a circular motion just over it; at first confined to a small space, but spreading by degrees, until it occupies a large portion of the surrounding water. At this time, the centrifugal force becoming greater every instant, the water absolutely quits the central space, leaving a hole through it, which, together with the whirling motion, continues during the remaining time of the discharge. Now, as the water descends by its gravity, and the other effect depends on a lateral impulse, given by the most powerful of the confluent streams, so the heated air, over some particular tract, ascending by the lateral pressure of surrounding colder and heavier air, may at any time give rise to a whirlwind of greater or less extent and force, according to the quantity of air required to be thus transmitted to a higher station, in order that the equilibrium of the atmosphere may be restored. There is wanted for this purpose only a sudden impulse from some quarter, sufficient to disturb the uniform motion of the ascending stream. The effects of whirlwinds are sometimes tremendous; not only large quantities of hay, and other light bodies, but even the limbs of trees, the roofs of houses, and other ponderous matters, having been lifted up and carried off by them. Their effects are no where more conspicuous than in the vast pillars of sand, so much dreaded by travellers, which they raise from the moveable surface of the deserts in the East, and of which we have a good account in Bruce's Travels. Dr. Franklin, in whom sagacity of observation was eminently united with the power of simple and plain description, has left us the following account of a moderate whirlwind, of which he was an eye-witness close at hand.

"Being in Maryland (says the doctor) riding with colonel Parker, and some other gentlemen, to his country-seat, we saw in the vale below us a small whirlwind, beginning in the road, and shewing itself by the dust it raised and contained: it appeared in the form of a sugar-loaf, spinning on its point, moving up the hill towards us, enlarging as it came forward. When it passed by us, its smaller part, near the ground, appeared no bigger than a common barrel, but widening upwards, it seemed at 40 or 50 feet high, to be 20 or 30 feet in diameter. The rest of the company stood looking after it, but my curiosity being stronger, I followed it, riding close by its side, and observed it licking up, in its progress, all the dust that was under its smaller part. As it is a common opinion, that a shot fired through a water-spout will break it, I tried to break this little whirlwind, by striking my whip frequently through it, but without any effect. Soon after it quitted the road, and took into the woods, growing every moment larger and stronger, raising, instead of dust, the old dry leaves, with which the ground was thick-covered, and making a great noise with them and the branches of trees, bending some tall trees round in a circle swiftly, and very surprisingly; though the progressive motion of the whirl was not so swift, but that a man on foot might have kept pace with it; but the circular motion was amazingly rapid. By the leaves it was now filled with, I could plainly perceive that the current of air they were driven by, moved upwards in a spiral line; and when I saw the passing whirl continue entire after leaving the trunks and bodies of large trees which it had enveloped, I no longer wondered that my whip had no effect on it in its smaller state. I accompanied it about ¾ of a mile, till some limbs of dead trees, broken off by the whirl, flying about, falling near me, made me more apprehensive of danger; and then I stopped, looking at the top of it, as it went on, which was visible, by means of the leaves contained in it, for a very great height above the trees. Many of the leaves, as they got loose from the upper and widest part, were scattered in the wind; but so great was their height in the air, that they appeared no bigger than flies. My son, who by this time was come up with me, followed the whirlwind till it left the woods, and crossed an old tobacco field, where, finding neither dust nor leaves to take up, it gradually became invisible below, as it went away over that field. The course of the general wind then blowing was along with us as we travelled; and the progressive motion of the whirlwind was in a direction nearly opposite, though it did not keep a straight line; nor was its progressive motion uniform, it making little sallies as it went on either side, proceeding sometimes faster and sometimes slower, and seeming sometimes, for a few seconds, stationary; then starting forwards pretty fast again. When we rejoined the company again, they were admiring the vast height of the leaves now brought by the common wind over our heads. These leaves accompanied us as we travelled, some falling now and then round about us, and some not reaching the ground till we had gone near three miles from the place where we saw the whirlwind begin.

WHISPERING-PLACES depend upon this principle: If the vibrations of the tremulous body are propagated through a long tube, they will be continually reverberated from the sides of the tube into its axis, and by that means prevented from spreading, till they get out of it; whereby they will be exceedingly increased, and the sound rendered much louder than it would otherwise be. See Sound.

Hence it is, that sound is conveyed from one side of a whispering-gallery to the opposite one, without being perceived by those who stand in the middle. The form of a whispering-gallery is that of a segment of a sphere, or a similar arched figure.

WHIST, a well-known game at cards, which requires great attention and silence; hence the name. This game is played by four persons, who cut for partners; the two highest and the two lowest are together, and the partners sit opposite to each other; the person who cuts the lowest card is to deal first, giving one at a time to each person, till he comes to the last card, which is turned up for the trump, and remains on the table till each person has played a card. The person on the left-hand side of the dealer plays first, and whoever wins the trick is to play again, thus going on till the cards are played out. The ace, king, queen, and knave, of trumps, are called honours; in case any three of these honours have been played between, or by either of the two partners, they reckon for two points towards the game; and if the four honours have been played between or by either of the two partners, they reckon for four points towards the game, the game consisting of ten points. The honours are reckoned after the tricks; all above six tricks reckoning also towards the game.

In Hoyle's Games may be seen the general rules for playing whist, which are too long for insertion here.

WHITING. See Gadus.

WICKLIFFISTS, or Wickliffites, a religious sect which sprung up in England in the reign of Edward III. and took its name from John Wickliff, doctor and professor of divinity in the university of Oxford, who maintained that the substance of the sacramental bread and wine remained unaltered after consecration; and opposed the doctrine of purgatory, indulgences, auricular confession, the invocation of saints, and the worship of images. He maintained that children may be saved without being baptised; that priests may administer confirmation; that there ought to be only two orders in the church, that of priests, and that of deacons. He made an English version of the Bible, and composed two volumes, called Alethia, that is, Truth, from which John Husse learned most of his doctrines. In short, to this reformer we owe the first hint of the reformation which was effected about two hundred years after.

WIDOW, a woman who has lost her husband by death. In London, and throughout the province of York, the widow of a freeman, is by custom entitled to her apparel, and the furniture of the bed-chamber, called the widow's chamber.

WIFE. After marriage, all the will of the wife, in judgment of law, is subject to the will of the husband, and it is commonly said a feme covert has no will. See Husband and Wife.

WILDERNESS, in gardening, a kind of grove of large trees, in a spacious garden, in which the walks are commonly made either to intersect each other in angles, or have the appearance of meanders and labyrinths.

Wildernesses, says Mr. Miller, should always be proportioned to the extent of the gardens in which they are made; for it is very ridiculous to see a large wilderness planted with tall trees in a small spot of ground; and, on the other hand, nothing can be more absurd, than to see little paltry squares, or quarters of wilderness-work, in a magnificent large garden. As to the situation of wildernesses, they should never be placed too near the habitation, nor so as to obstruct any distant prospect of the country, there being nothing so agreeable as an unconfined prospect; but where, from the situation of the place, the sight is confined within the limits of the garden, or there is any thing unsightly to be concealed, nothing can so agreeably terminate the prospect as a beautiful scene of the various kinds of trees judiciously planted; and if it is so contrived, that the termination is planted circularly, with the concave towards the sight, it will have a much better effect, than if it ends in straight lines or angles. The plants should always be adapted to the size of the plantation; for it is very absurd for tall trees to be planted in the small squares of a little garden; and in large designs small shrubs will have a mean appearance.

As to the walks, those that have the appearance of meanders, where the eye cannot discover more than twenty or thirty yards in length, are generally preferable to all others, and these should now and then lead into an open circular piece of grass; in the centre of which may be placed either an obelisk, statue, or fountain; and, if in the middle of the wilderness there is contrived a large opening, in the centre of which may be erected a dome or banqueting-house, surrounded with a green plot of grass, it will be a considerable addition to the beauty of the whole. From the sides of the walks and openings, the trees should rise gradually one above another to the middle of the quarters, where should always be planted the largest-growing trees, so that the heads of all the trees may appear to view, while their stems will be hid from the sight. Thus those parts which are planted with deciduous trees, roses, honey-suckles, spiræas, and other kinds of low-flowering shrubs, may be planted next the walks and openings, and at their feet, near the sides of the walks, with primroses, violets, daffodils, &c. not in a straight line, but so as to appear accidental, as in a natural wood. Behind the first row of shrubs should be planted syringas, hibisrus, mezereons, and other flowering shrubs of a middle growth; and these may be backed with many other sorts of trees, rising gradually to the middle of the quarters.

The part planted with evergreens may be disposed in the following manner, viz. In the first line next the great walks, may be placed the laurustinus, boxes, spurge-laurel, juniper, savin, and other dwarf evergreens. Behind these may be placed laurels, hollies, arbutuses, and other evergreens of a larger growth. Next to these may be planted alaternuses, phyllireas, yews, cypresses, Virginian cedars, and other trees of the same growth; behind these may be planted Norway and silver firs, the true pine, and other sorts of the fir growth; and in the middle should be planted Scotch pines, pinaster, and other of the larger-growing evergreens, which will afford a most delightful prospect, if the different shades of the greens are curiously intermixed.

But beside the grand walks and openings, there should be some smaller walks through the middle of the quarters, where persons may retire for privacy; and by the sides of those private walks may also be scattered some wood flowers and plants, which, if artfully planted, will have a very good effect.

In the general design for these wildernesses, there should not be a studied and stiff correspondency between the several parts; for the greater diversity there is in the distribution of these, the more pleasure they will afford.

WILL AND TESTAMENT, in law. Every person capable of binding himself by contract, is capable of making a will.

Also a male infant of the age of 14 years and upwards, and female of 12 years and upwards, are capable of making a will respecting personal estates only.

But a married woman cannot make a will unless a power is reserved in a marriage settlement; but wherever personal property, however, is given to a married woman for her sole and separate use, she may dispose of it by will.

If a feme sole makes her will, and afterwards marries, such marriage is a legal revocation of the will.

Wills are of two kinds, written and verbal; the former are most usual and secure.

It is not absolutely necessary that a will should be witnessed; and a testament of chattles, written in the testator's own hand, though it should have neither the testator's name nor seal to it, nor witnesses present at his publication, will be good, provided sufficient proof can be had that it is his hand-writing. Gilb. 260.

By stat. 29 Car. II. c. 3, all devises of lands, and tenements, shall not only be in writing, but shall also be signed by the party so devising the same, or by some other person in his presence, and by his express direction, and shall be witnessed and subscribed in the presence of the person devising, by three or four credible witnesses, or else the devise will be entirely void, and the land will descend to the heir at law.

A will, even if made beyond sea, bequeathing land in England, must be attested by three witnesses. 2 Pere Wms. 293.

A will, however, devising copyhold land, does not require to be witnessed: it is sufficient to declare the uses of a surrender of such copyhold land made to the use of the will. The party to whom the land is given becomes entitled to it by means of the surrender, and not by the will. 2 Atk. 37.

A codicil is a supplement to a will, or an addition made by the person making the same, annexed to, and to be taken as part of, the will itself, being for its explanation or alteration, to add something to, or take something from, the former disposition, and which may also be either written or verbal, under the same restrictions as regard wills.

If two wills are found, and it does not appear which was the former or latter, both will be void; but if two codicils are found, and it cannot be ascertained which was the first, but the same thing is devised to two persons, both ought to divide; but where either wills or codicils have dates, the latter is considered as valid, and revokes the former. See ADMINISTRATOR, EXECUTOR, and LEGACY.

WILL WITH A WISP, or *Jack with a lanthorn.* See METEOR.

WILLICHIA, a genus of plants of the class and order triandria monogynia. The calyx is four-cleft; corolla ditto; capsule two-celled, many-seeded. There is one species, an annual of Mexico.

WILLUGHBEIA, a genus of plants of the pentandria monogynia class and order. It is contorted; corolla salver-shaped; stigma headed; fruit one or two celled, berry or pumpkin. There are two species, trees of Guiana.

WIND, a sensible current in the atmosphere. The motions of the atmosphere are subject, in a certain degree, to the same laws as those of denser fluids. If we remove a portion of the water in a large reservoir, we see the surrounding water flow in to restore the equilibrium. If we impel, in any direction, a certain portion, an equal quantity moves in a contrary direction from the same cause. If a portion, being rarified by heat, or condensed by cold, ascends or descends, a counter-current in another part is the necessary and visible result. It is thus in the atmosphere. No wind can blow without a counter-current in an opposite direction; or arise without a previous destruction of the equilibrium, the general causes of which are, 1. The ascent of the air over certain tracts, heated by the sun. 2. Evaporation causing an actual increase in the volume of the atmosphere. 3. Rain, &c. causing an actual decrease in volume by the destruction of the vapour. Currents thus produced may be permanent and general, extending over a large portion of the globe; periodical as in the Indian ocean; or variable, and as it were occasional, or at least uncertain, as the winds in temperate climates.

General or permanent winds blow always nearly in the same direction. In the Atlantic and Pacific oceans, under the equator, the wind is almost always easterly; it blows, indeed, in this direction, on both sides of the equator to the latitude of 28°. More to the northward of the equator, the wind generally blows between the north and east; and the farther north we proceed, we find the wind to blow to a more northern direction; more to the southward of the equator it blows between the south and east; and the farther to the south, the more it comes in that direction.

Between the parallels of 28° and 40° south lat. in that tract which extends from 30° west to 100° east longitude from London, the wind is variable, but it most frequently blows from between the N. W. and S. W. so that the outward-bound East India ships generally run down their easting on the parallel of 36° south.

Navigators have given the appellation of trade-winds to these general winds.

Periodical winds. Those winds, which blow in a certain direction for a time, and at certain stated seasons change and blow for an equal space of time from the opposite point of the compass, are called monsoons. During the months of April, May, June, July, August, and September, the wind blows from southward over the whole length of the Indian ocean, viz. between the parallels of 28° N. and 28° S. lat. and between the eastern coast of Africa and the meridian which passes through the western part of Japan; but in the other months, October, November, December, January, February, and March, the winds in all the northern parts of the Indian ocean shift round, and blow directly contrary to the course they held in the former six months. For some days before and after the change, there are calms, variable winds, and tremendous storms, with thunder, &c.

Philosophers differ in their opinions respecting the cause of these periodical winds; but a more probable theory of the general trade-winds is, that they are occasioned by the heat of the sun in the regions about the equator, where the air is heated to a greater degree, and consequently rarefied more, than in the more northern parts of the globe. From this expansion of the air in these tropical regions, the denser air, in higher latitudes, rushes violently towards the equator from both sides of the globe. By this conflux of the denser air, without any other circumstances intervening, a direct northerly wind would be produced in the northern tropic, and a southern one in the other tropic; but as the earth's diurnal motion varies the direct influence of the sun over the surface of the earth, and as by that motion this influence is communicated from east to west, an easterly wind would be produced if this influence alone prevailed. On account of the co-operation of these two causes at the same time, the trade-winds blow naturally from the N. E. on the north, and from the S. E. on the south of the Line, throughout the whole year; but as the sun approaches nearer the tropic of Cancer in our summer season, the point towards which these winds are directed will not be invariably the same, but they will incline more towards the north in that season, and more towards the south in our winter.

The land and sea breezes in the tropical climates may be considered as partial interruptions of the general trade-winds; and the cause of these it is not very difficult to explain. From water being a better conductor of heat than earth, the water is always of a more even temperature. During the day, therefore, the land becomes considerably heated, the air rarefied, and consequently in the afternoon a breeze sets in from the sea, which is less heated at that time than the land. On the other hand, during the night the earth loses its surplus heat, while the sea continues more even in its temperature. Towards morning, therefore, a breeze regularly proceeds from the land towards the ocean, where the air is warmer, and consequently more rarefied, than on shore.

The cause of the monsoons is not so well understood as that of the general trade-winds, but what has been just remarked, suggests, at least, a probable theory on the subject. It is well known, that at the equator the changes of heat and cold are occasioned by the diurnal motion of the earth, and that the difference between the heat of the day and the night is almost all that is perceived in those tropical regions; whereas in the polar regions the great vicissitudes of heat and cold are occasioned by the annual motion of the globe, which produces the sensible changes of winter and summer; consequently, if the heat of the sun was the only cause of the variation of the winds, the changes, if any, that would be produced by those means in equatorial regions, ought to be diurnal only, but the changes about the pole should be experienced only once in six months. As the effects arising from the heat of the sun upon the air must be greater at the equator than at the poles, the changes of the wind arising from the expansion of the air by the sun's rays must be more steady in equatorial than in polar regions. The incontrovertible evidence of navigators proves this truth, that winds are more variable towards the poles, and more constant towards the equator. But in summer, the continual heat, even in high latitudes, comes to be sensibly felt, and produces changes on the wind, which are distinctly perceptible. In our own cold region, the effects of the sun on the wind are felt during the summer months; for while the weather in that season of the year is fine, the wind generally becomes stronger as the time of the day advances, and dies away towards the evening, and assumes that pleasing serenity so delightful to our feelings. Such are the diurnal changes of the wind in northern climates. The annual revolution of the sun produces still more sensible effects. The prevalence of the western winds during summer we may attribute to this cause, which is still more perceptible in France and Spain; because the continent of land to the eastward, being heated more than the waters of the Atlantic ocean, the air is drawn, during that season, towards the east, and consequently produces a western wind.

But these effects are much more perceptible in countries near the tropics than with us. For when the sun approaches the tropic of Cancer, the soil of Persia, Bengal, China, and the adjoining countries, becomes so much more heated than the sea to the southward of those countries, that the current of the general trade-wind is interrupted, so as to blow, at that season, from the south to the north, contrary to what it would do if no land was there. But as the high mountains of Africa, during all the year, are extremely cold, the low countries of India, to the eastward of it, become hotter than Africa in summer, and the air is naturally drawn thence to the eastward. From the same cause it follows, that the trade-wind in the Indian ocean, from April till October, blows in a north-east direction, contrary to that of the general trade-wind in open seas in the same latitude; but when the sun retires towards the tropic of Capricorn, these northern parts become cooler, and the general trade-wind assumes its natural direction.

Having given the most obvious causes of the periodical monsoons in the Indian seas, it is necessary to observe, that no monsoon takes place to the southward of the equator, except in that part of the ocean adjoining to New Holland. There the same causes concur to produce a monsoon as in the northern tropic, and similar appearances take place. From October till April the monsoon sets in from the N. W. to S. E. opposite to the general course of the trade-wind on the other side of the Line; and here also the general trade-wind resumes its usual course during the other months, which constitute the winter season in these regions. It may not be improper to conclude this account of the tropical winds, by enumerating some of the principal inflections of the monsoons.

Between the months of April and October the winds blow constantly from W. S W. in all that part of the Indian ocean which lies between Madagascar and cape Comorin, and in the contrary direction from October till April, with some small variation in different places; but in the bay of Bengal these winds are neither so strong nor so constant as in the Indian ocean. It must also be remarked, that the S. W. winds in those seas are more southerly on the African side, and more westerly on the side of India; but these variations are not so great as to be repugnant to the general theory. The cause of this variation is, as was before intimated, that the mountainous lands of Africa are colder than the flatter regions of Arabia and India; consequently the wind naturally blows from these cold mountains, in the summer season, towards the warmer lands of Asia, which occasions those inflections of the wind to the eastward during the summer months. The peninsula of India, lying so much farther to the south than the kingdoms of Arabia and Persia, adds greatly to this effect; because the wind naturally draws towards them, and produces that easterly variation of the monsoon which takes place in this part of the ocean, while the sandy deserts of Arabia draw the winds more directly northward, near the African coast. A similar chain of reasoning will serve to explain any other inflections or variations that may occur in the perusal of books of travels, &c.

Winds, *variable.* In the temperate zones the direction of the winds is by no means so regular as between the tropics. Even in the same degree of latitude we find them often blowing in different directions at the same time; while their changes are frequently so sudden and so capricious, that to account for them has hitherto been found impossible. When winds are violent, and continue long, they generally extend over a large tract of country; and this is more certainly the case when they blow from the north or east than from any other points. By the multiplication and comparison of meteorological tables, some regular connection between the changes of the atmosphere in different places may in time be observed, which will at last lead to a satisfactory theory of the winds. It is from such tables chiefly, that the following facts have been collected:

In Virginia, the prevailing winds are between the south-west, west, north, and north-west; the most frequent is the south-west, which blows more constantly in June, July, and August, than at any other season. The north-west winds blow most constantly in November, January, and February. At Ipswich, in New England, the prevailing winds are also between the south-west, west, north, and north-east; the most frequent is the north-west. But at Cambridge, in the same province, the most frequent wind is the south-east. The predominant winds at New York are the north and west; and in Nova Scotia north-west winds blow for three-fourths of the year. The same wind blows most frequently at Montreal in Canada; but at Quebec the wind generally follows the direction of the river St. Lawrence, blowing either from the north-east or south-west. At Hudson's-bay westerly winds blow for three-fourths of the year; the north-west wind occasions the greatest cold, but the north and north-east are the vehicles of snow.

It appears from these facts, that westerly winds are most frequent over the whole eastern coast of North America; that in the southern provinces, south-west winds predominate; and that the north-west become gradually more frequent as we approach the frigid zone.

In Egypt, during part of May, and during June, July, August, and September, the wind blows almost constantly from the north, varying sometimes in June to the west, and in July to the west and the east; during part of September, and in October and November, the winds are variable, but blow more regularly from the east than any other quarter; in December, January, and February, they blow from the north, north-west, and west; towards the end of February they change to the south, in which quarter they continue till near the end of March; during the last days in March and in April, they blow from the south-east, south, and south-west, and at last from the east; and in this direction they continue during a part of May.

In the Mediterranean the wind blows nearly three-fourths of the year from the north; about the equinoxes there is always an easterly wind in that sea, which is generally more constant in spring than in autumn. These observations do not apply to the gut of Gibraltar, where there are seldom any winds except the east and the west. At Bastia, in the island of Corsica, the prevailing wind is the south-west.

In Syria the north wind blows from the autumnal equinox to November; during December, January, and February, the winds blow from the west and south-west; in March they blow from the south, in May from the east, and in June from the north. From this month to the autumnal equinox, the wind changes gradually as the sun approaches the equator; first to the east, then to the south, and lastly to the west. At Bagdad, the most frequent winds are the south-west and north-west; at Pekin, the north and the south; at Kamtschatka, on the north-east coast of Asia, the prevailing winds blow from the west.

In Italy, the prevailing winds differ considerably according to the situation of the places where the observations have been made: at Rome and Padua, they are northerly, at Milan easterly. All that we have been able to learn concerning Spain and Portugal is, that on the west coast of these countries, the west is by far the most common wind, particularly in summer; and that at Madrid the wind is north-east for the greatest part of the summer, blowing almost constantly from the Pyrenean mountains. At Berne in Switzerland, the prevailing winds are the north and west; at St. Gothard, the north-east; at Lausanne, the north-west and south-west.

Father Cotte has given us the result of observations made at 86 different places of France; from which it appears, that along the whole south coast of that kingdom the wind blows most frequently from the north, north-west and north-east; on the west coast, from the west, south-west, and north-west; and on the north coast from the south-west. That in the interior parts of France, the south-west wind blows most frequently in 18 places; the west wind in 14; the north in 13; the south in 6; the north-east in 4; the south-east in 2; the east and north-west each of them one. On the west coast of the Netherlands, as far as Rotterdam, the prevailing winds are probably the south-west, at least this is the case at Dunkirk and Rotterdam. It is probable also, that along the rest of this coast, from the Hague to Hamburgh, the prevailing winds are the north-west, at least these winds are most frequent at the Hague and at Franeker. The prevailing wind at Delft is the south-east; and at Breda, the north and the east.

In Germany, the east wind is most frequent at Gottingen, Munich, Weissemburgh, Dusseldorf, Saganum, Erford, and at Buda in

Hungary; the south-east at Prague and Wirtzburg; the north-east at Ratisbon; and the west at Manheim and Berlin.

From an average of ten years of the register kept by order of the Royal Society, it appears that at London the winds blow in the following order:

Winds.	Days.	Winds.	Days.
South-west	112	South-east	32
North-east	58	East	26
North-west	50	South	18
West	53	North	16

It appears, from the same register, that the south-west wind blows at an average more frequently than any other wind during every month of the year, and that it blows longest in July and August; that the north-east blows most constantly during January, March, April, May, and June, and most seldom during February, July, September, and December; and that the north-west wind blows oftener from November to March, and more seldom during September and October than any other months. The south-west winds are also most frequent at Bristol, and next to them are the north-east.

The following table of the winds at Lancaster has been drawn up from a register kept for seven years at that place:

Winds.	Days.	Winds.	Days.
South-west	92	South-east	35
North-east	67	North	30
South	51	North-west	26
West	41	East	17

The following table is an abstract of nine years observations made at Dumfries by Mr. Copland:

Winds.	Days.	Winds.	Days.
South	82½	North	36½
West	69	North-west	25½
East	68	South-east	28½
South-west	50½	North-east	14½

The following table is an abstract of seven years observations made by Dr. Meek at Cambuslang, near Glasgow:

Winds.	Days.	Winds.	Days.
South-west	174	North-east	104
North-west	40	South-east	47

It appears, from the register from which this table was extracted, that the north-east wind blows much more frequently in April, May, and June, and the south-west in July, August, and September, than at any other period. The south-west is by far the most frequent wind all over Scotland, especially on the west coast. At Saltcoats, in Ayrshire, for instance, it blows three-fourths of the year; and along the whole coast of Murray, on the north-east side of Scotland, it blows for two-thirds of the year. East winds are common over all Great Britain during April and May; but their influence is felt most severely on the eastern coast.

The following table exhibits a view of the number of days during which the westerly and easterly winds blow in a year at different parts of the island. Under the term westerly are included the north-west, west, south-west, and south; the term easterly is taken in the same latitude.

Years of Observ.	Places.	Wind. Westerly.	Easterly
10	London - -	233	132
7	Lancaster - -	216	149
51	Liverpool - -	190	175
9	Dumfries - -	227.5	137.5
10	Branxholm, 54 miles south-west of Berwick - - -	232	133
7	Cambuslang - -	214	151
8	Hawkhill, near Edinburgh - - -	229.5	135.5
	Mean	220.3	144.7

In Ireland, the south-west and west, are the grand trade-winds; blowing most in summer, autumn, and winter, and least in spring. The north-east blows most in spring, and nearly double to what it does in autumn and winter. The south-east and north-west are nearly equal, and are most frequent after the south-west and west.

At Copenhagen the prevailing winds are the east and south-east; at Stockholm, the west and north. In Russia, from an average of a register of 16 years, the winds blow from November to April in the following order:

	W.	N.W.	E.	S.W.	S.	N.E.	N.	S.E.
Days	45	26	23	22	20	19	14	12

And during the other six months,

	W.	N.W.	E.	S.W.	S.	N.E.	N.	S.E.
Days	27	27	19	24	22	15	32	18

The west wind blows during the whole year 72 days; the north-west 58; the south-west and north 46 days each. During summer it is calm for 41 days, and during winter for 21. In Norway, the most frequent winds are the south, the south-west, and south-east. The wind at Bergen is seldom directly west, but generally south-west, or south-east; a north-west, and especially a north-east wind, are but little known there.

From the whole of these facts, it appears that the most frequent winds on the south coasts of Europe are the north, the north-east, and north-west; and on the western coast, the south-west: that in the interior parts which lie most contiguous to the Atlantic ocean, south-west winds are also most frequent; but that easterly winds prevail in Germany. Westerly winds are also most frequent on the north-east coast of Asia.

It is probable that the winds are more constant in the south temperate zone, which is in a great measure covered with water, than in the north temperate zone, where their direction must be frequently interrupted and altered by mountains and other causes.

M. De la Caille, who was sent thither by the French king to make astronomical observations, informs us, that at the Cape of Good Hope the main winds are the south-east and north-west; that other winds seldom last longer than a few years; and that the east and north-east winds blow very seldom. The south-east wind blows in most months of the year, but chiefly from October to April; the north-west prevails during the other six months, bringing along with it rain, and tempests, and hurricanes. Between the Cape of Good Hope and New Holland, the winds are commonly westerly, and blow in the following order: north-west, south-west, west, north.

In the Great South Sea, from latitude 30° to 40° south, the south-east trade-wind blows most frequently, especially when the sun approaches the tropic of Capricorn; the wind next to it in frequency is the north-west, and next to that is the south-west. From south latitude 40° to 50°, the prevailing wind is the north-west, and next the south-west. From 50° to 60°, the most frequent wind is also the north-west, and next to it is the west.

Thus it appears that the trade-winds sometimes extend farther into the south temperate zone than their usual limits, particularly during summer; that beyond their influence the winds are commonly westerly, and that they blow in the following order: north-west, south-west, west.

Such is the present state of the history of the direction of the winds. In the torrid zone they blow constantly from the north-east on the north side of the equator, and from the south-east on the south side of it. In they north temperate zone they blow most frequently from the south-west; in the south temperate zone from the north-west, changing, however, frequently to all points of the compass; and in the north temperate zone blowing, particularly during spring, from the north-east.

As to the velocity of the wind, its variations are almost infinite; from the gentlest breeze, to the hurricane which tears up trees and blows down houses. It has been remarked, that our most violent winds take place when neither the heat nor the cold is greatest; that violent winds generally extend over a great tract of country, and that they are accompanied by sudden and great falls in the mercury of the barometer. The reason appears to be, that violent winds succeed the precipitation in rain of a large quantity of vapour, which previously constituted a part of the bulk of the atmosphere; and this precipitation cannot take place when the general temperature approaches to either extreme. The wind is sometimes very violent at a distance from the earth, while it is quite calm at its surface. On one occasion Lunardi went at the rate of 70 miles an hour in his balloon, though it was quite calm at Edinburgh when he ascended, and continued so during his whole voyage. The same thing happened lately to Garnerin and his companion in their aerostatic voyage to Colchester. This again may be illustrated by the motions of dense fluids, which are always impeded in the parts contiguous to the sides and bottom of the vessels; and the same thing happens in tide-rivers, where the boatman, when he wishes to proceed with the tide, commits himself to the middle of the stream: but when he has to strive against it, he keeps close to the shore. It is, therefore, not the upper parts of the atmosphere which are accelerated, but the lower are retarded by friction against the surface of the earth.

The following table, drawn up by Mr. Smeaton, will give the reader a pretty precise idea of the velocity of the wind in different circumstances:

Miles per Hour.	Feet per Second.	Perpendicular Force on one square Foot, in Avoirdupois Pounds and Parts.	
1	1.47	.005	Hardly perceptible
2.	2.93	.020	Just perceptibe
3	4.4	.044	
4	5.87	.079	Gently pleasant
5	7.33	.123	
10	14.67	.492	Pleasant, brisk
15	22.	1.107	
20	29.34	1.968	Very brisk
25	36.67	3.075	
30	44.01	4.429	High wind
35	51.34	6.027	
40	58.68	7.873	Very high wind
45	66.01	9.963	
50	73.35	12.300	Storm or tempest
60	88.02	17.715	Great storm
80	117.36	31.490	Hurricane
100	146.7	49.200	Hurricane, that tears up trees, and carries buildings before it.

WINDMILL, a kind of mill, the internal parts of which are much the same with those of a water-mill; from which, however, it differs in being moved by the impulse of the wind upon its vanes, or sails, which are to be considered as a wheel on the axle.

There are various kinds of windmills. We shall content ourselves with describing the horizontal windmill, the construction of which is not so generally known as that of the others.

Plate Windmill, represents an horizontal windmill erected about 50 years ago at a distillery near Battersea, for grinding malt and corn. AA (fig. 1) is the main shaft, which turns on a gudgeon working in a socket supported by solid masonry: this shaft has several wheels, as BB, attached to its upper part, as shewn in fig. 2, for carrying a great number of float-boards DD, similar to a water-wheel, except being a little conical. This wheel is inclosed in a frame EE, composed of several circular rings, connected by upright timbers, and strengthened by transverse braces, and which has timbers across the top to support the upper gudgeon of the shaft AA. Within the frame EE, are a great number of boards extending from top to bottom, as shewn at FF: the boards turn on a centre at the edge nearest the wheel, so that they can be set open, as in fig. 2, or be shut up so as to touch one another, and to allow no air to pass between them.

When the boards FF are set, as in fig. 2, it will be evident, from inspecting the figure, that let the wind blow in any direction, it will always enter the building on one side, the other being in such a position that the wind cannot enter, and striking on the floats of the wheel will turn it round. The quantity of wind which strikes the wheel can be regulated by closing or opening the boards, FF, all at once, which is done by a contrivance, shewn in fig. 3. HH represents a plan of a part of the circular sill at the bottom of the frame EE, (figs. 1 and 2); FF are the wind-boards, which move on a centre at the edge *f*; the boards have levers, GG, nailed to their lower ends, by which they can be turned about on the centre; II are rods, joined to the levers GG, the other ends of which are jointed to a circular ring, of which KK is a segment: this ring rests upon rollers fixed in the floor beneath the sails.

When this ring is turned round one way, the rods II push the ends of the levers GG, and close up the boards; on the contrary, when it is turned the other way, it opens them.

The ring K has at one part of its under side a short cast iron segment with cogs, which work in a pinion, moving on centres fixed to the floor. The axis of this pinion goes through the mill and into the open air, and is connected by ropes with a handle below the ground-floor of the mill.

When the miller turns this handle, it also turns the ring K (fig. 3), and, as before described, opens or closes the boards FF, and regulates the mill's velocity.

The main shaft, AA, has a large cog-wheel, O, fixed upon it, which turns two trundles on the shafts, LM, on which the wheels NN are also fixed: each of these wheels turns three pinions (only one of which is represented) on the axis of the mill-stones, which are arranged round the wheels NN, at proper intervals, like those described under the article FLOUR-MILL. The shaft L has a beveled wheel at its upper end, which turns another, *m*, on the shaft *n*; which has riggers, as P, fixed on it, and by means of straps turns the bolting-mills; for a description of which see FLOUR-MILL.

With regard to the common windmills, we must observe that a patent has lately been taken out by Mr. Sutton, for a peculiar construction of the sails. For a full account of these, we can with pleasure refer to a work entitled "A Sketch of the Properties and Advantages of Sutton's Patent Gravitated Sails for Windmills," by W. S. Hefleden.

WIND-SAILS, in a ship, are made of the common sail-cloth, and are usually between 25 and 30 feet long, according to the size of the ship, and are of the form of a cone ending obtusely: when they are made use of, they are hoisted by ropes to about two-thirds or more of their height, with their basis distended circularly by hoops, and their apex hanging downwards in the hatchways of the ship; above each of these, one of the common sails is so disposed, that the greatest part of the air rushing against it is directed into the wind-sail, and conveyed, as through a funnel, into the upper parts of the body of the ship.

WIND-TACKLE-BLOCKS, in a ship, are the main double blocks, which, being made fast to the end of a small cable, serve for hoisting goods into the ship, &c.

To WIND, or WEND, *a ship*, signifies to bring her head about. How winds or wends a ship? is a question asked by mariners concerning a ship under sail; signifying as much as, upon what point of the compass does she lie with her head?

WIND-WARD, in the sea language, denotes any thing towards that point from which the wind blows in respect of a ship: thus windward tide is the tide which runs against the wind.

Large WIND. In the sea language, to sail with a large wind, is the same as with a fair wind.

WINDAGE *of a gun, mortar, or howitzer*. The difference between the diameter of the bore, and the diameter of the shot or shell. In England, the diameter of the shot is supposed to be divided into 20 equal parts, and the diameter of the bore into 21 of those parts. The French divide the shot into 26, and the bore into 27. The Prussians divide the shot into 24, and the bore into 25. The Dutch nearly the same as the English. The general windage of shells in England is a quarter of an inch, let them be large or small, which is contrary to all reason. It is evident, that the less windage a shot or shell has, the farther and truer it will go; and having less room to bounce from side to side, the gun will not be spoiled so soon.

It is true that some artillery-officers say, that the windage of a gun should be equal to the thickness of the ladle; because, when it has been loaded for a while, the shot will not come out without being loosened thereby, in order to unload it; and when this cannot be done, it must be fired away, and so lost; but the most advantageous windage would be in dividing the shot in 24 equal parts, and the bore into 25, on account of the convenient scale it affords, not only to construct guns by, but also their carriages. Hence, agreeable to this plan, the windage of a 9-pounder will be .166 of an inch, consequently a sufficient thickness for a ladle; and those of a higher calibre become still thicker in proportion; but suppose this thickness is not enough, the loss of a shot is a mere trifle, in respect to the advantage otherwise gained.

WINDING STAIRS. See STAIRS.

WINDLASS, or WINDLACE, a machine used to raise large weights, as guns, stones, anchors, &c. See MECHANICS.

WINDLASS, in a ship, is an instrument, in small ships placed upon the deck, just abaft the foremast. It is made of a piece of timber six or eight feet square, in form of an axle-tree, whose length is placed horizontally upon two pieces of wood at the ends, and upon which it is turned about by the help of handspikes put into holes made for that purpose. This instrument serves for weighing anchors, or hoisting of any weight in or out of the ship, and will purchase much more than any capstan, and that without any danger to those who heave; for if in heaving the windlass about, any of the handspikes should happen to break, the windlass would pall of itself.

WINDOW. See ARCHITECTURE.

WINE. It is known that no substances, except such as contain the saccharine principle, are susceptible of the vinous fermentation; and that in order to be susceptible of it, these saccharine substances must always contain a certain portion of extractive matter; for Lavoisier has proved, that sugar alone cannot ferment, he having always been obliged to add to it a quantity of yeast in order to make it undergo this change.

The principles of which yeast consists are oxygen, hydrogen, carbon, and azote. The process of fermentation decomposes them, and gives rise to new products, namely:

Water, carbonic acid, alcohol, acetous acid, saccharine residuum, and a residuum of the yeast.

The effects of the vinous fermentation consist, therefore, in separating the sugar, which is an oxide, into two parts; in oxygenating the one, at the expence of the other, to form carbonic acid; in disoxygenating the other in favour of the first, to form a combustible substance termed alcohol; so that was it possible to combine these two substances, the alcohol and the carbonic acid, one might reproduce sugar. It is necessary to remark, that the hydrogen and carbon do not exist in the state of oil in alcohol, being combined with a portion of oxygen, which renders them miscible with water. These three principles, therefore, the oxygen, the hydrogen, and the carbon, are here in a kind of equilibrium; and, in fact, by causing them to pass through a red-hot tube of glass or porcelain, we may re-combine them two and two together, and the product will be water, hydrogen, carbonic acid, and carbon.

The analysis of wine commences in the cask, after which it successively deposits tartar, lees, and its colouring principle, till at length hardly any thing remains besides alcohol and a small quantity of extractive matter, dissolved in a proportion of water more or less abundant. But this accurate analysis, which exhibits to us the principles of wines in their separate states, throws very little light upon their real nature, a deficiency which we shall endeavour to supply by a more rigorous method of investigation.

We shall distinguish in all wines an acid, alcohol, tartar, an extractive matter, aroma, and a colouring principle; the whole being diluted or dissolved in a smaller or larger proportion of water.

1. *The acid.* An acid exists in all wines; and we have never met with any in which we could not discover some traces of its presence. The sweetest, as well as the most watery wines, impart a red tinge to blue paper that is kept for some time immersed in them; but all wines are not acid in the same degree. Of some wines, a natural acidity is the principal characteristic; those produced from grapes not perfectly ripe, or that grow in moist climates, are of this kind; whilst such as are the product of the fermentation of grapes that have attained complete maturity and sweetness, contain but a very small quantity of acid. The proportion of acid appears, therefore, to be in the inverse ratio of the saccharine principle, and consequently of the alcohol, which is produced by the decomposition of the sugar.

This acid exists in great abundance in verjuice; it is also found in must, though in less quantity. All fermented liquors, such as cyder, perry, beer, and fermented farinaceous substances, contain this acid in like manner. It is even found in melasses. Indeed, it is only for the purpose of completely saturating it, that lime, ashes, and other earthy or alkaline bases, are used in refining sugar; otherwise the presence of the acid would impede the crystallization of this salt.

If we concentrate wine by distillation, the extract which remains is in general of a sour pungent taste. Water, or even alcohol, poured upon this extract, will be sufficient to dissolve and raise the acid. This acid has a slightly empyreumatic smell, leaves a bitterish taste in the mouth, &c.

This acid, well filtrated and left to stand in a flask, deposits a considerable quantity of extractive matter; it afterwards becomes covered with mould, and seems to approach to the nature of the acetous acid; by distillation it may be purified of a great quantity of the extractive matter, after which it becomes less liable to be decomposed by the putrefactive fermentation.

This acid precipitates the carbonic acid in its combinations; it dissolves most of the metallic oxides with facility; forms insoluble salts with lead, silver, and mercury; and separates the metals from all their solutions by acids.

This acid forms also an insoluble salt with lime. When we mix a large quantity of lime-water with wine, the acid is precipitated from it, and carries with it the whole of the colouring principle.

This acid, therefore, is of the nature of the malic acid; it is always mixed with a small proportion of nitric acid; for, if it is digested upon the oxide of lead, besides the insoluble precipitate that is formed, a citrate is always produced which can be demonstrated by the known methods.

This malic acid disappears when the wine is converted into vinegar; it no more exists in well-prepared vinegar than it does in the acetous acid. This transformation of the malic acid into acetous acid, affords a natural explanation why wine that has begun to sour cannot be employed in the preparation of the acetite of lead; in this case an insoluble precipitate is produced.

The existence, in different proportions, of the malic acid in wine, enables us to account for a phenomenon of the utmost importance, relative to the distillation of wines, and the properties of the vinous spirits which result from this process. Every one knows, not only that all wines do not yield the same proportion of spirit, but likewise that the distilled spirits produced from different kinds of wine differ very widely from each other in their quantities. It is also well known that beer, cyder, perry, and fermented farinaceous substances, yield but a small quantity of spirit, and that always of a bad quality. Careful and repeated distillations may indeed correct these faults to a certain degree, but they can never take them away altogether. These constant results, from a long course of experience, have been attributed to the superabundance of the extractive matter contained in these weak spirituous liquors; the combustion of a portion of this matter, by distillation, seemed to be the immediate consequence, and the acrid empyreumatic taste its natural effect. But, upon a more accurate investigation of this phenomenon, it is found that, besides the causes dependant upon the superabundance of the extractive principle, another ought to be attended to, namely, the presence of the malic acid in almost all these cases.

Those wines which contain the largest proportion of malic acid, afford the worst-conditioned spirit. It appears even that the quantity of alcohol is less in proportion as that of the acid is more considerable. If we separate this acid by means of lime-water, lime, chalk, or some fixed alkali, we can only draw off a very small quantity of alcohol by distillation; and, in every case, the spirit acquires a disagreeable fiery taste, which does not tend to meliorate its quality.

The difference of the spirits obtained by distillation from different wines, depends, therefore, principally upon the different proportions in which these wines contain malic acid; but no process has been hitherto discovered by which we can with certainty destroy the bad effects which the admixture of this acid with vinous spirits produces.

This acid, which we find in the grape at the period of its growth, and which does not disappear in wines till they have completely degenerated into vinegar, ought in preference to be denominated the vinous acid: however, for the sake of avoiding innovation, we shall retain the usual term of malic acid.

2. *Alcohol.* Alcohol forms the true characteristic of wine. It is the product of the decomposition of sugar; and its quantity is always proportionate to that of the sugar that has been decomposed.

Alcohol abounds more in some wines than it does in others; those of hot climates contain a large quantity of it, whilst those of cold climates contain scarcely any. Ripe and sweet grapes produce it in abundance; but the wines made of grapes that are unripe, watery, and sour, yield very little.

Some wines produced in the southern parts of our hemisphere, yield alcohol in the proportion of one-third of their quantity; whilst many of those manufactured in more northern latitudes contain not more than one-fifteenth.

It is the proportion of alcohol contained in them that renders wines more or less generous; and upon the same circumstance depends their disposition or resistance to the acetous fermentation. The less a wine contains of alcohol, the more easily it turns sour; the proportion of extractive matter contained in it being supposed the same in both cases.

The richer in spirit a wine is, the less it contains of malic acid; and this is the reason why the best wines, in general, furnish the best brandies; as they are then exempt from the presence of this acid, which gives them a disagreeable flavour.

It is by distillation that we extract from wines the whole of the alcohol they contain.

When wines are distilled, the operation is carried on till the liquor which passes over is no longer inflammable.

Wines furnish more or less brandy in proportion to their different degrees of spirituosity. A very generous wine furnishes about a third of its weight: the mean proportion of the brandy, furnished by the wines of the southern provinces of France, is about one-fourth of the whole; some even yield as much as one-third.

Old wines yield better brandy than new ones, but in less quantity, particularly when the decomposition of the saccharine principle has been completed before they are subjected to the process of distillation.

That which remains in the boiler, after the brandy has been extracted, is called vinasse; and is a confused mixture of tartar, the colouring principle, lees, &c. This residuum is generally thrown away as useless: nevertheless, after drying it in the air, or by means of a stove, a tolerably pure alkali may be extracted from it by combustion.

In some distilleries the vinasse is suffered to turn sour, in order afterwards to distil, and extract the small quantity of vinegar that has been formed in it.

Brandy is the more spirituous in proportion as it is mixed with a smaller proportion of water; and as it is of importance in commerce, that we should be able easily to ascertain the degrees of spirituosity, attention has long been paid to the means by which this may be performed.

The distiller judges of the spirituosity of brandy by the number, the magnitude, and the permanency, of the bubbles which form themselves upon agitating the liquor. With this view it is poured from one vessel into another, or suffered to fall from a certain height, or, which is the more general practice, it is inclosed in an oblong flask, so as to fill about two-thirds of the whole, and violently agitated, the mouth of the flask being kept tightly closed by the pressure of the thumb. This last apparatus is called the sound.

The test by combustion, in the manner it is usually practised, is very faulty. The regulation of the year 1729 directs to put gunpowder into a boiler, and, after covering it with the liquid, to apply fire to it. The brandy is supposed to be of good quality if it sets fire to the powder, and bad in the contrary event. But the same quantity of liquor either does, or does not, set fire to gunpowder, according to the proportion in which it is employed: a small proportion always does it, and a large one never; for, in the latter case, the water contained in the liquid is sufficient to wet the powder, and prevent its taking fire.

Salt of tartar (carbonat of potass) is also employed as a test for brandy. This alkali is soluble in water, but not in alcohol; so that upon dissolving it in brandy, the alcohol swims at the top of the solution.

The defective nature of these processes has rendered it necessary to have recourse to means capable of determining the spirituosity of a liquor by ascertaining its specific gravity.

A drop of oil poured upon alcohol fixes itself upon the surface, or falls to the bottom, according to the degree of spirituosity which the liquor possesses. This method has been adopted and proposed by the Spanish government in the year 1770; but it is subject to inaccuracy, as the effect depends upon the height from which it falls, the weight of the oil, the size of the drop, the temperature of the atmosphere, the dimensions of the vessel, &c.

In the year 1772, this important subject was resumed by two able philosophers, namely, Borie and Proujet de Cette, who introduced in Languedoc, an hydrometer, to which they adapted a thermometer, the different degrees of which constantly indicate the corrections requisite to be made in the graduation of the hydrometer, on account of the very variable temperature of the atmosphere.

By the aid of this hydrometer, one may not only ascertain the degree of spirituosity, but also bring the brandy to any degree that is thought proper. For this purpose different weights are used, the heaviest of which is marked Holland-proof, and the highest 3—7; so that if we see, at the lower extremity of the stalk of the aräometer, Holland-proof, and plunge the instrument into a liquor 3—7, it sinks much too deep; but we may raise it again to the level of Holland-proof, by adding four-sevenths of water.

If, on the contrary, we have the weight 3—7, and plunge the aräometer into a liquor Holland-proof, it will rise in the liquor above this last term, to which it may easily be reduced by adding alcohol of a higher degree of spirituosity.

When brandies are to be distilled for the purpose of extracting their alcohol, the compound bath is usually employed. The heat is then more gentle and equal, and the product of the distillation of a better quality. This is what is called spirit of wine in commerce.

3. *The tartar*. Tartar exists in verjuice, as also in must; it contributes to facilitate the formation of alcohol, as we have already observed, according to the experiments of Bouillon. When left at rest in casks, it deposits itself upon the sides, forming a crust, more or less thick, with crystals of irregular forms. Some time before the vintage, when the casks are to be got ready for receiving the new wine, they are staved, and the tartar detached from them, in order to be employed in the different uses of commerce.

Tartar is not furnished in equal quantity by all wines; the red wines yield a larger proportion of it than the white: those of the deepest colour and thickest consistence generally yield the most.

Its colour likewise varies very much; and it is distinguished into white and red tartar, according to the colour of the wines from which it has been deposited.

This salt has little solubility in cold water, but considerably more in boiling water. It scarcely dissolves at all in the mouth, and it resists the pressure of the teeth.

It is deprived of its colouring principle by a simple process, and it is then termed cream of tartar. For this purpose it is dissolved in boiling water, and as soon as the solutiou is saturated, it is put into earthen pans to cool. In cooling, it deposits a layer of crystals, which are already very nearly deprived of their colour. These crystals are again dissolved in boiling water, and the solution mixed, in the proportion of four or five parts to a hundred, with a sandy argillaceous earth, which is dug at Murveil, near Montpellier. This mixture is evaporated till a pellicle forms upon it,; in cooling it deposits white crystals, which, after being exposed for some days to the air, upon canvas, acquire that whiteness by which cream of tartar is distinguished. The original water is preserved in order to be employed in new solutions.

Tartar is purified also by calcination. By this operation its acid is decomposed and destroyed, so that nothing remains besides the alkali and the carbon. The alkali is dissolved in water; and by filtrating and evaporating the solution, we obtain the salt well known in pharmacy by the name of salt of tartar, or carbonat of potass.

Tartar furnishes not more than about a fourth part of its weight of alkali.

4. *The extractive principle*. The extractive principle abounds in must, where it appears to be dissolved by the aid of the sugar: but when the saccharine principle is decomposed by means of fermentation, the quantity of extractive matter sensibly diminishes; a part of it deposits itself in a fibrous form; and this deposit, which principally constitutes the lees, is the more considerable in proportion as the fermentation is more gentle, and the alcohol more abundant. This deposit is always mixed with a considerable quantity of tartar.

There always exists in wine a proportion of extractive matter in a state of dissolution, which may be separated from it by means of evaporation. It abounds more in new wines than in old ones; and the older the wine grows, the more completely is it freed from the extractive principle.

The lees, after being well pressed, are dried in the sand, or in stoves, and then burnt, in order to extract that species of alkali known in commerce by the name of pearl-ashes. The residuum, after the combustion, is a porous mass, of a greenish-grey colour, and forms about a thirtieth part of the whole quantity of lees that have been burnt.

5. *The aroma*. All natural wines have an odour more or less agreeable to the smell. Some of them owe their reputation in a great measure to the perfume which they exhale. This is the case with Burgundy. This perfume is lost by too violent a fermentation, and becomes stronger by age. It seldom exists in very spirituous wines, either because it is concealed by the strong smell of the alcohol, or because it has been destroyed or dissipated by the violent fermentation that was requisite to develope the spirit.

This aroma does not appear to be capable of being extracted and communicated at pleasure to other substances. Even heat seems to destroy it; for, excepting the first liquid that passes over in distillation, which still retains something of the odour peculiar to the wine, the brandy which follows after has only those properties that essentially belong to it.

6. *The colouring principle*. The colouring principle of wine belongs to the skin of the grape; for when the must is suffered to ferment without it, the wine is white. This colouring principle does not dissolve till the alcohol is developed; it is only then that the wine acquires its colour, which is deeper in proportion to the violence of the fermentation.

A portion of the colouring principle deposits itself in the cask, together with the tartar and the lees; and, as the wine grows old, it is not unfrequent to see it entirely lose its colour: the colouring principle then deposits itself in pellicles on the sides or bottom of the cask, and is seen floating in the liquid in the form of films, which injure its transparency.

If we expose bottles filled with wine to the rays of the sun, a few days are sufficient to precipitate the colouring principle in large pellicles; the wine losing neither its perfume nor its strength.

By adding a large quantity of lime-water to wines, we precipitate their colouring principle. In this case the lime combines with the malic acid, and forms a salt which appears in light flakes in the liquid. These flakes gradually sink to the bottom, carrying with them the whole of the colouring principle. The deposit is black or white, according to the colour of the wine on which we operate. It frequently happens, that a wine is still susceptible of a new precipitation, although it had been completely discoloured by the first deposit, which proves that the colouring principle has a very strong affinity with the malate of lime. This coloured precipitate is not soluble either in cold or in hot water. Alcohol has scarcely any effect upon it, excepting that it acquires a slight brownish tinge. The nitric acid dissolves the colouring principle of this precipitate.

When wine is reduced to the state of extract, alcohol poured upon it acquires a deep tinge, in the same manner as water does, though not in an equal degree. But, besides the colouring principle which then dissolves itself, there is also a saccharine extractive principle present, which facilitates the solution.

The colouring principle, therefore, does not appear to be of a resinous nature; it exhibits all the characters that belong to a very numerous class of vegetable products, which approach to the nature of the lees of wine, though without possessing all its properties. The greater number of colouring principles are of this kind: they are soluble by the acid of extractive matter, and, upon disengaging them from this agent, they fix themselves in a solid form.

Wine-spirit, a term used by our distillers, and which may seem to mean the same thing with the phrase of spirit of wine; but they are taken in very different senses in the trade.

Spirit of wine is tbe name given to the common malt spirit, when reduced to an alcohol, or totally inflammable state; but the phrase wine-spirit is used to express a very clean and fine spirit, of the ordinary proof strength, and made in England from wines of foreign growth.

The way of producing it is by simple distillation, and it is never rectified any higher than common bubble-proof. The several wines of different natures yield very different proportions of spirit; but, in general, the strongest yield one-fourth, the weakest in spirits one-eighth part of proof-spirit; that is, they contain from a sixteenth to an eighth part of their quantity of pure alcohol.

WINNOWING-MACHINES. Machines of this sort are in pretty general use, where thrashing-mills, to which they may be attached, are not erected: they are made on different principles according to particular circumstances. Those contrived by Mr. Cor, of Leicester, on Mr. Winlow's plan, are good implements, and will dress grain with much dispatch. And there are others which are employed in the northern districts, which are made by Rodgers, that are also upon good and convenient principles; as well as many more in different places which have great merit in their construction, and do their work well and expeditiously. They are made of different prices, from three to five or six pounds, and will last many years when the materials of which they are formed are of a proper kind.

WINTERA, a genus of plants of the class polyandria, and order pentagynia; and in the natural system arranged under the 12th order, holoraceæ. The calyx is three-lobed; there are six or twelve petals; there is no style; the fruit is a berry, which is club-shaped as well as the germen. There are three species, the aromatica, granadensis, and axillaris.

Wintera aromatica, is one of the largest forest-trees upon Terra del Fuego: it often rises to the height of 50 feet. Its outward bark is on the trunk grey and very little wrinkled, on the branches quite smooth and green. The branches do not spread horizontally, but are bent upwards, and form an elegant head of an oval shape. The leaves come out without order, of an oval elliptic shape, quite entire, obtuse, flat, smooth, shining, of a thick leathery substance, evergreen, on the upper side of a lively deep-green colour, and of a pale bluish colour underneath, without any nerves, and their veins scarcely visible; they are somewhat narrower near the footstalks, and there their margins are bent downwards. In general, the leaves are from three to four inches long, and between one and two broad; they have very short footstalks, seldom half an inch long, which are smooth, concave on the upper side, and convex underneath. From the scars of the old footstalks the branches are often tuberculated.

WIRE, a piece of metal drawn through the hole of an iron into a thread of a fineness answerable to the hole it passed through.

Wires are frequently drawn so fine as to be wrought along with other threads of silk, wool, flax, &c.

The metals most commonly drawn into wire, are gold, silver, copper, and iron.

Gold wire is made of cylindrical ingots of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller; till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes one of the distinguishing characters of gold, is no where more conspicuous than in this gilt wire. A cylinder of 48 ounces of silver, covered with a coat of gold, only weighing one ounce, as Dr. Halley informs us, is usually drawn into a wire, two yards of which weigh no more than one grain: whence 98 yards of the wire weigh no more than 49 grains, and one single grain of gold covers the 98 yards; so that the ten-thousandth part of a grain is above one-eighth of an inch long.

Silver wire is the same with gold wire, except that the latter is gilt, or covered with gold, and the other is not.

There are also counterfeit gold and silver wires; the first made of a cylinder of copper, silvered over, and then covered with gold: and the second of a like cylinder of copper, silvered over, and drawn through the iron, after the same manner as gold and silver wire.

Brass wire is drawn after the same manner as the former. Of this there are divers sizes, suited to the different kinds of works. The finest is used for the strings of musical instruments, as harpsichords, &c.

The pin-makers likewise use vast quantities of brass wire, to make their pins of.

Iron wire is drawn of various sizes, from half an inch to one-tenth of an inch diameter, and even smaller.

The first iron that runs from the stone when melting, being the softest and toughest, is preserved to make wire of. Iron wire is made from bars of iron, called esleom-iron, which are first drawn out to a greater length, and to about the thickness of the little finger, at a furnace, with a hammer gently moved by water. These thinner pieces are bored round, and put into a furnace to anneal for 12 hours. A pretty strong fire is used for this operation. After this they are laid under water for three or four months, the longer the better; then they are delivered to the workmen, called rippers, who draw them into wire through two or three holes. After this they anneal them again for six hours, and water them a second time for about a week, and they are then delivered again to the rippers, who draw them into wire of the thickness of a large packthread. They are then annealed a third time, and then watered for a week longer, and delivered to the small wire-drawers, called overhouse-men.

In the mill where this work is performed, there are several barrels hooped with iron, which have two hooks on their upper sides, on each of which hang two links, which stand across, and are fastened to the two ends of the tongs which catch hold of the wire, and draw it through the hole. The axis on which the barrel moves does not run through the centre, but is placed on one side, which is that on which the hooks are placed; and underneath there is fastened to the barrel a spoke of wood, which they call a swingle, which is drawn back a good way by the cogs in the axis of the wheel, and draws back the barrel, which falls to again by its own weight. The tongs hanging on the hooks of the barrel, are by the workmen fastened to the end of the wire, and by the force of the wheel, the hooks being pulled back, draw the wire through the holes. The plate in which the holes are, is iron on the outside, and steel on the inside; and the wire is anointed with train-oil, to make it run the easier.

Wire *of Lapland*. The inhabitants of Lapland have a sort of shining slender substance in use among them on several occasions, which is much of the thickness and appearance of our silver wire, and is therefore called, by those who do not examine its structure or substance, Lapland wire. It is made of the sinews of the rein-deer, which being carefully separated in the eating, are, by the women, after soaking it in water, and beating, spun into a sort of thread, of admirable fineness and strength, when wrought to the smallest filaments; but when larger, is very strong, and fit for the purposes of strength and force. Their wire, as it is called, is made of the finest of these threads, covered with tin. The women do this business; and the way they take is to melt a piece of tin, and placing at the edge of it a horn with a hole through it, they draw these sinewy threads, covered with the tin, through the hole, which prevents their coming out too thick covered. This drawing is performed with their teeth; and there is a small piece of bone placed at the top of the hole, where the wire is made flat, so that we always find it rounded on all sides but one, where it is flat.

This wire they use in embroidering their clothes, as we do gold and silver; they often sell it to strangers, under the notion of its having certain magical virtues.

WITCHCRAFT. By 9 G. II. c. 5, no prosecution shall be commenced or carried on against any person for witchcraft, sorcery, enchantment, or conjuration, or for charging another with any such offence.

But if any person shall pretend to exercise or use any kind of witchcraft, sorcery, enchantment, or conjuration, or undertake to tell fortunes; or pretend from his skill or knowledge in any occult or crafty science, to discover where, and in what manner, any goods supposed to have been stolen or lost, may be found; he shall be imprisoned for a year, and once in every quarter of that year stand openly on the pillory for an hour; and further shall be bound to good behaviour as the court shall award.

WITENA-MOT, or Witena-gemot, among our Saxon ancestors, was a term which literally signified the assembly of the wise men, and was applied to the great council of the nation, of latter days called the parliament.

WITHERINGIA, a genus of plants of the class and order tetrandria monogynia. The corolla is sub-campanulate; calyx very small, four-toothed; perianthium two-celled. There is one species, a herb of South America.

WITZENIA, a genus of plants of the class and order triandria monogynia. The corolla is one-petalled; stigma emarginate; capsule superior. There is one species, a herb of the Cape.

WITHERNAM, in law, a writ that lies where a distress is driven out of the county, and the sheriff cannot make deliverance to the party distrained; in that case this writ is directed to the sheriff, commanding him to take as many of the beasts, or goods, of the party into his keeping, till he make deliverance of the first distress.

WITNESS, one who is sworn to give evidence in a cause.

If a man is subpœnaed as a witness upon a trial, he must appear in court on pain of 100*l.* to be forfeited to the king, and 10*l.* together with damages equivalent to the loss sustained by the want of his evidence to the party aggrieved. 3 Black. Com. 369.

But witnesses ought to have a reasonable time, that their attendance upon the court may be of as little prejudice to themselves as possible; and the court of king's-bench held, that notice at two in the afternoon to attend the sitting that evening at Westminster was too short a time. Str. 510.

Where a witness cannot be present at a trial, he may, by consent of the plaintiff and defendant, or by rule of court, be examined upon interrogatories at the judge's chambers.

No witness is bound to appear to give evidence in a cause unless his reasonable expence is tendered him, and if he appears till such charge is actually paid him, except he both resides and is summoned to give evidence within the bills of mortality.

WOAD, in botany. See Isatis, and Indigo.

WOLF. See Canis.

WOLF-HOLES, in the defence of places, are round holes, generally about two or three feet in diameter at the top, one at bottom, and two and a half deep, dug in the front of any work. Sometimes a sharp-pointed stake or two are fixed at the bottom, and covered with very thin planks, and green sods; consequently the enemy, on advancing, fall in, and are put into confusion.

WOLFRAM, an ore of tungsten, is found in different parts of Germany, in Sweden, Britain, France, and Spain; and almost constantly accompanied by ores of tin. It occurs both massive and crystallized. The primitive form of its crystals, according to the observations of Mr. Hauy, is a rectangular parellelopiped, whose length is 8.66, whose breadth is five, and thickness 4.33. It is not common, however, to find crystals of this perfect form in many cases: the angles, and sometimes the edges, of the crystal are wanting; owing, as Mr. Hauy has shewn, to the superposition of plates, whose edges or angles decrease according to a certain law.

Colour brown or brownish black. Streak reddish brown. Powder stains paper with the same colour. Texture foliated. Easily separated into plates by percussion. Specific gravity from 7. to 7.3. Moderately electric by communication. Not magnetic. Infusible by the blowpipe. Forms with borax a greenish globule, and with microcosmic salt a transparent globule of a deep red.

The specimen of this ore, examined by Messrs. d'Elhuyarts, was composed of

65	oxide of tungsten
22	oxide of manganese
13	oxide of iron
100.	

Another specimen from Puy-les-Mines in France, analysed by Vauquelin and Hecht, contained

67.00	oxide of tungsten
18.00	black oxide of iron
6.25	black oxide of manganese
1.50	silica
7.25	oxide of the iron and manganese
100.00	

WOMEN. By the 26 G. II. c. 33, no suit shall be had in any ecclesiastical court, to compel a celebration of marriage in facie ecclesiæ, by reason of any contract of matrimony whatsoever, whether per verba de præsenti, or per verba de futuro: and the marriage of any person under the age of twenty-one, without the consent of parents or guardians, shall be null and void.

By 20 H. VI. c. 9 peeresses shall be tried as peers for treason or felony.

And by stat. 3 W. c. 9, a woman being convicted of an offence, for which a man may have his clergy, shall suffer the same punishment that a man should suffer, who has the benefit of his clergy allowed; that is, shall be burnt in the hand, and further kept in prison as the court shall think fit, not exceeding one year.

But she shall be only once intitled to the benefit of the said statute.

WOOD, a solid substance, whereof the trunks and branches of trees consist. See the articles Tree, Trunk, Branch, Underwood, Plants, *physiology of*, Timber, &c.

The wood lies immediately under the bark, and forms by far the greatest part of the trunk and large branches of trees. It consists of concentric layers, the number of which increases with the age of the part. Each of these layers, as Mr. Duhamel ascertained, may be separated into several thinner layers, and these are composed chiefly of longitudinal fibres. Hence the reason that wood may be much more easily split asunder than cut across.

The wood, when we inspect it with attention, is not, through its whole exent, the same; the part of it next the bark is much softer and whiter, and more juicy than the rest, and has for that reason obtained a particular name; it has been called the alburnum or aubier. The perfect wood is browner, and harder, and denser, than the alburnum, and the layers increase in density the nearer they are to the centre. Sir John Hill gave to the innermost layer of wood the name of corona; or rather he gave this name to a thin zone which, according to him, lies between the wood and the pith.

Mortimer observes that all kinds of wood are to be preserved from insects and from many other occasions of decay, by oily substances, particularly the essential oils of vegetables. Oil of spike is excellent; and oil of juniper, turpentine, or any other of this kind, will serve the purpose; these will preserve tables, instruments, &c. from being eaten to pieces by these vermin; and linseed-oil will serve, in many cases, to the same purpose; probably nut-oil will do also, and this is a sweeter oil, and a better varnish for wood.

Some of the West Indian trees afford a sort of timber which, if it would answer in point of size, would have great advantages over any of the European wood in ship-building for the merchant-service, no worm ever touching this timber. The acajou, or tree which produces the cashew-nut, is of this kind; and there is a tree of Jamaica, known by the name of the white wood, which has exactly the same property; and so have many other of their trees.

To season wood expeditiously for sea-service, Mr. Boyle observes, that it has been usual to bake it in ovens.

The art of moulding wood is mentioned by Mr. Boyle as a desideratum in the art of carving. He says, he had been credibly informed of its having been practised at the Hague; and suspects that it might have been performed by some menstruum that softens the wood, and afterwards allows it to harden again, in the manner that tortoise-shell is moulded: or perhaps by reducing the wood into a powder, and then uniting it into a mass with strong but thin glue. And he adds, that, having mixed saw-dust with a fine glue made of isinglass, slightly straining out what was superfluous through a piece of linen, the remainder, formed into a ball, and dried, became so hard as to rebound when thrown against the floor.

The people who work much in wood, and about small works, find a very surprising difference in it, according to the different seasons at which the tree was cut down; and thts not regularly the same in regard to all species, but different in regard to each. The button-mould makers find that the wood of the pear-tree, cut in summer, works toughest; holly, on the contrary, works toughest when cut in winter; box is mellowest when it has been cut in summer, but hardest when cut about Easter; hawthorn works mellow when cut about October, and the service is always tough if cut in summer.

Wood Staining.

To stain wood yellow. Take any white wood, and brush it over several times with the tincture of turmeric root, made by putting an ounce of turmeric, ground to powder, to a pint of spirit, and after they have stood for some days, straining off the tincture. If the yellow colour is desired to have a reddish cast, a little dragon's blood must be added.

A cheaper, but less strong and bright yellow is, by the tincture of French berries made boiling-hot.

Wood may also be stained yellow by means of aqua fortis, which will sometimes produce a very beautiful yellow colour, but at other times a browner. Care must be taken, however, that the aqua fortis is not too strong; otherwise a blackish colour will be the result.

To stain wood red. For a bright red stain for wood, make a strong infusion of Brazil wood in stale urine, or water impregnated with pearl-ashes, in the proportion of an ounce to a gallon; to a gallon of either of which, the proportion of Brazil wood must be a pound, which being put to them, they must stand together for two or three days, often stirring the mixture. With this infusion strained, and made boiling-hot, brush over the wood to be stained till it appears strongly coloured; then, while yet wet, brush it over with alum-water made in the proportion of two ounces of alum to a quart of water.

For a less bright red dissolve an ounce of dragon's blood in a pint of spirit of wine, and brush over the wood with the tincture till the stain appears to be as strong as is desired; but this is, in fact, rather lacquering than staining.

For a pink or rose red, add to a gallon of the above infusion of Brazil wood two additional ounces of the pearl-ashes, and use it as was before directed: but it is necessary, in this case, to brush the wood over with alum-water. By increasing the proportion of pearl-ashes, the red may be rendered yet paler: but it is proper, when more than this quantity is added, to make the alum-water stronger.

To stain wood blue. Wood may be stained blue by means either of copper or indigo.

The method of staining blue with copper is as follows: Make a solution of copper in aqua fortis, and brush it while hot several times over the wood; then make a solution of pearl-ashes in the proportion of two ounces to a pint of water, and brush it hot over the wood stained with the solution of copper, till it is of a perfectly blue colour.

To stain wood green. Dissolve verdigrise in vinegar, or crystals of verdigrise in water, and with the hot solution brush over the wood till it is duly stained.

To stain wood purple. Brush the wood to be stained several times with a strong decoction of logwood and Brazil, made in the proportion of one pound of the logwood, and a quarter of a pound of the Brazil, to a gallon of water, and boiled for an hour or more. When the wood has been brushed over till there is a sufficient body of colour, let it dry, and then be slightly passed over by a solution of one drachm of pearl-ashes in a quart of water. This solution must be carefully used, as it will gradually change the colour from a brown red, which it will be originally found to be, to a dark blue purple, and therefore its effect must be restrained to the due point for producing the colour desired.

To stain wood a mahogany colour. The substances used for staining mahogany colour are madder, Brazil wood, and logwood: each of which produces reddish brown stains, and they must be mixed together in such proportions as will produce the tint required.

To stain wood black. Brush the wood several times over with a hot decoction of logwood. Then having prepared an infusion of galls by putting a quarter of a pound of powdered galls to two quarts of water, and setting them in the sunshine, or any other gentle heat, for three or four days, brush the wood over three or four times with it, and it will be of a beautiful black. It may be polished with a hard brush and shoemakers' black wax.

Wood, *fossile:* whole trees, or parts of them, are very frequently found buried in the earth, and that in different strata; sometimes in stone, but more usually in earth, but sometimes in small pieces loose among gravel. See Petrifaction.

WOODCOCK. See the article Scolopax.

Woodcock-shell, in natural history, the variegated yellowish purpura, with tubercles, and a long beak; and the thorny woodcock-shell is the yellow long-beaked purpura, with long and crooked spines.

WOODLOUSE. See Oniscus.

WOODPECKER. See Picus.

WOOF, among manufacturers, the threads which the weavers shoot across with an instrument called the shuttle. The woof is of different matter, according to the piece to be wrought. In taffety, both woof and warp are silk. In mohairs, the woof is usually wool, and the warp silk. In satins, the warp is frequently flax, and the woof silk.

WOOL, a kind of long, soft, curly hair (see the article Hair), which covers the skin of several of the ruminating animals, but which is particularly cut or shorn from that of the sheep, is in such universal use, that we should think it must be one of those animal substances most accurately known; it is, however, within a few years, that chemists have occupied themselves with examining it. Formerly, they contented themselves with considering it as diffusing a disagreeable smell when it was burned, and as yielding much oil and carbonat of ammonia, by distillation. It had been remarked in common life, that it did not inflame without great difficulty, and that it exhaled a very fetid thick smoke, instead of taking a bright flame. Finally, it was known, that the caustic alkalies easily corroded it, and that it quickly received, and forcibly retained, the colouring matters that were imprinted upon it, so that it deserved the first rank amongst the substances to be dyed. The extremely numerous uses, to which it has been appropriated in a number of arts from time immemorial, had brought all its useful properties to light; but chemistry had considered it only under its most general relation with all the animal matters, without ascertaining any thing specific in it. Berthollet began to occupy himself particularly with it in 1784 and 1785. He has shewn that the caustic alkaline leys dissolve it entirely, and that the acids precipitate it from this solution; in this combination, he has sought the mode of action which the alkalies exert upon animal substances, and he has particularly availed himself of it, for explaining the very remarkable energy which exists between these two matters. In this manner he has especially accounted for the action of the lapis causticus, upon the bodies of animals. He has, moreover, shown that the coal of wool was difficult to be burned, like that of all the animal compounds; that wool, treated by the nitric acid, afforded azotic gas, and oxalic acid, with a fatty matter. Chaptal, applying this solution of wool in the alkalies, to the processes of the manufacture of cloth, has represented it as a soap of great utility for these manufactures, and very well adapted for being substituted instead of that which is fabricated with vegetable oil. Wool has, moreover, been considered as a very bad conductor of caloric; and upon this principle it has been explained, how, by retaining that which exhales from our bodies, it forms the warmest clothing, the best adapted for moderating the severity of the winters. See Hair.

The facts contained in the article to which we refer, will explain all the phenomena, and all the properties which wool presents, in the frequent and advantageous uses to which it is constantly applied. The warmth which it affords as clothing or covering, its impenetrability by water, its fine colouration, the durability and solidity of its dyes, its destruction by the alkalies, the facility with which grease and oils penetrate it, the extension of the spots which are formed upon it, even the use which it has, and the functions which it performs upon the bodies of those animals which are covered with it, and from which we take it in order to clothe ourselves; the adherent and fetid oil; the exudation with which it is impregnated upon the bodies of sheep; the manner in which it defends them against the rain and the water, which are so hurtful to them; its slow combustion; the yellowness and loss of tenacity that are produced in it by long exposure to the air: in a word, all that appertains to its characters, its formation, its use, its so various properties, its destruction, becomes clear and easily conceivable by the distinct determination of its nature, and of its composition.

Wool, either in a raw or manufactured state, has always been the principal of the staple articles of this country. The price of wool was in very early times much higher in proportion to the wages of labour, the rent of land, and the price of butcher's meat, than at present. It was before the time of Edward III. always exported raw, the art of working it into cloth and dyeing being so imperfectly known, that no persons above the degree of working people could go dressed in cloth of English manufacture.

The first steps taken to encourage the manufacture of woollen cloths was by Edward the Third, who procured some good workmen from the Netherlands by means of protection and encouragement. The value of wool was considered as so essentially solid, that taxes were voted in that commodity, reckoning by the number of sacks; and in proportion to the price of the necessaries of life and value of silver, wool was at least three times dearer then than it is now. The manufacturing of cloth being once introduced into the country, the policy of preventing the exportation of the raw material was soon evident; and the first act, was that of H. IV. c. 2., by which the exportation of sheep, lambs, or rams, is forbidden under very heavy penalties.

By stat. 28. Geo. III. all former statutes respecting the exportation of wool and sheep are repealed, and numerous restrictions are consolidated in that statute.

By this act, if any person shall send or receive any sheep on board any vessel, to be carried out of the kingdom, such vessel shall be forfeited, and the person so offending shall forfeit 3*l.* for every sheep, and suffer solitary imprisonment for three months. But wether sheep, by a licence from the collector of the customs, may be taken on board for the use of the ship's company; and every person who shall export any wool, or woollen articles slightly made up, so as easily to be reduced again to wool, or any fuller's earth or tobacco-pipe clay, and every carrier, ship-owner, commander, mariner, or other person, who shall knowingly assist in exporting, or attempting to export, these articles, shall forfeit three shillings for every pound weight, or the sum of 50*l.* in the whole, at the election of the prosecutor, and shall also suffer solitary imprisonment for three months. But wool may be carried coastwise upon being duly entered, and security being given according to the directions of the statute, to the officer of the port whence the same shall be conveyed; and the owners of sheep within five miles of the sea, and ten miles in Kent and Sussex, cannot remove the wool, without giving notice to the officer of the nearest port, as directed by the statute.

Woollen Cloth, *interment in.* By 30 G. II. c. 3. (an act which is required to be given in charge at the assizes and sessions, and to be read four times publicly each year in the church by every parson), no corpse of any person (except of those who die of the plague) shall be buried in any shirt, shift, sheet, or shroud, or any thing made or mingled with flax, hemp, silk, hair, gold, or silver, or in any stuff or thing not made of sheep's wool only; or be put into any coffin lined or faced with any sort of clothier-stuff, or any other thing, made of any other material than sheep's wool only, under penalty of *5l.* to be recovered by distress and sale of the goods and chattels of the party deceased.

Wool-combers. By 35 G. III. c. 124, all those who have served an apprenticeship to the trade of a wool-comber, or who are by law entitled to exercise the same, and also their wives and children, may set up and exercise such trade, or any other trade or business they are apt and able for, in any town or place within this kingdom, without any molestation; nor shall they be removeable from such place by the poor laws.

WORD, in a military sense, signifies signal, token, order; as watch-word, &c.

The Word, / *Watch* Word, is a peculiar word that serves for a token and mark of distinction, given out in the orders of the day in times of peace, but in war every evening in the field, by the general who commands, and in garrison by the governor, or other officer commanding in chief, to prevent surprise, and hinder an enemy, or any treacherous person, from passing backwards and forwards. This watch-word is generally called the parole, and to it is added the countersign. The first is known to all officers and non-commissioned officers, the latter only to the sentinels. The officers that go the rounds, or patroles, exchange the word with the officers on duty; nor must the sentinels let any one pass who has not got the countersign.

Words *of command*, certain terms which have been adopted for the exercise and movement of military bodies, according to the nature of each particular service. Words of command are classed under two principal heads, and consist of those which are given by the chief or commander of a brigade, battalion, or division, and of those which are uttered by the subordinate leaders of troops, &c.

WORD, in language, an articulate sound, representing some idea or conception of the mind. The copiousness of the English language is proved by the following enumeration of the words in Johnson's Dictionary:

Articles			3
Nouns substantive			20409
Adjectives			9053
Pronouns			41
Verbs	active	5445	7880
	neuter	2425	
	passive	1	
	defective (or imperfect)	5	
	auxiliary	1	
	impersonal	3	
Verbal noun			1
Participles			38
Participial	adjectives		125
	nouns		3
Adverbs		496	2592
—— in *ly*		2096	
Prepositions			69
Conjunctions			19
Interjections			68
Total			40301

It must be remarked, however, that in this list many of the compound words are not reckoned; that the participles are those only having no verbs to which they may be referred, as *beloved*; that though so few verbal and participial nouns are stated by Johnson, yet every active verb may supply one of the former description, and every verb one of the latter; and that both these (verbal and participial nouns) seem to be merely different applications of a true gerund.

WORDS, which may be taken or interpreted by law in a general or common sense, ought not to receive a strained or unusual construction: and ambiguous words are to be construed so as to make them stand with law and equity, and not to be wrested to do wrong. 2 Lill. 711. See 16 Vin. Abr.

Words, Defamatory, are in some cases indictable, as calling a justice of the peace a rogue; and in others actionable, as to say such an attorney is a rogue.

WORKING IN HARVEST. A person may go abroad to work in harvest, carrying with him a certificate from the minister, and one churchwarden or overseer, that he has a dwelling-house or place, in which he inhabits, and has left wife and children, or some of them, there (or otherwise as his condition shall require), and declaring him an inhabitant there. A person carrying such certificate with him, shall not be apprehended under the stat. 17 G. II. c. 5. commonly called the vagrant act.

WORMS. See Vermes, and Medicine.

WORMWOOD. See Artemisia.

WOUND. See Surgery.

WRECK, such goods as after a shipwreck are cast upon the land by the sea, and left there within some county, for they are not wrecks so long as they remain at sea, being within the jurisdiction of the admiralty.

Various statutes have been made relative to wreck, which was formerly a perquisite belonging to the king, or by special grant to the lord of the manor; it is now, however, held, that if proof can be made of the property of any of the goods or lading which come to shore, they shall not be forfeited as wreck.

By the 3 Ed. c. 4, the sheriff of the county shall be bound to keep the goods a year and a day; that if any man can prove a property in them, either in his own right, or by right of representation, they shall be restored to him without delay.

By stat. 26. G. II. c. 19, plundering any vessel either in distress or wreck, and whether any living creature is on board or not, or preventing the escape of any person that endeavours to save his life, or putting out false lights to bring any vessel into danger, are all declared to be capital felonies; and by this statute, pilfering any goods cast ashore is declared to be petty larceny.

WREN. See Motacilla.

WRIST. See Anatomy.

WRIT, is the king's precept, by which any thing is commanded touching a suit or action; as the defendant or tenant to be summoned, a distress to be taken, a disseisin to be redressed, &c. And these writs are diversly divided; some in respect of their order, or manner of granting, are termed original, and some judicial.

Original writs, are those that are sent out for the summoning of the defendant in a personal, or the tenant in a real action, before the suit begins, or rather to begin the suit.

The judicial writs are those which are sent out by order of the court where the cause depends, upon occasion after the suit is begun.

Original writs are issued out in the court of chancery, for the summoning a defendant to appear, and are granted before the suit is begun, to begin the same: and judicial writs issue out of the court where the original is returned, after the suit began. The original bear date in the name of the king; but the judicial writs bear teste in the name of the chief justice.

Writ of Assistance, issues out of the exchequer, to authorize any person to take a constable, or other public officer, to seize goods or merchandize prohibited and uncustomed.

It is also a writ issuing out of the chancery to give a possession.

Writ of Inquiry of Damages, a judicial writ that issues out to the sheriff, upon a judgment by default, in action of the case, covenant, trespass, trover, &c. commanding him to summon a jury to inquire what damages the plaintiff has sustained occasione præmissiorum; and when this is returned with the inquisition, the rule for judgment is given upon it: and if nothing is said to the contrary, judgment is thereupon entered. 2 Lill. Abr. 721.

A writ of inquiry of damages, is a mere inquest of office, to inform the conscience of the court; who, if they please, may themselves assess the damages. And it is accordingly the practice, in actions upon promissory notes and bills of exchange, instead of executing a writ of inquiry, to apply to the court for a rule to shew cause, why it should not be referred to the master to see what is due, &c. which rule is made absolute unless good cause is shewn to the contrary.

WRITER *of the tallies,* an officer of the exchequer, being clerk to the auditor of the receipt, who writes upon the tallies, the whole letters of the teller's bill.

WULFERRIA, a genus of plants of the class and order diandria monogynia. The corolla is tubular, ringent, with the upper lip short: calyx five-parted; capsules two-celled, four-valved. There is one species, a herb of Carinthia.

WURMBEA, a genus of plants of the class and order hexandria trigynia. The corolla is six-parted, with an hexangular tube; filaments inserted into the throat. There are three species, herbs of the Cape.

X.

X, or x, the twenty-second letter of our alphabet. In numerals it expresses 10, whence in old Roman manuscripts it is used for denarius; and as such seems to be made of two V's placed one over the other. When a dash is added over it, thus $\bar{X}$, it signifies ten thousand.

XANTHE, a genus of plants of the class and order dioecia syngenesia. The flowers are dioecious; the calyx five-parted; corolla 5-6 petalled. There are two species, shrubs of Guiana.

XANTHIUM, a genus of plants of the class monœcia, order pentandria, and arranged in the natural classification under the 49th order, compositæ. The male flowers are composite, common calyx imbricated; corollulæ monopetalous, tubular, quinquefid. Female: calyx involucrum of two leaves, containing two flowers; corolla 0; drupa dry, prickly; nucleus bilocular. There are five species, only one of which is a native of Britain, the strumarium or less burdock. The stem of this plant is a foot and a half high, thick, often spotted; leaves heart-shaped, lobed, on long footstalks. Flowers, male and female, many together, in the alæ of the leaves. The leaves are bitter and astringent. A decoction of the whole plant affords a showy yellow colour, but it is better if only the flowers are used. Horses and goats eat it: cows, sheep, and swine, refuse it.

XANTHIORZA, a genus of plants of the class and order pentandria polygamia. There is no calyx; the petals five; nectarines five, pedicelled; capsules five, one-seeded. There is one species, a shrub of North America.

XANTHOXYLUM, the tooth-ache tree, a genus of plants of the class and order diœcia pentandria. The calyx is five-parted; no corolla; fem. pist. five; capsules five, one-seeded. There is one species, a tree of Jamaica.

XERANTHEMUM, a genus of the syngenesia polygamia superflua class of plants; the compound flower of which is unequal, and consists of many tubulous hermaphrodite floscules placed on the disc, and also a few female tubulated ones on the verge; the seeds are oblong, coronated, and contained in the cup. There are twenty-seven species.

XIMENIA, a genus of plants of the class and order pentandria monogynia. The calyx is a perianthium, composed of three small, cordated, and deciduous leaves; the corolla is formed of four petals, of a campanulated figure, divided at the edge into three erect, oblong, obtuse segments; the germen is small, and of a suboval figure; the fruit is an oval drupe, containing one cell; the seed is oval, unilocular, and smooth. There are three species, trees of the West Indies.

XIPHIAS, in zoology, the sword-fish, a genus of fishes belonging to the order of apodes. The upper jaw terminates in a long sword-shaped rostrum, from which it is called the sword-fish: there are no teeth in the mouth; the gill membrane has eight rays; and the body is somewhat cylindrical. There is but one species, viz. the gladius, found in the European ocean. This fish sometimes frequents our coasts, but is much more common in the Mediterranean sea, especially in the part that separates Italy from Sicily, which has been long celebrated for it: the promontory Pelorus, now Capo di Faro, was a place noted for the resort of the xiphias, and possibly the station of the speculatores, or the persons who watched and gave notice of the approach of the fish.

The antient method of taking them is particularly described by Strabo, and agrees exactly with that practised by the moderns. A man ascends one of the cliffs that overhang the sea: as soon as he spies the fish, he gives notice, either by his voice or by signs, of the course it takes. Another, that is stationed in a boat, climbs up the mast, and on seeing the sword-fish, directs the rowers towards it. As soon as he thinks they are got within reach, he descends, and taking a spear in his hand, strikes it into the fish; which, after wearying itself with its agitation, is seized and drawn into the boat. It is much esteemed by the Sicilians, who buy it up eagerly, and at its first coming into season, give about six-pence English per pound. The season lasts from May till August. The antients used to cut this fish into pieces and salt it; whence it was called Tomus Thurianus, from Thurii, a town in the bay of Tarentum, where it was taken and cured.

The sword-fish is said to be very voracious, and that it is a great enemy to the tunny, who (according to Belon) are as much terrified at it as sheep are at the sight of a wolf. It is a great enemy to the whales, and frequently destroys them.

XIPHIDIUM, a genus of plants of the class and order triandria monogynia. The corolla is six-petalled, equal; capsules superior, three-celled, many-seeded. There is one species, a herb of the West Indies.

XYLO-ALOES, or Aloe-wood, in pharmacy. See Excoecaria.

XYLOCARPUS, a genus of plants of the class and order octandria monogynia. The calyx is four-toothed; the corolla four-petalled; nectarium eight-cleft; filaments inserted in nect.; drupe four or five-grooved; nuts eight or ten. There is one species, a tree of the East Indies.

XYLOMELUM, a genus of plants of the class and order tetrandria monogynia. The ament. is with a simple scale; petals four, staminiferous; stigma club-shaped, obtuse. There is one species, of no note.

XYLOPHYLLA, a genus of plants of the class and order pentandria trigynia. The calyx is five-parted, coloured; corolla none; one stigma, jagged; capsule three-celled; seeds two. There are seven species, shrubs of the West Indies.

XYLOPIA, a genus of plants of the class and order polyandria polygynia. The calyx is three-leaved; petals six; capsule one or two seeded, four-cornered, two-valved; seeds arilled. There are three species, trees of the West Indies.

XYLOSMA, a genus of plants of the class and order diœcia polyandria. The calyx is four or five parted; corolla none; male stamina twenty to fifty; female style scarcely any; stigma trifid; berry dry; seeds two, three-sided. There are two species.

XYRIS, a genus of the triandria monogynia class of plants, the flower of which consists of three plain, patent, large, crenated petals, with narrow ungues, of the length of the cup. The fruit is a roundish, trilocular, trivalvular capsule, within the cup, with a great number of very small seeds. There are three species.

Y.

Y, the twenty-third letter of our alphabet. Y is a numeral, signifying 150, or according to Baronius, 159; and with a dash at top, as $\bar{Y}$, it signified 150,000.

YACHT. This word is taken from the Dutch. It is a small ship with one deck, carrying four, eight, or twelve guns, and thirty or forty men. Yachts, in general, are from thirty to 160 tons; contrived and adorned both withinside and without, for carrying state passengers. They answer the purposes of business as well as pleasure, being remarkably good sailers.

YARD. See Measure.

Yards *of a ship*, are those long pieces of timber which are made a little tapering at each end, and are fitted each athwart its proper mast, with the sails made fast to them, so as to be hoisted up, or lowered down, as occasion serves. They have their names from the masts to which they belong. As for the length of the main-yard, it is usually five-sixths of the length of the keel, or six-sevenths of the length of the main-mast. Their thickness is commonly three quarters of an inch for every yard in length. The length of the main-top-yard is two-fifths of the main-yard; and the fore-yard four-fifths of it. The sprit-sail-yard, and cross-jack-yard, are half the mizen-yard; and the thickness of the mizen-yard and spritsail-yard is half an inch for every yard in length. All small yards are half the great yards from cleat to cleat. When a yard is down a portlast, it gives the length of all top-sail-sheets, lifts, ties, and bunt-lines, as also of the leech-lines and halliards, measuring from the hounds to the deck: and when it is hoisted, it gives the length of clew-lines, clew-garnets, braces, tackles, sheets, and bow-lines.

There are several sea-terms relating to the management of the yards; as, square the yards; that is, see that they hang right across the ship, and no yard-arm traversed more than another: top the yards, that is, make them stand even. To top the main and fore-yards, the clew-lines are the most proper;

but when the top-sails are stowed, then the top-sail-sheets will top them.

Yard-arm is that half of the yard that is on either side of the mast, when it lies athwart the ship.

YARN, wool or flax spun into thread, of which they weave cloth.

Yarn is ordered after the following manner: After it has been spun upon spindles, spools, or the like, they reel it upon reels, which are hardly two feet in length, and have but two contrary cross-bars, being the best, and the least liable to ravelling. In reeling of fine yarn, the better to keep it from ravelling, you must, as it is reeled, with a tye-band of big twist, divide the slipping or skain into several leys, allowing to every ley eighty threads, and twenty leys to every slipping, if the yarn is very fine; otherwise less of both kinds. The yarn being spun, reeled, and in the slippings, the next thing is to scour it. In order to fetch out the spots, it should be laid in lukewarm water for three or four days, each day shifting it once, wringing it out, and laying it in another water of the same nature: then carry it to a well or brook, and rinse it till nothing comes from it but pure clean water: that done, take a bucking-tub, and cover the bottom with very fine ashen ashes; and then having opened and spread the slippings, lay them on those ashes, and put more ashes above, and lay in more slippings, covering them with ashes as before; and thus lay one upon another, till all the yarn is put in: afterwards cover up the uppermost yarn with a bucking cloth, and, in proportion to the size of the tub, lay in it a peck or two more of ashes: this done, pour upon the uppermost cloth a great deal of warm water, till the tub can receive no more, and let it stand so all night. Next morning you are to set a kettle of clean water on the fire; and when it is warm, pull out the spiggot of the bucking tub, to let the water run out of it, into another clean vessel; as the bucking tub wastes, fill it up again with the warm water on the fire: and as the water on the fire wastes, so likewise fill that up with the lye that comes from the bucking-tub; ever observing to make the lye hotter and hotter, till it boils: then you must, as before, ply it with the boiling lye at least four hours together, which is called the driving of a buck of yarn.

All this being done, for the whitening of it, you must take off the bucking cloth; then putting the yarn with the lye-ashes into large tubs, with your hands labour the yarn, ashes, and lye, pretty well together; afterwards carry it to a well, or river, and rinse it clean; then hang it upon poles in the air all day, and in the evening take the slippings down, and lay them in water all night; the next day hang them up again, and throw water upon them as they dry, observing to turn that side outermost which whitens slowest. After having done this for a week together, put all the yarn again into a bucking-tub, without ashes, covering it as before with a bucking cloth; lay thereon good store of fresh ashes, and drive that buck, as before, with very strong boiling lye, for half a day, or more; then take it out, and rinse it, hanging it up, as before, in the day-time, to dry, and laying it in water at night, another week: lastly, wash it over in fair water, and so dry it up. Your yarn being thus scoured and whitened, wind it up into round balls of a moderate size.

YEAR, in the full extent of the word, is a system or cycle of several months, usually 12. Others define year, in the general, a period or space of time, measured out by the revolution of some celestial body in its orbit. Thus, the time in which the fixed stars make a revolution, is called the great year; and the times in which Jupiter, Saturn, the Sun, Moon, &c. complete their courses, and return to the same point of the zodiac, are respectively called the years of Jupiter and Saturn, and the solar and lunar years, &c.

As year denoted originally a revolution, and was not limited to that of the Sun; accordingly we find by the oldest accounts, that people have, at different times, expressed other revolutions by it, particularly that of the Moon; and consequently that the years of some accounts, are to be reckoned only months, and sometimes periods of 2, or 3, or 4 months. This will help us greatly in understanding the accounts that certain nations give of their own antiquity, and perhaps of the age of men. We read expressly, in several of the old Greek writers, that the Egyptian year, at one period, was only a month; and we are farther told that at other periods it was three months, or four months; and it is probable that the children of Israel followed the Eglptian account of their years. The Egyptians talked, almost 2000 years ago, of having accounts of events 48,000 years distance. A great deal must be allowed to fallacy, on the above account; but beside this, the Egyptians had, in the time of the Greeks, the same ambition which the Chinese have at present; and wanted to pass themselves upon that people, as these do upon us, for the oldest inhabitants of the earth. They had recourse also to the same means; and both the present and the early impostors have pretended to antient observations of the heavenly bodies, and recounted eclipses in particular, to vouch for the truth of their accounts. Since the time in which the solar year, or period of the earth's revolution round the sun, has been received, we may account with certainty; but for those remote ages, in which we do not know with certainty what is meant by the term year, it is impossible to form any conjecture of the duration of time in the accounts. The Babylonians pretend to an antiquity of the same romantic kind; they talk of 47,000 years in which they had kept observations; but we may judge of these as of the others, and of the observations as of the years. The Egyptians speak of the stars having four times altered their courses in that period which they claim for their history, and that the Sun set twice in the east. They were not such perfect astronomers, but, after a roundabout voyage, they might perhaps mistake the east for the west when they came in.

Year, or *solar year*, properly, and by way of eminence so called, is the space of time in which the sun moves through the twelve signs of the ecliptic. This, by the observations of the best modern astronomers, contains 365 days, 5 hours, 48 minutes, 48 seconds; the quantity assumed by the authors of the Gregorian calendar is 365 days, 5 hours, 49 minutes. But in the civil or popular account, this year contains only 365 days; except every fourth year, which contains 366.

The vicissitude of seasons seems to have given occasion to the first institution of the year. Man, naturally curious to know the cause of that diversity, soon found it was the proximity and distance of the sun; and therefore gave the name year to the space of time in which that luminary performed his whole course, by returning to the same point of his orbit. According to the accuracy in their observations, the year of some nations was more perfect than that of others, but none of them quite exact, nor whose parts did not shift with regard to the parts of the sun's course.

According to Herodotus, it was the Egyptians who first formed the year, making it to contain 360 days, which they subdivided into 12 months, of 30 days each. Mercury Trismegistus added five days more to the account. And on this footing it is said that Thales instituted the year among the Greeks; though that form of the year did not hold throughout all Greece. Also, the Jewish, Syrian, Roman, Persian, Ethiopic, Arabic, &c. years, were all different. In fact, considering the imperfect state of astronomy in those ages, it is no wonder that different people should disagree in the calculation of the sun's course. We are even assured, that the Egyptian year itself was at first very different from that now represented.

The solar year is either astronomical or civil.

The astronomical solar year, is that which is determined precisely by astronomical observations; and is of two kinds, tropical, and sidereal or astral.

Tropical, or natural year, is the time the sun takes in passing through the zodiac; which, as before observed, is 365 days, 5 hours, 48 minutes, 48 seconds; or 365 days, 5 hours, 49 minutes. This is the only proper or natural year, because it always keeps the same seasons to the same months.

Sidereal or astral year, is the space of time the sun takes in passing from any fixed star, till his return to it again. This consists of 365 days, 6 hours, 9 minutes, 17 seconds; being 20 minutes, 29 seconds, longer than the true solar year.

Lunar year, is the space of twelve lunar months. Hence, from the two kinds of synodical lunar months, there arise two kinds of lunar years; the one astronomical, the other civil.

Lunar astronomical year, consists of twelve lunar synodical months; and therefore contains 354 days, 8 hours, 28 minutes, 38 seconds, and is therefore 10 days, 21 hours, 0 minutes, 10 seconds, shorter than the solar year; a difference which is the foundation of the epact.

Lunar civil year, is either common or embolismic.

The common lunar year consists of twelve lunar civil months, and therefore contains 354 days. And

The embolismic or intercalary lunar year, consists of 13 lunar civil months, and therefore contains 384 days.

Thus far we have considered years and months, with regard to astronomical principles, upon which the division is founded. By this, the various forms of civil years that have formerly obtained, or that do still obtain, in different nations, are to be examined.

Civil year, is that form of year which every nation has contrived or adopted, for computing their time by. Or the civil is the tropical year, considered as only consisting of a certain number of whole days; the odd hours and minutes being set aside, to render the computation of time, in the common occasions of life, more easy. As the tropical year is 365 days, 5 hours, 49 minutes, or almost 365 days, 6 hours, which is 365 days and a quarter; therefore if the civil year is made 365 days, every fourth year it must be 366 days, to keep nearly to the course of the sun. And hence the civil year is either common or bissextile. The

Common civil year, is that consisting of 365 days; having seven months of thirty-one days each, four of thirty days, and one of twenty-eight days; as indicated by the following well-known memorial verses:

Thirty days hath September,
April, June, and November;
February twenty-eight alone,
And all the rest have thirty-one.

Bissextile or leap-year, consists of 366 days, having one day extraordinary, called the intercalary, or bissextile day, which takes place every fourth year. This additional day to every fourth year, was first introduced by Julius Cæsar; who, to make the civil years keep pace with the tropical ones, contrived that the six hours which the latter exceeded the former, should make one day in four years, and be added between the 24th and 23d of February, which was their sixth of the calends of March; and as they then counted this day twice over, or had bis sexto calendas, hence the year itself came to be called bis sextus, and bissextile.

Among us, however, the intercalary day is not introduced by counting the 23d of February twice over, but by adding a day at the end of that month, which therefore in that year contains 29 days.

The civil or legal year, in England, formerly commenced on the day of the annunciation, or 25th of March; though the historical year began on the day of the Circumcision, or 1st of January; on which day the German and Italian year also begins. The part of the year between these two terms was usually expressed both ways; as 1745-6, or $174\frac{5}{6}$. But by the act for altering the style, the civil year now commences with the 1st of January.

Antient Roman year. This was the lunar year, which, as first settled by Romulus, contained only ten months, of unequal numbers of days, in the following order: viz.

March 31, April 30, May 31, June 30, Quintilis 31, Sextilis 30, September 30, October 31, November 30, December 30, in all 304 days; which came short of the true lunar year by 50 days, and of the solar by 61 days. Hence the beginning of Romulus's year was vague, and unfixed to any precise season; to remove which inconvenience, that prince ordered so many days to be added yearly as would make the state of the heavens correspond to the first month, without calling them by the name of any month.

Numa Pompilius corrected this irregular constitution of the year, composing two new months, January and February, of the days that were used to be added to the former year. Thus Numa's year consisted of twelve months, of different days, as follow; viz.

January	29;	February	28;	March	31;
April	29;	May	31;	June	29;
Quintilis	31;	Sextilis	29;	September	29;
October	31;	November	29;	December	29;

in all 355 days; therefore exceeding the quantity of a lunar civil year by one day; that of a lunar astronomical year by 15 hours, 11 minutes, 22 seconds; but falling short of the common solar year by 10 days; so that its beginning was still vague and unfixed.

Numa, however, desiring to have it begin at the winter solstice, ordered 22 days to be intercalated in February every 2d year, 23 every 4th, 22 every 6th, and 23 every 8th year.

But this rule failing to keep matters even, recourse was had to a new way of intercalating; and instead of 23 days every 8th year, only 15 were to be added. The care of the whole was committed to the pontifex maximus; who, however, neglecting the trust, let things run to great confusion. And thus the Roman year stood till Julius Cæsar reformed it.

Julian Year. This is in effect a solar year, commonly containing 365 days; though every 4th year, called bissextile, it contains 366. The months of the Julian year, with the number of their days, stood thus:

January	31;	February	28;	March	31;
April	30;	May	31;	June	30;
July	31;	August	31;	September	30;
October	31;	November	30;	December	31.

But every bissextile year had a day added in February, making it then to contain 29 days.

The mean quantity therefore of the Julian year is $365\frac{1}{4}$ days, or 365 days, 6 hours; exceeding the true solar year by somewhat more than 11 minutes; an excess which amounts to a whole day in almost 131 years. Hence the times of the equinoxes go backward, and fall earlier by one day in about 130 or 131 years. And thus the Roman year stood, till it was farther corrected by pope Gregory.

For settling this year, Julius Cæsar brought over from Egypt, Sosigenes, a celebrated mathematician; who, to supply the defect of 67 days, which had been lost through the neglect of the priests, and to bring the beginning of the year to the winter solstice, made one year to consist of 15 months, or 445 days; on which account, that year used to be called annus confusionis, or the year of confusion.

Gregorian Year. This is the Julian year corrected by this rule, viz. that instead of every secular or 100th year being a bissextile, as it would be in the former way, in the new way three of them are common years, and only the 4th is bissextile.

The error of 11 minutes in the Julian year, by continual repetition, had accumulated to an error of 13 days from the time when Cæsar made his correction; by which means the equinoxes were greatly disturbed. In the year 1582, the equinoxes were fallen back 10 days, and the full moons four days, more backward than they were in the time of the Nicene council, which was in the year 325; viz. the former from the 20th of March to the 10th, and the latter from the 5th to the 1st of April. To remedy this increasing irregularity, pope Gregory the 13th, in the year 1582, called together the chief astronomers of his time, and concerted this correction, throwing out the 10 days abovementioned. He exchanged the lunar cycle for that of the epacts, and made the 4th of October of that year to be the 15th; by that means restoring the vernal equinox to the 21st of March. It was also provided, by the omission of three intercalary days in 400 years, to make the civil year keep pace nearly with the solar year, for the time to come.

In the year 1700, the error of 10 days was grown to 11; upon which, the protestant states of Germany, to prevent farther confusion, adopted the Gregorian correction. And the same was accepted also in England in the year 1752, when 11 days were thrown out after the 2d of September that year, by accounting the 3d to be the 14th day of the month; calling this the new style, and the former the old style. And the Gregorian, or new style, is now in like manner used in most countries of Europe.

Yet this last correction is still not quite perfect; for as it has been shewn that in four centuries, the Julian year gains 3 days, 2 hours, 40 minutes; and as it is only the three days that are kept out of the Gregorian year, there is still an excess of 2 hours 40 minutes in four centuries, which amounts to a whole day in 36 centuries, or in 3600 years. See Calendar, &c.

Egyptian Year, called also the year of Nabonassar, on account of the epoch of Nabonassar, is the solar year of 365 days, divided into 12 months, of 30 days each, beside 5 intercalary days, added at the end. The order and names of these months are as follow:

1. Thoth;	2. Paophi;	3. Athyr;
4. Chojac;	5. Tybi;	6. Mecheir;
7. Phamenoth;	8. Pharmuthi;	9. Pachon;
10. Pauni;	11. Epiphi;	12. Mesori.

As the Egyptian year, by neglecting the 6 hours, in every 4 years loses a whole day of the Julian year, its beginning runs through every part of the Julian year in the space of 1460 years; after which, they meet again; for which reason it is called the erratic year. And because this return to the same day of the Julian year, is performed in the space of 1460 Julian years, this circle is called the Sothic period.

This year was applied by the Egyptians to civil uses, till Anthony and Cleopatra were defeated; but the mathematicians and astronomers used it till the time of Ptolomy, who made use of it in his Almagest; so that the knowledge of it is of great use in astronomy, for comparing the antient observations with the modern.

The antient Egyptians, we are told by Diodorus Siculus, measured their years by the course of the moon. At first they were only one month, then 3, then 4, like that of the Arcadians; and then 6, like that of the people of Acarnania. Those authors add, that it is on this account that they reckon such a vast number of years from the beginning of the world; and that in the history of their kings, we meet with some who lived 1000 or 1200 years. By such means many account for the great ages of the antient patriarchs; expounding the gradual decrease in their ages, by the successive increase of the number of months in their years.

Upon the Egyptians being subdued by the Romans, they received the Julian year, though with some alteration; for they still retained their antient months, with the five additional days; and every fourth year they intercalated another day, for the 6 hours, at the end of the year, or between the 28th and 29th of August. Also, the beginning of their year, or the first day of the month Thoth, answered to the 29th of August of the Julian year, or to the 30th if it happened to be leap-year.

The antient Greek year, was a lunar year, consisting of 12 months, which at first had each 30 days, then alternately 29 and 30 days, computed from the first appearance of the new moon; with the addition of an embolismic month of 30 days, every 3d, 5th, 8th, 11th, 14th, 16th, and 19th year of a cycle of 19 years; in order to keep the new and full moons to the same terms or seasons of the year.

Their year commenced with that new moon which was nearest to the summer solstice. And the order of the months, with the number of their days, were as follow: 1. Εκατομβαιων, of 29 days; 2. Μηταγειτνιω 30; 3. Βοηδρομιων 29; 4. Μαιμακτηριων 30; 5. Πυανεψιων 29; 6 Ποσειδεων 30; 7. Γαμηλιων 29; 8. Ανθεστηριων 30; 9. Ελαφηβολιων 29; 10. Μουνυχιων 30: 11. Θαργηλιων; 12. Σκιροφοριων 30. But many of the Greek nations had other names for their months.

The ancient Jewish year is a lunar year, usually consisting of 11 months, containing alternately 30 and 29 days. And it was made to agree with the solar year, by adding 11, and sometimes 12 days, at the end of the year, or by an embolismic month. The order and quantities of the months were as follow; 1. Nisan or Abib, 30 days; 2. Jiar or Zius, 29; 3. Siban or Sievan 30; 4. Thamuz or Tamuz 29; 5. Ab 30; 6. Elul 29; 7. Tisri or Ethanim 30; 8. Marchesvam or Bul 29; 9. Cisleu 30; 10. Tebeth 29; 11. Sabat or Schebeth 30; 12. Adar 30, in the embolismic year, but 29 in the common year. Note, in the defective year, Cisleu was only 29 days; and in the redundant year, Marchesvam was 30.

The modern Jewish year is likewise lunar, consisting of 12 months in common years, but of 13 in embolismic years; which, in a cycle of 19 years, are the 3d, 6th, 8th, 11th, 14th, 17th, and 19th. Its beginning is fixed to the new moon next after the autumnal equinox. The names and order of the months, with the number of the days, are as follow: 1. Tisri 30 days; 2. Marchesvam 29; 3. Cisleu 30; 4. Tebeth 29; 5. Schebeth 30; 6. Adar 29; 7. Veadar, in the embolismic year, 30; 8. Nisan 30; 9. Ilar 29; 10. Sivan 30; 11. Thamuz 29; 12. Ab, 30; 13. Elul 29.

The Syrian year, is a solar one, having its beginning fixed to the beginning of October in the Julian year; from which it only differs in the names of the months, the quantities being the same, as follow: 1. Tishrin, answering to our October, and containing 31 days; 2. Latter Tishrin, containing, like November, 30 days; 3. Canun 31: 4. Latter Canun 31; 5. Shabat 28, or 29 in a leap year; 6. Adar 31; 7. Nisan 30; 8. Aiyar 31; 9. Haziram 30; 10. Thamuz 31; 11. Ab 31; 12. Elul 30.

The Persian year, is a solar one, of 365 days, consisting of 12 months of 30 days each, with 5 intercalary days added at the end. The months are as follow: 1. Asrudia meh; 2. Ardihascht meh; 3. Cardi meh; 4. Thir meh; 5. Merded meh; 6. Schabarir meh; 7. Mehar meh; 8. Aben meh; 9. Adar meh; 10. Di meh; 11. Behen meh; 12. Assirer meh. This year is the same as the Egyptian Nabonassarean, and is called the Yesdegerdic year, to distinguish it from the fixed solar year, called the Gelalean year, which the Persians began to use in the year 1079, and which was formed by an intercalation, made six or seven times in four years, and then once every 5th year.

The Arabic, Mahometan, and Turkish year, called also the year of the Hegira, is a lunar year, equal to 354 days, 8 hours, 48 minutes, and consists of 12 months, containing alternately 30 and 29 days: although sometimes it contains 13 months; the names &c. being as follow: 1. Muharram of 30 days; 2. Saphar 29; 3. Rabia 30; 4. Latter Rabia 29; 5. Jomada 30; 6. Latter Jomada 29; 7. Rajab 30; 8. Shaaban 29; 9. Ramadan 30; 10. Shawal 29; 11. Dulkaadah 30; 12. Dulheggia 29, but in the embolismic year 30. An intercalary day is added every 2d, 5th, 7th, 10th, 13th, 15th, 18th, 21st, 24th, 26th, 29th, in a cycle of 29 years. The months commence with the first appearance of the new moons after the conjunctions.

Ethiopic year, is a solar year perfectly agreeing with the Actiac, except in the names of the months, which are: 1. Mascaram; 2. Tykympt; 3. Hydar; 4. Tyshas; 5. Tyr; 6. Jacatil; 7. Magabit; 8. Mijazia; 9. Ginbat; 10. Syne; 11. Hamel; 12. Hahase. Intercalary days 5. It commences with the Egyptian year, on the 29th of August of the Julian year.

YESDEGERDIC Year. See Persian Year.

Year and day, is a time that determines a right in many cases; and in some works an usurpation, and in others a prescription; as in case of an estray, if the owner, proclamation being made, challenges it not within the time, it is forfeited.

So is the year and day given in case of appeal; in case of descent after entry or claim, if no claim upon a fine or writ of right at the common law: so of a villain remaining in ancient demesne; of a man sore bruised or wounded; of protections; essoins in respect of the king's service; of a wreck; and divers other cases. Co. 6. Rep. Fol. 107.

Year books, reports in a regular series, from Ed. II. inclusive, to the time of Henry VIII., which were taken by the prothonotaries of the court, at the expence of the crown, and published annually.

Year day and waste, is a part of the king's prerogative whereby he challenges the profits of their lands and tenements for a year and a day, that are attainted of petty treason or felony; whoever is lord of the manor where the lands or tenements belong; and not only so, but in the end may waste the tenements, destroy the houses, root up the woods, garden, and pasture, and plough up the meadows, except the lord of the fee agrees with him for redemption of such waste, afterward restoring it to the lord of the fee. Staundf. Prærog. c. 16.

YEARS, *estate for*. Tenant for term of years, is where a man lets lands or tenements to another, for a certain term of years agreed upon between the lessor and lessee; and when the lessee enters by force of the lease, then he is tenant for term of years. Litt. Sect. 58.

If tenements are let to a man for the term of half a year, or for a quarter of a year, or any less time; this lessee is respected as tenant for years, and is styled so in some legal proceedings; a year being the shortest term, which the law in this case takes notice of. Litt. Sect. 67.

Generally, every estate which must expire at a period certain and prefixed, by whatever words created, is an estate for years; and therefore this estate is frequently called a term; because its duration or continuance, is bounded, limited, and determined. 2 Black. 143.

For every such estate must have a certain beginning, and certain end. If no day of commencement is named in the creation of this estate, it begins from the making, or delivery of the lease. A lease for so many years as such an one shall live, is void from the beginning; for it is neither certain, nor can it ever be reduced to a certainty, during the continuance of the lease. Id.

And the same doctrine holds, if a person makes a lease of his glebe for so many years as he shall continue parson of such a church, for this is still more uncertain. But a lease for twenty or more years, if the parson shall so long live, or if he shall so long continue parson, is good; for there is a certain period fixed, beyond which it cannot last, though it may determine sooner, on the parson's death, or his ceasing to be parson there. 2 Black. 143.

An estate for years, though ever so many, is inferior to an estate for life. For an estate for life, though it should be only for the life of another person, is a freehold; but an estate, though for a thousand years, is only a chattel, and reckoned part of the personal estate. Id.

Hence it follows, that a lease for years may be made to commence in futuro, though a lease for life cannot. As if I grant lands to one from Michaelmas next for twenty years, this is good; but to hold from Michaelmas next for the term of his natural life, is void. Id.

For no estate of freehold can commence in futuro, because it cannot be created at common law without livery of seisin, or corporal possession of the land; and corporal possession cannot be given of an estate now, which is not to commence now, but hereafter. And because no livery of seisin is necessary for a lease for years, such a lessee is not said to be seized, or to have true legal seisin of the lands. Nor indeed does the bare lease, vest any estate in the lessee, but only gives him a right of entry on the tenement, which right is called his interest in the term; but when he has actually so entered, and thereby accepted the grant, the estate is then and not before vested in him; and he is possessed, not properly of the land, but of the term of years, the possession or seisin of the land remaining still in him who has the freehold. 2 Black.

YELLOW. See Dyeing.

Yellow-hammer. See Emberiza.

YEOMAN, is defined to be one that has fee land of 40*s.* a-year; who was thereby heretofore qualified to serve on juries, and can yet vote for knights of the shire, and do any other act where the law requires one that is probus et legalis homo. Below yeomen are ranked tradesmen, artificers, and labourers. 2 Inst. 668.

Yeoman *of the guard*, one belonging to a sort of foot guards, who attend at the palace. The yeomen were uniformly required to be six feet high. They are in number 100 on constant duty, and 70 off duty. The one half carry arquebuses, and the other pertuisans. Their attendance is confined to the sovereign's person, both at home and abroad. They are clad after the manner of king Henry VIII.

The yeomen of the guards were anciently 250 men of the next rank, under gentry. This corps was first instituted by king Henry VII. anno 1466.

YEST, Yeast, or Barm, a head or scum, rising upon beer or ale, while working or fermenting in the vat. See Fermentation.

YEW. See Taxus.

YOKE, in agriculture, a frame of wood, fitted over the necks of oxen, whereby they are coupled together, and harnessed to the plough. See Plough.

It consists of several parts: as the yoke, properly so called, which is a thick piece of wood, lying over the neck; the bow, which compasses the neck about; the stitchings and wreathings, which hold the bow fast in the yoke; and the yoke-ring and ox-chain.

The Romans made the enemies they subdued, pass under the yoke, which they called sub jugum mittere, that is, they made them pass under a sort of furcæ patibulares, or gallows, consisting of a pike or other weapon, laid across two others, planted upright in the ground.

YORK. In the county of York, only one pannel of 48 jurors shall be returned to serve on the grand jury at the assizes; and at the quarter-sessions not above 40, either upon the grand jury or other service there. 7 and 8 W. III. c. 32.

And no person having 150*l.* a year, shall be summoned to the sessions, but only persons less liable to bear the expence of attending at the assizes. 1 Anne, c. 13.

By stat. 4 W. III. c. 2. the inhabitants of the province of York, have power to dispose of their personal estate by will; which before they had not, further than the testator's own proportionable part, called the dead man's or death's part. For if the testator had a wife, and a child, or children, the wife should have one third, the child or children another third, and the remaining third was all that the testator had to dispose of. If he had a wife and no child, then she should have one moiety, and the other moiety remained to him to dispose of by his testament; so if he left a child or children, and no wife. But if he had neither wife or child, he might dispose of the whole. In case of intestacy, the same proportions continue to the wife and children to this day; but the dead man's part shall be distributed according to the stat. 22 and 23 Car. II. c. 10. commonly called the statute of distributions.

YTTRIA. Some time before 1788, Captain Arhenius discovered in the quarry of Ytterby in Sweden, a peculiar mineral different from all those described by mineralogists. Its colour is greenish-black, and its fracture like that of glass. It is magnetic, and generally too hard to be scratched by a knife. It is opaque, except in small pieces, when it transmits some yellow rays. Its specific gravity is 4.237. Professor Gadolin analysed this mineral in 1794, and found it to contain a new earth; but though his analysis was published in the Stockholm Transactions for 1794, and in Crell's Annals for 1796, it was some time before it drew the attention of chemical mineralogists. The conclusions of Gadolin were confirmed by Ekeberg in 1707, who gave to the new earth the name of yttria. They were still farther confirmed and extended by Vauquelin in 1800, and likewise by Klaproth about the same time; and Ekeberg has published a new dissertation on the subject in the Swedish Transactions for 1802. We may therefore consider the peculiar nature of yttria as sufficiently established.

Hitherto yttria has been found only in the black mineral first analysed by Gadolin, and hence called gadolinite, in which it is combined with black oxide of iron and the earth called silica; and in yttrotantalite, which from the description of Ekeberg is a compound of tantalium and yttria. Both these minerals occur only in the quarry of Ytterby. From the first, which is the most common, the earth may be procured by treating the mineral reduced to powder with a mixture of nitric and muriatic acids, till it is completely decomposed; then filtring the solution, previously evaporated nearly to dryness, and then diluting it with water. By this process the silica is left behind. The liquid which passes through the filtre is to be evaporated to dryness, and the residue heated to redness for a considerable time in a close vessel, and then redissolved in water and filtred. What passes through the filtre is colourless; when treated with ammonia, pure yttria falls.

Yttria, thus procured, has the appearance of a fine white powder, and has neither taste nor smell. It is not melted by the application of heat. It has no action on vegetable blues. It is much heavier than any of the other earths; its specific gravity according to Ekeberg, being no less than 4.842.

It is insoluble in water; yet it is capable of retaining a great proportion of that liquid, as is the case with alumina. Klaproth ascertained, that one hundred parts of yttria precipitated from muriatic acid by ammonia, and dried in a low temperature, lose thirty-one parts, or almost a third of their weight, when heated to redness in a crucible. Now this last consists of pure water alone.

It is not soluble in pure alkalies; but it dissolves readily in carbonat of ammonia, and in all the other alkaline carbonats. It combines with acids, and forms with them salts which have a sweet taste, and at the same time a certain degree of austerity. Some of these salts have a red colour. Yttria is the only earthy body known which has the property of forming coloured salts with acids.

Yttria is not altered by light, nor is it likely that it combines with oxygen. From the experiments of Klaproth, it does not appear to combine readily with sulphur; nor is it likely that it unites with any of the other simple combustibles.

We may take it for granted that it is not affected by azote; but it combines with muriatic acid, and forms a salt not capable of crystallizing. Its action on the metals and metallic oxides is unknown.

YTTROTANTALITE, a mineral found in the same place with gadolinite. It is in small kidney-form masses of the size of a hazel-nut. Fracture granular, iron-grey, and of a metallic lustre. Hardness inconsiderable. May be scratched with a knife, and gives a grey-coloured powder. Not magnetic. Specific gravity 5.130. It is composed of the oxides of tantalium and iron united to yttria.

YUCCA, *Adam's needle*, a genus of plants of the class hexandria and order monogynia. The corolla is campanulate and patent, there is no style, the capsule is trilocular. There are four species, none of which are natives of Britain. All of them are exceedingly curious in their growth, and are therefore much cultivated in gardens. The Indians make a kind of bread from the roots of this plant.

YUNX, in zoology, a genus of birds of the order picæ. The bill is short, roundish, and pointed; the nostrils concave and naked; the tongue very long and cylindric; there are two fore and two hind claws. There is only one species, the torquilla, wry-neck, which is a native of Europe, Asia, and Africa, and is often seen in Britain. It is ash-coloured above, with light black and brown strokes; beneath light-brown, with black spots; tail ash-colour, with four black bars; weight 1 oz; irides hazel; length seven inches; migrates.

Z.

Z, the twenty-fourth and last letter of our alphabet.

In abbreviations this letter formerly stood as a mark for several sorts of weights; sometimes it signified an ounce and a half, and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram troy weight; and it has in earlier times been used to express the third part of an ounce, or eight scruples. ZZ were used by some of the antient physicians to express myrrh, and at present they are often used to signify zinziber, or ginger.

ZAFFRE, is the oxyde of cobalt, employed for painting pottery-ware and cobalt of a blue colour. See Cobalt.

ZAMIA, a genus of the natural order of palmæ. The ament. is shobile-shaped, scales with pollen underneath; fem. ament. shobile-shaped with scales at each margin; berry solitary. There are five species.

ZANNICHELLIA, horned pond-weed, a genus of the monœcia monandria class of plants, the male flower of which consists only of a single stamen; it has neither calyx nor corolla. In the female flower the calyx is composed of a single leaf; there is no corolla; the germina are about four; the seeds, which are oblong and acuminated on both sides, are as many. There is one species.

ZANONIA, the name of a genus of plants of the order diœcia, and class pentandria. The characters are these: it produces separate male and female flowers; in the male flower the cup is a perianthium, composed of three leaves of an oval figure, expanding every way, and shorter than the flower; the flower is monopetalous, but divided into five segments, and has an open mouth; the segments are jagged, and are equal in size, and bend backwards; the stamina are five filaments of the length of the cup, standing open at their end, and terminated by simple apices; the female flowers grow on separate plants, and have the cup and flower the same as in the male, only that the cup stands upon the germen of the pistil; this germen is oblong, and from it are propagated three reflex conic styles; the stigmata are bifid and curled; the fruit is a long and very large berry, truncated at the end, and very small at the base; it contains three cells, and has a curled suture near the apex; the seeds are two, they are of an oblong figure and flat. There is one species, the indica.

ZEA, *Indian corn*, a genus of plants of the class monœcia, order triandria. The male flowers are placed on distinct spikes; the calyx is a biflorous, beardless glume; the corolla is a beardless glume; the female calyx is a bivalve glume, as is the corolla. There is one filiform, pendulous style; the seeds are solitary and buried in an oblong receptacle. There is only species, the Mays, or maize. The Indians in New England, and many other parts of America, had no other vegetable but maize or Indian corn for making their bread. They call it weachin; and in the United States of America there is much of the bread of the country made of this grain, not of the European corn. In Italy, Germany, Spain and Portugal, maize constitutes a great part of the food of the poor inhabitants.

The ear of the maize yields a much greater quantity of grain than any of our corn-ears. There are commonly about eight rows of grain in the ear, often more, if the ground is good. Each of these rows contains at least thirty grains, and each of these gives much more flour than a grain of any of our corn. The grains are usually either white or yellowish; but sometimes they are red, blueish, greenish, or olive-coloured, and sometimes striped and variegated. This sort of grain, though so essentially necessary to the natives of the place, is yet liable to many accidents. It does not ripen till the end of September; so that the rains often fall heavy upon it while on the stalk, and birds in general peck it when it is soft and unripe. Nature has, to defend it from these accidents, covered it with a thick husk, which keeps off slight rains very well; but the birds, if not frightened away, often eat through it, and devour a great quantity of the grain.

ZEBRA. See Equus.

ZENITH, in astronomy, the vertical point; or a point in the heavens directly over our heads.

ZEOLITE. This stone was first described by Cronstedt in the Stockholm Transactions for 1756. It is sometimes found amorphous and crystallized. The primitive form of its crystal is a rectangular prism, whose bases are squares. The most common variety is a long four-sided prism, terminated by low four-sided pyramids.

Its texture is striated or fibrous. Its lustre is silky. Refracts double. Absorbs water. Specific gravity 2,0833. Colour white, often with a shade of red or yellow. When heated it becomes electric like the tourmaline. Before the blow-pipe it froths, emits a phosphorescent light, and melts into a white semi-transparent enamel, too soft to cut glass, and soluble in acids. In acids it dissolves slowly and partially without effervescence; and at last, unless the quantity of liquid is too great, it is converted into a jelly. A specimen of zeolite, analysed by Vauquelin, contained

53.00	silica
27.00	alumina
9.46	lime
10.00	water
99.46.	

ZEUS, in ichthyology, a genus of fishes of the order of thoracici. The head is compressed and declines, the upper lip being vaulted over by a transverse membrane; the tongue is subulated; there are seven rays in the gill-membrane; and the body is compressed. The species are eight; of which the most remarkable is the faber or doree. It is of a hideous form; its body is oval, and greatly compressed on the sides; the head large; the snout vastly projecting; the mouth very wide; the teeth very small; the eyes great, the irides yellow; the lateral line oddly distorted, sinking at each end, and rising near the back in the middle; beneath it on each side is a round black spot. The tail is round at the end, and consists of fifteen yellow rays. The colour of the sides is olive, varied with light blue and white, and while living is very resplendent, and as if gilt; for which reason it is called the doree. The largest fish we have heard of weighed twelve pounds. See Plate Nat. Hist. fig. 421.

ZIERIA, a genus of plants of the class and order tetrandria monogynia. The cal. is four-parted; petals four; styles simple; caps. four; seeds arilled. There is one species, not deserving notice.

ZINC. The antients were acquainted with a mineral to which they give the name of cadmia, from Cadmus, who first taught the Greeks to use it. They knew that when melted with copper it formed brass; and that when burnt, a white spongy kind of ashes was volatilized, which they used in medicine. This mineral contained a good deal of zinc; and yet there is no proof remaining that the antients were acquainted with that metal. The word zinc first occurs in the writings Paracelsus, who died in 1541. He informs us very gravely, that it is a metal, and not a metal, and that it consists chiefly of the ashes of copper. This metal has also been called spelter.

Zinc has never been found in Europe in a state of purity, and it was long before a method was discovered of extracting it from its ore. Henkel pointed out one in 1721; Von Swab obtained it by distillation in 1742; and Margraf published a process in the Berlin Memoirs in 1746.

Zinc is of a brilliant white colour, with a shade of blue, and is composed of a number of thin plates adhering together. When this metal is rubbed for some time between the fingers, they acquire a peculiar taste, and emit a very perceptible smell. Its hardness is six and a half. When rubbed upon the fingers it tinges them of a black colour. Its specific gravity, after it has been melted, is 6.861; after it has been compressed 7.1908; so that its density is increased 1-20th.

This metal forms in a manner the limit between the brittle and the malleable metals. Its malleability is by no means to be compared with that of some of the metals; yet it is not brittle, like others. When struck with a hammer, it does not break, but yields and becomes somewhat flatter; and by a cautious and equal pressure, it may be reduced to pretty thin plates, which are supple and elastic, but cannot be folded without breaking. This property of zinc was first ascertained by Mr. Sage. When heated to about 400°, it becomes so brittle, that it may be reduced to powder in a mortar.

It is not ductile. Its tenacity has not been ascertained. When heated to the temperature of about 700°, it melts; and if the heat is increased, it evaporates, and may be easily distilled over in close vessels. When allowed to cool slowly, it crystallizes in small bundles of quadrangular prisms, disposed in all directions. If they are exposed to the air while hot, they assume a blue changeable colour.

When exposed to the air, its lustre is soon tarnished, but it scarcely undergoes any other change. When kept under water its surface soon becomes black, the water is slowly decomposed, hydrogen gas is emitted, and the oxygen combines with the metal. If the heat is increased, the decomposition goes on more rapidly; and if the steam of water is made to pass over zinc at a very high temperature, it is decomposed so rapidly, that very violent detonations take place.

When zinc is kept melted in an open vessel, its surface is soon covered with a grey-coloured pellicle, in consequence of its combination with oxygen. When this pellicle is removed, another soon succeeds it; and in this manner may the whole of the zinc be oxidated. When these pellicles are heated and agitated in an open vessel, they soon assume the form of a grey powder, often having a shade of yellow. The powder has been called the grey oxide of zinc. When zinc is raised to a very strong red heat in an open vessel, it takes fire, and burns with a brilliant white flame, and at the same time emits a vast quantity of very light white flakes These are merely an oxide of zinc. This oxide was well known to the antients. Dioscorides describes the method of preparing it. The antients called it pompholyx; the early chemists gave it the name of nibil album, lana philosophica, and flowers of zinc. Dioscorides compares it to wool.

Two different oxides of zinc are at present known.

The peroxide, or white oxide of zinc, is the oxide usually formed in the different processes to which the metal is subjected. We are indebted to Mr. Proust for an exact analysis of this oxide and its combinations. It is composed of eighty parts of zinc and twenty of oxygen. It may be formed not only by burning zinc, but also by dissolving it in diluted sulphuric or nitric acid, and precipitating it by potass. This oxide is used as a paint; but its colour must be perfectly white. When zinc happens to contain a little iron, which is often the case with the zinc of commerce, the oxide obtained has a tinge of yellow, because it is mixed with a little yellow oxide of iron.

The protoxide, or zinc combined with a minimum of oxygen, is obtained by exposing the peroxide to a strong heat in an earthenware retort or covered crucible. From the experiments of Desormes and Clement, it appears that by this process zinc loses a portion of its oxygen, and assumes a yellow colour. According to the analysis of these chemists, the protoxide of zinc is composed of eighty-eight parts of zinc and twelve parts of oxygen. The reduction of the oxides of zinc is an operation of difficulty, in consequence of the strong affinity which exists between zinc and oxygen. It must be mixed with charcoal, and exposed to a strong heat in vessels which screen it from the contact of the external air.

Most of the simple combustibles combine with zinc.

Hydrogen gas dissolves a little of it in certain situations. It is usual to procure hydrogen gas by dissolving zinc in diluted sulphuric acid. The gas thus obtained is as pure as any which can be procured. It carries along with it however a little zinc in solution; but it deposits it again upon the sides of the glass jars, and on the surface of the water over which it stands. This gas, if we believe the French chemists, contains often a little carbureted hydrogen gas; a proof that zinc frequently contains carbon. When this metal is dissolved in sulphuric acid, it deposits a black insoluble powder, which the French chemists found to be carburet of iron. It is uncertain whether it is carburet, or carbon combined with zinc, which gives occasion to the production of the carbureted hydrogen gas.

It is believed at present that sulphur does not combine with zinc in the metallic state; because no attempt to form the combination artificially has succeeded. Sulphur unites with the oxide of zinc when melted along with it in a crucible. This was first discovered by Dehne in 1781. The experiment was afterwards repeated by Morveau. The sulphureted oxide of zinc is of a dark-brown colour, and brittle. It exists native in great abundance, and is known by the name of blende. Mr. Proust, however, has announced it as his opinion, that blende is a sulphuret of zinc, or a compound of sulphur and zinc in the metallic state.

Zinc may be combined with phosphorus, by dropping small bits of phosphorus into it while in a state of fusion. Pelletier, to whom we are indebted for the experiment, added also a little resin, to prevent the oxidation of the zinc. Phosphuret of zinc is of a white colour, and metallic splendour, but resembles lead more than zinc. It is somewhat malleable. When hammered or filed, it emits the odour of phosphorus. When exposed to a strong heat, it burns like zinc.

Phosphorus combines also with the oxide of zinc; a compound which Margraf had obtained during his experiments on phosphorus. When twelve parts of oxide of zinc, twelve parts of phosphoric glass, and two parts of charcoal-powder, are distilled in an earthenware retort, and a strong heat applied, a metallic substance sublimes of a silver-white colour, which when broken has a vitreous appearance. This, according to Pelletier, is phosphureted oxide of zinc. When heated by the blowpipe, the phosphorus burns, and leaves behind a glass, transparent while in fusion, but opaque after cooling.

Phosphureted oxide of zinc is obtained also when two parts of zinc and one part of phosphorus are distilled in an earthen retort. The products are, 1. Zinc; 2. Oxide of zinc; 3. A red sublimate, which is phosphureted oxide of zinc; 4. Needleform crystals of metallic brilliancy, and a blueish colour. These also Pelletier considers as phosphureted oxide of zinc.

Zinc does not combine with azote. Muriatic acid readily converts it into an oxide.

Zinc combines with almost all the metals, and some of its alloys are of great importance.

It may be united to gold in any proportion by fusion. The alloy is the whiter and the more brittle, the greater quantity of zinc it contains. An alloy, consisting of equal parts of these metals, is very hard and white, receives a fine polish, and does not tarnish readily. It has therefore been proposed by Mr. Malouin as very proper for the specula of telescopes. One part of zinc is said to destroy the ductility of 100 parts of gold.

Platinum combines very readily with zinc. The alloy is brittle, pretty hard, very fusible, of a blueish-white colour, and not so clear as that of zinc.

The alloy of silver and zinc is easily produced by fusion. It is brittle, and has not been applied to any use.

Zinc may be combined with mercury, either by triturating the two metals together, or by dropping mercury into melted zinc. This amalgam is solid. It crystallizes when melted, and cooled slowly into lamellated hexagonal figures, with cavities between them. They are composed of one part of zinc and two and a half of mercury. It is used to rub on electrical machines, in order to excite electricity.

Zinc combines readily with copper, and forms one of the most useful of all the metallic alloys. The metals are usually combined together by stratifying plates of copper and a native oxide of zinc combined with carbonic acid, called calamine, and applying heat. When the zinc does not exceed a fourth part of the copper, the alloy is known by the name of brass. It is of a beautiful yellow colour, more fusible than copper, and not so apt to tarnish. It is malleable, and so ductile that it may be drawn out into wire. Its density is greater than the mean. It ought to be by calculation 7.6296, but it actually is 8.3958; so that its density is increased by about 1-10th. When the alloy contains three parts of zinc and four of copper, it assumes a colour nearly the same with gold, but it is not so malleable as brass. It is then called pinchbeck, prince's metal, or prince Rupert's metal. Brass was known, and very much valued, by the antients. They used an ore of zinc to form it, which they called cadmia. Dr. Watson has proved that it was to brass that they gave the name of orichalcum. Their æs was copper, or rather bronze.

It is very difficult to form an alloy of iron and zinc. Wallerius has shewn that iron is capable of combining with a small portion of zinc; and Malouin has shewn that zinc may be used instead of tin to cover iron plates, a proof that there is an affinity between the two metals.

Tin and zinc may be easily combined by fusion. The alloy is much harder than zinc, and scarcely less ductile. This alloy is often the principal ingredient in the compound called pewter.

The alloy of lead and zinc has been examined by Wallerius, Gelert, Muschenbroeck, and Gmelin. This last chemist succeeded in forming the alloy by fusion. He put some suet into the mixture, and covered the crucible in order to prevent the evaporation of the zinc. When the zinc exceeded the lead very much, the alloy was malleable, and much harder than lead. A mixture of two parts of zinc and one of lead formed an alloy more ductile and harder than the last. A mixture of equal parts of zinc and lead, formed an alloy differing little in ductility and colour from lead; but it was harder and more susceptible of polish, and much more sonorous. When the mixture contained a smaller quantity of zinc, it still approached nearer the ductility and colour of lead; but it continued harder, more sonorous, and susceptible of polish, till the proportions approached to 1 of zinc and 16 of lead, when the alloy differed from the last metal only in being somewhat harder.

ZINNIA, a genus of plants of the class syngenesia, order polygamia superflua; and in the natural system arranged under the 49th order, composita. The receptacle is paleaceous, the pappus consists of two erect awns, the calyx is ovato-cylindrical and imbricated; the rays consist of five persisting entire florets. There are 5 species, none of them natives of Britain.

ZIRCON. This stone is brought from Ceylon, and found also in France and Spain, and other parts of Europe. It is commonly crystallized. The primitive form of its crystals is an octahedron, composed of two four-sided pyramids applied base to base, whose sides are isosceles triangles. The inclination of the sides of the same pyramid to each other is 124° 12′; the inclination of the sides of one pyramid to those of another 82° 50′. The solid angle at the apex is 73° 44′. The varieties of the crystalline forms of zircon amount to seven. In some cases there is a four-sided prism interposed between the pyramids of the primitive form; sometimes all the angles of this prism are wanting, and two small triangular faces in place of each; sometimes the crystals are dodecahedrons, composed of a flat four-sided prism with hexagonal faces, terminated by four-sided summits with rhomboidal faces; sometimes the edges of this prism, sometimes the edges where the prism and summit join, and sometimes both together, are wanting, and we find small faces in their place. For an accurate description and figure of these varieties, the reader is referred to Hauy.

The texture of zircon is foliated. Fracture imperfectly conchoidal. Causes a very great double refraction. Specific gravity from 4.615 to 4.383. Colours various, commonly reddish or yellowish; sometimes it is limpid. Before the blowpipe it loses its colour, but not its transparency. With borax it melts into a transparent glass. Infusible with fixed alkali and microcosmic salt.

1. The variety formerly called hyacinth is of a yellowish-red colour, mixed with brown. Its surface is smooth. Its lustre 3. Its transparency 3 to 4.

2. The variety formerly called jargon of Ceylon is either grey, greenish, yellowish brown, reddish brown, or violet. It has little external lustre. It is sometimes nearly opaque.

The first variety, according to the analysis of Vauquelin, is composed of

64.5	zirconia
32.0	silica
2.0	oxide of iron
98.5	

ZIZANIA, a genus of plants of the class monœcia, order hexandria; and in the natural system arranged under the 4th order, gramina. There is no male calyx; the corolla is a bivalved beardless glume, intermixed with the female flowers; there is no female calyx; the corolla is an univalved, cucullated, and aristated glume; the style is bipartite, and there is one seed covered with the plaited corolla. There are 2 species; the aquatica and terrestris, none of which are natives of Britain.

ZODIAC, See ASTRONOMY.

ZODIACAL *light*, a brightness sometimes observed in the zodiac, resembling that of the galaxy, or milky way. It appears at certain seasons, viz. towards the end of winter and in spring after sun-set, or before his rising in autumn and beginning of winter, resembling the form of a pyramid, lying lengthways with its axis along the zodiac, its base being placed obliquely with respect to the horizon. This phenomenon was first described and named by the elder Cassini, in 1683. It was afterwards observed by Fatio, in 1684, 1685, and 1686; also by Kirch and Eimmart, in 1688, 1689, 1691, 1693, and 1694.

ZOEGA, a genus of plants of the class syngenesia, and order polygamia frustranea. The receptacle is bristly; the pappus setaceous; the corollulæ of the radius ligulated; the calyx imbricated. There is one species, the leptaurea.

ZONE, in geography and astronomy, a division of the terraqueous globe, with respect to the different degree of heat found in the different parts.

A zone is the fifth part of the surface of the earth, contained between two parallels.

The zones are denominated torrid, frigid and temperate.

The torrid zone is a band surrounding the terraqueous globe, and terminated by the two tropics. Its breadth is 46° 58′. The equator, running through the middle of it, divides it into two equal parts, each containing 23° 29′. The antients imagined the torrid zone uninhabitable.

The temperate zones are two bands, environing the globe, and contained between the tropics and the polar circles: the breadth of each is 43° 2′.

The frigid zones are segments of the surface of the earth, terminated, one by the antarctic, and the other by the arctic circle. The breadth of each is 46° 58′.

ZONITIS, a genus of insects of the order coleoptera, The generic character is, antennæ testaceous; feelers four, filiform; jaw entire, longer than the feelers; lip emarginate. There are eight species.

ZOOLOGY, is that part of natural history which relates to animals.

In order to abridge the study of zoology, many methods of reducing animals to classes, genera, and species, have been invented: but as that of Linnæus is undoubtedly the best, the most extensive, and the most generally adopted, we shall give a brief account of it.

Linnæus divides the whole animal kingdom into six classes. The characters of these six classes are taken from the internal structure of animals, in the following manner:

Class I. *Mammalia*, includes all animals that suckle their young. The characters of this class are these: The heart has two ventricles and two auricles; the blood is red and warm; and the animals belonging to it are viviparous.

Class II. *Aves*, or birds. The characters are the same with those of class I. excepting that the animals belonging to it are oviparous.

Class III. *Amphibia*, or amphibious animals. The heart has but one ventricle and one auricle; the blood is red and cold; and the animals belonging to this class have the command of their lungs, so that the intervals between inspiration and exspiration are in some measure voluntary.

Class IV. *Pisces*, or fishes. The heart has the same structure, and the blood the same qualities, with those of the amphibia; but the animals belonging to this class are easily distinguished from the amphibia, by having no such voluntary command of their lungs, and by having external branchiæ or gills.

Class V. *Insecta*, or insects. The heart has one ventricle, but no auricle; the blood is cold and white; and the animals are furnished with antennæ or feelers. See INSECT.

Class VI. *Vermes*, or worms. The characters are the same with those of class V. only the animals have no antennæ, and are furnished with tentacula.

The first class, *Mammalia*, is subdivided into seven orders; the characters which are taken from the number, structure, and situation of the teeth.

Order I. The primates have four incisores. or fore teeth, in each jaw, and one dog-tooth, N. B. By one dog-tooth, Linnæus means one on each side of the fore-teeth in both jaws. This order includes four genera, viz. homo, simia, lemur, vespertilio.

Order II. The bruta have no fore-teeth in either jaw. This order includes seven genera, viz. rhinoceros, elephas, trichechus, bradypus, myrmecophaga, manis, dasypus.

Order III. The feræ have, for the most part, six conical fore-teeth in each jaw. This order includes ten genera, viz. phoca, canis, felis, viverra, mustela, ursus, didelphis, talpa, sorex, erinaceus.

Order IV. The glires have two fore-teeth in each jaw, and no dog-teeth. This order includes ten genera, viz. hystrix, lepus, castor, mus, sciurus, myoxus, cavia, arotomys, dypus, hyrox.

Order V. The pecora have no fore-teeth in the upper jaw, but six or eight in the under jaw. This order includes eight genera, viz. camelus, moschus, giraffa, cervus, antilope, capra, ovis, bos.

Order VI. The belluæ have obtuse fore-teeth in each jaw. This order includes four genera, viz. equus, hippopotamus, sus, tapir.

Order VII. The cete, or whale kind, have no uniform character in their teeth, being very different in the different genera; but are sufficiently distinguished from the other orders of mammalia, by living in the ocean, having pectoral fins, and a fistula or spiraculum upon the head. This order includes four genera, viz. monodon, balæna, physeter, delphinus.

The generic characters of the mammalia are, like those of the orders, almost entirely taken from the teeth, excepting the vespertilio, which, besides the character of the order derived from the teeth, has this farther mark, that there is a membrane attached to the feet and sides, by means of which the creature is enabled to fly: the hystrix, whose body is covered with sharp spines: and the whole order of pecora, whose genera, besides the characters taken from the teeth, are distinguished into those which have horns, those which have no horns, and by peculiarities in the horns themselves.

The specific characters are very various, being taken from any part of the body which possesses a peculiar uniform mark of distinction. As examples of these characters are to be found under the proper name of each genus, it is unnecessary to say any thing further concerning them in this place.

The second class, *Aves*, is subdivided into six orders; the characters of which are taken chiefly from the structure of the bill.

Order I. The accipitres have a hooked bill, the superior mandibule, near the base, being extended on each side beyond the inferior; and in some it is armed with teeth. This order includes four species, viz. vultur, falco, strix, lanius.

Order II. The picæ have a convex, compressed bill, resembling a knife. This order contains 23 genera, viz. trochilus, certhia, upupa, glaucopis, buphaga, sitta, oriolus, coracias, gracula, corvus, paradisea, ramphastos, trogon, psittacus, crotophaga, picus, yunx, cuculus, bucco, boceros, alcedo, merops, todus.

Order III. The anseres have a smooth bill, broadest at the point, covered with a smooth skin, and furnished with teeth: the tongue is fleshy; and the toes are palmated or webbed. This order includes 13 genera, viz. anas, mergus, phaeton, plotus, rhyncops, diomedea, aptenodyta, alca, procellaria, pelecanus, larus, sterna, colymbus.

Order IV. The grallæ have a somewhat cylindrical bill: the tail is short, and the thighs are naked. This order contains 20 genera, viz. phœnicopterus, platalea, palamedea, mycteria, tantalus, ardea, corrira, recurvirostra, scolopax, tringa, fulica, parra, rallus, vaginalis, psophia, cancroma, scopus, glareola, hæmatopus, charadrius.

Order V. The gallinæ have a convex bill; the superior mandible is vaulted over the inferior: the nostrils are half covered with a convex cartilaginous membrane: and the feet are divided, but connected, at the inmost joint. This order contains 10 genera, viz. struthio, didus, pavo, meleagris, penelope, crax, phasianus, numida, tetrao.

Order VI. The passeres have a conical sharp pointed bill; and the nostrils are oval, wide, and naked. This order contains 17 genera, viz. loxia, colius, fringilla, phytotoma, emberiza, caprimulgus, hirundo, pipra, turdus, ampelis, tanagra, mucicapa, parus, motacilla, alauda, sturnus, columba.

The generic characters of this class are taken from peculiarities in the bill, the nostrils, the tongue, the feet, the feathers, the face, the figure of the body, &c.

The characters which serve to distinguish the species are very various: for example, the colour of the particular feathers or parts of feathers; crests of feathers on the head, disposed in different manners; the colour of the cere or wax; the colour of the feet; the shape and length of the tail; the number, situation, &c. of the toes; the colour and figure of the bill, &c.

The third class, *Amphibia*, is divided into two orders.

Order I. The reptiles have four feet, and breathe by the mouth. This order contains four genera, viz. testudo, draco, lacerta, rana.

Order II. The serpentes have no legs, and breathe by the mouth. This order contains six genera, viz. crotalus, boa, coluber, anguis, amphisbæna, cæcilia.

The generic characters of this class are taken from the general figure of the body; from their having tails or no tails; being covered with a shell; having teeth or no teeth in the month; being furnished with lungs; having covered or naked bodies; from the number, situation, and figure of the scuta and scales; from the number and situation of the spiracula; from the situation of the mouth, &c.

The specific characters are so very various, that it would be superfluous to enumerate them.

The fourth class, *Pisces*, is subdivided into six orders, the characters of which are taken from the situation of the belly fins.

Order I. The apodes have no belly fins. This order contains eight genera, viz. muræna, gymnotus, trichiurus, anarchichas, ammodytes, ophydium, stromateus, xiphias, sternoptyx, leptocephaius.

Order II. The jugulares have the belly fins placed before the pectoral fins. This order includes five genera, viz. callionymus, uranoscopus, trachinus, gadus, blennius, kurtus.

Order III. The thoracici have the belly fins placed under the pectoral fins. This order comprehends nineteen genera, viz. cepola, echeneis, coryphæna, gobius, cottus, scorphæna, zeus, pleuronectes, chætodon, sparus, scarus, labrus, sciæna, perca, gasterosteus, scomber, centrogaster, mullus, trigla.

Order IV. The abdominales have the belly fins placed behind the pectoral fins. This order contains sixteen genera, viz. cobitis, amia, silurus, teuthis, loricaria, salmo, fistularia, esox, elops, argentina, atherina, mugil, exocætus, polynemus, clupea, cyprinus.

Order V. The branchiostegi have the gills destitute of bony rays. This order contains ten genera, viz. mormyrus, ostracion, tetrodon, diodon, syngnathus, pegasus, centriscus, balistes, cyclopterus, lophius.

Order VI. The chondropterygii have cartilaginous gills. This order contains five genera, viz. accipenser, chimæra, squalus, raia, ptromyzon.

The generic characters of this class are taken from peculiarities in the head, the mouth, the teeth, the nostrils, the rays in the membrane of the gills, the eyes, the general figure of the body, the figure of the tail, the situation of the spiracula, &c.

The specific characters are taken from peculiarities in all the parts above enumerated, and many others.

The fifth class, *Insecta*, is subdivided into seven orders, the characters of which are taken from the wings. See the article INSECT.

Order I. The coleoptera have four wings, the two superior ones being crustaceous, and furnished with a straight suture. This order comprehends forty-seven genera, viz. scarabæus, lucanus, dermestes, melyris, byrrhus, silpha, tritoma, hydrophilus, hister, pausus, bostrichus, anthrenus, nitidula, coccinella, curculio, brentus, attelabus, erodius, staphylinus, scaurus, zygia, meloe, tenebrio, cassida, opatrum, mordella, chrysomela, horia, apalus, manticora, pimelia, gyrinus, cucujus, cryptocephalus, bruchus, ptinus, hispa, buprestis, necydalis, lampyris, cantharis, notoxus, elater, calopus, alurnus, carabus, lytta, serropalpus, cerambyx, leptura, rhinomacer, zonitis, cicindela, dyticus, forficula.

Order II. The hemiptera have four wings, the two superior ones being semicrustaceous and incumbent, *i. e.* the interior edges lie above one another. This order includes fourteen genera, viz. blatta, pneumora, mantis, gryllus, fulgora, cicada, notonecta, nepa, cimex, macrocephalus, aphis, chermes, coccus, thrips.

Order III. The lepidoptera have four wings, all of them imbricated with scales. This order contains three genera, viz. papilio, sphinx, phalæna.

Order IV. The neuroptera have four wings, interwoven with veins, like a piece of network, and no sting in the anus. This order includes seven genera, viz. libella, ephemera, hemerobius, myrmelion, phryganea, panorpa, rophidia.

Order V. The hymenoptera have the same characters with the former, only the anus is armed with a sting. But this mark is peculiar to the females and neuters; for the males have no sting. This order comprehends fifteen genera, viz. cynips, tentredo, sirex, ichneumon, sphex, scolia, thynnus, leucospis, tiphia, chalcis, chrysis, vespa, apis, formica, mutilla.

Order VI. The diptera have two wings, and two clavated halteres or balances behind each wing. This order contains twelve genera, viz. diopsis, tipula, musca, tabanus, empis, conops, oestrus, asilus, stomoxys, culex, bombylius, hippobosca.

Order VII. The aptera have no wings. This order contains fifteen species, viz. lepisma, podura, termes, pediculus, pulex, acarus, hydrachna, aranea, phalangium, scorpio, cancer, monoculus, oniscus, scolopendra, julus.

The sixth class, *Vermes*, is divided into five orders.

Order I. The intestina are the most simple animals, being perfectly naked, and without limbs of any kind. This order contains twenty-one genera, viz. ascaris, trichocephalus, uncinaria, tilaria, scolex, ligula, linguatula, strongylus, echinorhynchus, hæruca, cucullanus, caryophyllæus, fasciola, tænia, furia, myxine, gordius, hirudo, lumbricus, sipunculus, planaria.

Order II. The mollusca are likewise simple naked animals, without any shell; but they are brachiated, or furnished with a kind of limbs. This order comprehends thirty-one genera, viz. actinia, clava, mammaria, pedicellaria, ascidia, salpa, dagysa, pterotrachea, limax, aplysia, doris, tethys, holothuria, terebella, triton, sepia, clio, lobaria, lernæa, scyllæa, glaucus, ahprodita, amphitrite, spio, nereis, nais, physsophora, medusa, lucernaria, asterias, echinus.

Order III. The testacea have the same characters with those of order II. but are covered with a shell. This order includes 36 genera, viz. chiton, lepas, pholas, mya, solen, tellina, cardium, mactra, donax, venus, spondylus, chama, arca, ostrea, anomia, mytilus, pinna, argonauta, nautilus, conus, cypræa, bulla, voluta; buccinum, strombus, murex, trochus, turbo, helix, nerita, haliotis, patella, dentalium, serpula, teredo, sabella.

Order IV. The zoophyta, are compound animals, furnished with a kind of flowers, and having a vegetating root and stem. This order contains 15 genera, viz tubipora, madrepora, millepora, cellepora, isis, antipathos, gorgonia, alcyonium, spongia, flustra, tubularia, corralina, sertularia, pennatula, hydra.

Order V. The infusoria consists of very small simple animals. This order contains 15 genera, viz. brachionus, vorticella, trichoda, cercaria, leucopera, gonium, colpoda, paramecium, cyclidium, bursaria, vibrio, enchelis, bacillaria, volvox, monas.

For more particular information concerning the several branches and subjects of zoology, the reader may consult the various articles above referred to, and he will find most of the genera described in their order in the alphabet.

ZOOPHYTE, in natural history, the 4th order of the class of vermes. See ZOOLOGY.

ZOSTERA, a genus of plants of the class gynandria, order polyandria; and in the natural system arranged under the second order, piperitæ. The spadix is linear, and fertile only on one side; there is no calyx nor corolla; the stamina are alternate; the seeds solitary and alternate. There is one species.

ZWINGERA, a genus of the class and order of plants decandria monogynia. The calyx is five-parted; petals five; capsules five. There is one species, the amasa, resembling quassia, a shrub of Guiana.

ZYGÆNA. See SQUALUS.

ZYGIA, a genus of insects of the order coleoptera. The generic character is, antennæ moniliform: feelers equal, filiform: lip elongated, membranaceous: jaw one-toothed.

ZYGOPHYLLUM, bean-caper, a genus of plants of the class of decandria and order monogynia, and in the natural system arranged under the 14th order, gruinales. The calyx is five-leaved; petals five; nectarium ten-leaved, covering the germ; capsules five-celled. There are 14 species, partly shrubby and partly herbaceous plants, all natives of warm climates, though some of them are hardy enough to endure the open air in this country.

The Binder is requested to place the PLATES *in the following order:—*

ERRATA.

VOL. I. Page 15, col. 2, under Action, line 28 from the top, *for* against *read* by.
19, col. 3, under Adoxia, *for* Adoxia *read* Adoxa.
23, col. 3, under Æther, line 3 from the bottom, *for* rarefied *read* rectified.
47, col. 3, under Alehouses, line 8 from the top, *for* 40*s.* *read* 20*l.* and dele the rest of the sentence.
48, col. 1, under Alexandrian MS. line 23 from the head of the article, *for* Dr. Warde *read* Dr. Woide.

VOL. II. Page 37, col. 2, under Lord's Day, line 14 from the head of the article, *for* 20*l.* *read* 20*s.*
225, col. 3, under Mortmain, line 2 from the bottom, *for* debt *read* death.
243, col. 3, under Musk, lines 9 and 10 from the top, *for* into a kind *read* in a gland.
255, col. 3, under Natural Philosophy, line 7 from the head of the article, *for* compounded *read* confounded.
Ditto, ditto, line 2 from the bottom of ditto, *for* astonomy *read* astronomy.
280, col. 2, under Nymphæ, third article in the column, *for* Nymphæ *read* Nymphæa.
827, line 1, *dele* See Plate II. figs. 1 and 2.
Ditto, line 19 from bottom, *dele* Plate II. figs. 1 and 2.

BOOKS

Lately Published by RICHARD PHILLIPS, No. 6, Bridge-street, London.

UNIVERSAL HISTORY, Ancient and Modern, from the earliest Records of Time to the General Peace of 1802; complete in Twenty-five Volumes, embellished with Plates, and illustrated with Maps, Indexes, and Chronological Tables.

By WILLIAM MAVOR, LL. D.
Vicar of Hurley, in Berkshire; Rector of Stonesfield, Oxon; Chaplain to the Earl of Moira, &c. &c.

There are Two Editions; which may be had done up in three kinds of Binding, at the following Prices:

Common Paper	in Boards	£.4	13	6
Ditto, Ditto	half bound	5	0	0
Ditto, Ditto	calf gilt	5	15	6
Fine and Large Paper	in Boards	6	5	0
Ditto, Ditto	half bound	6	16	6
Ditto, Ditto	calf gilt	7	10	0

In the Execution of this extensive and arduous Undertaking, through all its parts, the Editor has been solicitous to keep at an equal distance from Prolixity and Brevity. He has studied to be clear, distinct, comprehensive, and exact. To all persons, therefore, who wish to possess at a moderate Expence, a complete body of Universal History, brought down to the present Time; to Schools in particular, to Students, and to circulating and private Libraries; the Work will unquestionably prove a valuable and desirable acquisition.

THE HISTORY of GREAT BRITAIN, from THE REVOLUTION in 1688 (when Hume's History terminates), to THE PEACE OF AMIENS in 1802. A New Edition, printed in Twelve Volumes, octavo, uniformly with the History of Mr. Hume, price Six Guineas in boards; or any two Volumes separately, price 21s. in boards.

By WILLIAM BELSHAM, ESQ.

Mr. HUME's History was brought by that writer down to the period of the Revolution, and Mr. BELSHAM has taken up the narrative from the Revolution and brought it down to the Peace of Amiens.

Both works form an uniform Series of Twenty Volumes; and they may be had of every Bookseller in Town and Country, price NINE GUINEAS in boards.

Persons already possessing Mr. Hume's History, may have Mr. Belsham's entire Work by itself, in Twelve Volumes, for SIX GUINEAS in boards.

And as the latter part of Smollett's General History was frequently sold, previously to the appearance of Mr. Belsham's Work, as a Continuation of Hume to the Death of George the Second, Mr. Phillips thinks it proper to observe, that Mr. Belsham's History of the Reign of George the Third may be had separately, to complete Hume and Smollett, in Eight Volumes, price FOUR GUINEAS in boards.

THE LIFE of GEORGE WASHINGTON, Commander in Chief of the American Forces during the War which established the Independance of his Country, and First President of the United States of America; compiled under the Inspection of his Nephew and Heir, the HONOURABLE BUSHROD WASHINGTON, from original papers, bequeathed to him by his deceased relative; in two Editions: one in superb medium quarto, price Seven Guineas and a Half in boards, and another in demy octavo, price Two Guineas and a Half in boards; the whole illustrated with numerous Views, Maps, and Plans.

By JOHN MARSHALL,
Chief Justice of the United States, &c. &c.

MODERN LONDON: consisting of a Brief History of the Metropolis of the British Empire, and of A full and circumstantial Description of its PRESENT STATE; illustrated by beautiful characteristic Engravings, representing all the Places of great public Resort, and the principal Buildings: in one large and elegant Quarto Volume, illustrated with Sixty Engravings, by the first Artists, plain and coloured, price Three Guineas in boards.

This Work is the only existing Publication of sufficient Consequence and Authority to illustrate to Foreigners and Strangers the Wealth, Splendour, Population, and Magnitude, of the largest City in the World. It was published expressly with that Design; and it is calculated to convey to the remotest Nations the clearest Ideas relative to London, and to preserve the Recollection of its most interesting Features to those persons who are or have been familiar with them.

THE FARMER's CALENDAR; containing a full Account of the BUSINESS necessary to be performed on all kinds of Farms during EVERY MONTH of the YEAR, with the latest Improvements, and the Mode of executing them. The Sixth Edition, improved; in One large Volume, octavo, price Half a Guinea in boards.

By ARTHUR YOUNG, Esq. F. R. S.
Secretary to the Board of Agriculture, and Member of various Philosophical and Agricultural Societies in Europe and America.

A COMPLETE SYSTEM of PRACTICAL AGRICULTURE; including all the MODERN IMPROVEMENTS and DISCOVERIES, and the results of all the attention and inquiry which have been bestowed on this important Science, during the last thirty years; the whole combining and explaining fully, extensively, and completely, the PRINCIPLES and PRACTICE of the MODERN ART OF HUSBANDRY in all its branches and relations. A new and improved Edition, in two large volumes quarto, illustrated with nearly One Hundred Engravings, representing the most improved Implements, the various Grasses, and the principal Breeds of Sheep and Cattle, price Four Guineas in Boards.

By R. W. DICKSON, M. D.
Honorary Member of the Board of Agriculture.

CARR's TRAVELS IN IRELAND.

THE STRANGER in IRELAND, or a Tour through the Southern and Western Parts of that Country, in the Year 1805; containing Views of the State of Society, Manners, and Opinions, among the People of Ireland, interspersed with numerous characteristic Anecdotes. In an elegant Volume quarto, decorated with Seventeen beautiful Engravings, price 45s. in Boards.

By SIR JOHN CARR.

TRAVELS ROUND the BALTIC, through DENMARK, SWEDEN, RUSSIA, POLAND, and PRUSSIA; with numerous Plates, price 42s. in boards.

By SIR JOHN CARR.

AN ILLUSTRATION of the ANATOMY of the HUMAN EAR, accompanied by VIEWS of that ORGAN, accurately drawn, of the Natural Size, from a Series of Dissections. To which is added, a TREATISE on its DISEASES, the Causes of Deafness, and the proper Treatment, price 25s. in Boards, elegantly printed in One Volume folio, with splendid Engravings by Heath.

By J. C. SAUNDERS,
Demonstrator of Practical Anatomy in the Anatomical School in St. Thomas's Hospital, and Surgeon to the London Dispensary for Diseases of the Eye and Ear.

TRAVELS IN GERMANY, HOLLAND, FLANDERS, AND FRANCE, TO PARIS: With numerous particulars, relative to the Present State of that Capital; its Festivals, Literature, Characters, Paintings, Music, Theatres, Gardens, Institutions, Architecture, and especially the Manners of the People, &c. &c. In two elegant Volumes, Quarto, decorated with a great number of Vignettes, with a separate Atlas of large and splendid Engravings, representing the principal Objects and Buildings in Paris, price Eight Guineas in boards; or, with the Plates reduced in size, and folded in the Volumes, price Five Guineas in boards.

By THOMAS HOLCROFT.

ANIMAL BIOGRAPHY: or, ANECDOTES and CURIOUS FACTS, relative to the Manners, Habits, and Economy, of the WHOLE ANIMAL CREATION, collected from works of Authority in all Languages, from expensive books of Natural History, from Voyages and Travels, and from every authentic Source. The whole classed and arranged according to the system of Linnæus. A new Edition, considerably extended and improved, in Three large Volumes, 8vo., price 1l. 10s. in boards.

By the Rev. W. BINGLEY,
Fellow of the Linnæan Society, and late of St. Peter's College, Cambridge.
